Quietism [Lat. *quies*, rest]: Ger. *Quietismus*; Fr. *quétisme*; Ital. *quietismo*. A form of MYSTICISM (q. v.) which lays emphasis upon the passive and receptive attitude of the human spirit in relation to the influx of the divine Spirit, and making little or nothing of activity in religious matters, whether ceremonial or moral activity, and everything of contemplation.

It made the Sabbath a symbol of rest in God. Its aim was the absorption of the practical personality in God. Its chief representatives are Angelus Silesius and Molinix. The influence of the latter, a Spanish priest, was considerable in the Roman Catholic Church. Cf. PATRISTIC PHILOSOPHY, ad fin., also ST. THOMAS (philosophy of). Fénelon represented it until it was condemned by the pope under the influence of Bossuet. Madame Guyon is its chief literary representative. It is somewhat akin to PIETISM (q. v.) and to the religious philosophy of the Friends. (J.D.)

Quinque voces: see PREDICABLE.

R

RABBINISM — RACE

Rabbinism [Heb. *Rabbi*, from *rab*, much]: Ger. *Rabbinismus*; Fr. *rabbinisme*; Ital. *rabbinismo*. A doctrinal system which arose among the Jews after their return from the Babylonian captivity, the essential feature of which was the claim that oral tradition is necessary to supplement the law of Moses and is of equal authority with it.

Rabbinism arose out of the necessity of adapting the written law to the conditions of the life of the people. It gave rise to a body of traditional interpretations and regulations embodied in the Mishna, the Talmud, and later, the Cabala. The Rabbinical movement is divisible into two great periods: (1) that of development, during which the principal Rabbinical books were produced. This period ended with the 5th century A.D. (2) That of application and further interpretation, embracing the subsequent period during which the creation of new traditional matter had practically ceased.

Literature: McCaul, *Sketches of Judaism and the Jews* (London, 1838); Concise Dict. of Religious Knowledge, art. Jews; McClintock and Strong's Cyc. of Bibl. Knowledge, art. Rabbinism; Jost, *Gesch. d. Judenthums u. seiner Sekten* (1857-9).

Rabies [Lat. *rabies*, rage]: Ger. *Hundswuth*; Fr. *rage*; Ital. *rabbia*. The disease following the introduction of a specific poison, most usually occasioned by the bite of a rabid dog; and which from one of its symptoms in man—namely, the paroxysm caused by the attempt to swallow, and the consequent dread of water—is also termed hydrophobia.

The period of incubation intervening between the introduction of the poison and

the appearance of the symptoms is stated to be on the average from six weeks to three months. Death often ensues within two or three days after the onset of the marked symptoms. The mental symptoms are definite, beginning as a rule with an ill-defined dread or suspicion that something is wrong, and followed by hallucinations, mainly of sight and hearing. The stage of hallucination is followed by that of excitation or mania, which is slight in some cases, and in others leads to destructiveness, delirium, &c. If the patient survives the stage of excitation there ensues the stage of exhaustion, marked by paralysis, usually proceeding from the lower nerve-centres upward. It is during the stage of excitation that the hydrophobic and spasmodic symptoms appear.

There is also noted a pseudo or hysterical hydrophobia, which imitates the usual symptoms but differs from them in some details. The history of the bite may be uncertain; the patient is apt to talk constantly about the dog and the bite; the true respiratory spasm does not appear; the excited condition may last days or even weeks, and so on.

One of the most interesting characteristics of rabies is that the mental symptoms offer a close parallelism in man and in the higher animals. A dog stricken with rabies exhibits all evidences of the periods of hallucination, excitation, and paralysis. (J.J.)

Race [MHG. *reiz*, line, scratch; Lat. *radix*, root]: Ger. *Rasse*; Fr. *race*; Ital. *razza*. (1) In biology: family (q.v. under CLASSIFICATION, in biology), e.g. the human race or family Hominidae.

(2) In ethnology: those divisions of the

human family which are, biologically considered, varieties.

For special usages see RACE PSYCHOLOGY.

(J.J.—J.M.B.)

In ethnology, race is a general term, and is sometimes contrasted with people or nation. Owing to the migrations and interminglings of all sorts, pure-bred races are very few and difficult to establish. Hence the term race has a relative rather than an absolute value, and refers to a naturally homogeneous, ethnic division of the human family. The most common classification is that of Blumenbach (1781) into Caucasian, Mongolian, Ethiopian, American, and Malay. Cuvier distinguished only Caucasian, Mongol, and Negro. Both of these have been criticized as unsatisfactory by modern ethnologists, who have not, however, agreed upon any uniform classification. Such a distinction as that given by Huxley into Australoid, Negroid, Mongoloid, Xanthocroic, and Melanochroic is more accurate but less easily applied. The further discussion of the nature and differentiation of races at once involves the questions of the selection of differentia, whether colour, anatomical characteristics, language, customs and institutions, habitat, and the like; the question of the original unity of the human race and its centres of dissemination; the question of the origin of the family, and the mode of derivation of kinship; and other questions of similar import which belong to the science of ETHNOLOGY (q. v.).

Other terms similar in connotation to race, but narrower in extent, are clan, tribe, branch, stock, and family.

Literature: see works cited under ETHNOLOGY and ETHNOGRAPHY; KEANE, *Ethnology* (1896); and Man, Past and Present (1899); RIPLEY, *The Races of Europe* (1899). An important recent work is EHRENREICH, *Anthropol. Stud. ü. d. Urbewohner Brasiliens*, Einleitung. (J.J.)

Race Experience: see RACE PSYCHOLOGY.

Race Psychology: Ger. *Rassenpsychologie*; Fr. *psychologie des races*; Ital. *psicologia delle razze*, *etnopsicologia* (suggested—E.M.). That branch of PSYCHOLOGY (q. v.) which uses as data the manifestations of mind in the various species and races of animals and man.

It is broader than FOLK PSYCHOLOGY (q. v.), which treats of the psychology of human groups only. Race psychology considers the problems of the evolution of mind from its simplest forms—of mental descent analogous

to biological DESCENT (q. v.). This usage follows the connotation of 'race experience' used by Spencer for the accumulated experience of successive generations, and has been explicitly adopted by one of the present writers. Cf. EVOLUTION (mental), and COMPARATIVE PSYCHOLOGY.

Literature: SPENCER, *Princ. of Psychol.*; BALDWIN, *Ment. Devel. in the Child and the Race*; also citations under EVOLUTION (mental). (G.F.S.—J.M.B.)

Radiance: see ETHER.

Radiation [Lat. *radiatio*]: Ger. *Strahlung*, *eingeschaltete Neuronen*; Fr. *radiations*, *couronne rayonnante* (more special—Y.D.); Ital. *radiazione*. The fibres connecting the primary with a secondary sensory centre.

Thus the tracts from the olfactory lobe to the hippocampus, and those from the geniculate body to the cortical visual centre, are radiations. The radiations taken together are called the 'projection system,' the lower centres being projected upon the cortex. Cf. RADIX. (H.H.—J.M.B.)

Radicalism: see LIBERALISM.

Radix [Lat. *radix*, a root]: Ger. *Wurzel*; Fr. *racine*; Ital. *radice*. Bundles of nerve-fibres at the point of emergence from or entrance into the central nervous system. Especially the portion of a peripheral nerve between a spinal or cranial ganglion and the central organ. A nerve-root. Cf. RADIATION.

Several of the nerves of special sense are simply roots, there being no peripheral course distinct from the ganglion. Thus the optic nerve is composed of root-fibres connecting the ganglion in the retina with the primary optic centre. The case of the olfactory nerve is obscure, though probably essentially the same as the optic, except that the homologue of the ganglion is diffuse rather than distinctly localized. (H.H.)

Raison d'être [Fr.]: 'Reason for being.' Used in English in the general sense of justification, utility, 'why and wherefore.' Not a precise term. (J.M.B.)

Ramundus Lullus, or **Raimon Lul** or **Lulli**: cf. LULLY, RAYMUNDUS.

Ramus, Petrus (Pierre de la Ramée). (1515–72.) Studied at the University of Paris. He attacked Aristotle and scholastic philosophers, and was forbidden for a time to teach. Later he received an appointment at the University. Embraced Protestantism, 1561. Died in the massacre of St. Bartholomew.

Range (of stimulation and sensation) [Fr. *ranger*, from *rang*, row]: Ger. *Umfang*, *Reiz-*

umfang, &c.; Fr. *étendue de l'excitation* (&c.); Ital. *ampiezza* (or *estensione*) *della sensazione* (&c.). (1) Of stimulation: the entire region of those values of stimuli a change in which is accompanied by a change in sensation. It includes the entire series of stimulus values which are effective for the production of sensation from the lower to the upper limen or THRESHOLD (q. v.) values.

(2) Of sensation: the corresponding continuum of sensations. Cf. LIMITS (of stimulation and sensation).

The determination of the range of sensation is much complicated by the relativity of the THRESHOLD, which is remarked upon under that term. (C.L.F., J.M.B.)

Rapport (hypnotic) [Fr.]: the Fr. term is used in English and German; Ital. *rapporto* (*magnetico*). The peculiar relation sustained by a hypnotized person to the hypnotizer during HYPNOSIS (q. v., also for literature).

It is a strong point in favour of the 'suggestion' theory of hypnosis that the 'rapport' may be transferred by suggestion from the hypnotizer to a third person. (J.M.B.)

Ratio [Lat. *ratio*, calculation, relation, reason, doctrine]: Ger. *Verhältniss*; Fr. *rapport*; Ital. *rapporto*. The following relation between quantities: the ratio of *A* to *B* is the same as that of *C* to *D* when the quotient of *A* divided by *B* is equal to the quotient of *C* divided by *D*; hence often equivalent to quotient, or fraction. (C.S.P.)

The word is not used in the senses equivalent to the Latin *ratio*, meaning REASON (q. v.). (J.M.B.)

Ratiocination [Lat. *ratio*, reason]. REASONING (q. v., also for foreign equivalents).

So the Schoolmen. Thus, Aquinas says it is 'quidam motus intellectus transeuntis ab uno in aliud,' which, however inexact in expression, conveys a clear idea. J. S. Mill confines the term to the process of necessary inference, because he is unwilling to admit that this is, properly speaking, reasoning. (C.S.P.)

Rational [Lat. *ratio*, reason]: Ger. *vernünftig*, *rational*; Fr. *rationnel*; Ital. *razionale*. (1) Based on a REASON (q. v., in logic). Thus a conclusion is called rational.

(2) Connected with the exercise, or having the power, of REASONING (q. v.). Thus man is said to be a rational animal. (J.M.B.)

(3) In mathematics: expressible in the form of a fraction, i. e. equal to the exact quotient of the division of one whole number by another. In this sense, the word rational translates the Greek *ῥητός*. (C.S.P.)

Rational and Empirical Ego or Self: see SELF.

Rational Number: see RATIONAL (3), and cf. NUMBER.

Rationalism [Lat. *rationalis*, from *ratio*, reason]: Ger. *Rationalismus*; Fr. *rationalisme*; Ital. *razionalismo*. (1) The theory that everything in religion is to be rationally explained or else rejected. The application of ordinary logical standards and methods to dogma. Opposed particularly to supernaturalism. As Lecky (*Hist. of Rationalism*, i. 16) says, it signifies not 'any class of definite doctrines . . . but rather a certain cast of thought or bias of reasoning . . . which leads man on all occasions to subordinate dogmatic theology to the dictates of reason and of conscience.' In this sense it finds its best expression in the ENLIGHTENMENT (q. v.) of the 18th century.

(2) The theory that reason is an independent source of knowledge, distinct from sense-perception and having a higher authority. Opposed to SENSATIONALISM (q. v.). See REASON; and cf. INTELLECTUALISM, INTUITION, NOUS, and UNDERSTANDING.

(3) The theory that, in philosophy, certain elementary concepts are to be sought, and that all the remaining content of philosophy is to be derived, in a deductive way, from these fundamental notions. Opposed to EMPIRICISM (q. v.). In this sense it is used particularly of the method first explicitly stated by Descartes, developed by Spinoza and Leibnitz, formulated in detail by Wolff, and finally refuted by Kant.

The three senses are historically connected. The 18th century rationalism in morals and theology is derived from the insistence by Descartes upon method, and upon clearness and distinctness as criteria of truth. It is combined, however, with an empiricism which descends from Locke. The use of rational conceptions as the source from which other ideas are to be deductively derived is, of course, impossible unless there is some faculty through which these ideas are made known, as innate or *a priori* ideas, or through intuition, and so the second and third senses run together. None the less, rationalism in the second sense applies to a particular part of the content of philosophic doctrine, while in the third it expresses the *method* taken to be final in philosophy. The sketch that follows is confined to the third sense.

Descartes, seeking a criterion of certainty, hit upon the undoubted existence of inner

experience, and of certain ideas there found, which are *clear*, i.e. intuitively present and manifest, and *distinct*, precisely determined in themselves and in relation to other ideas. From these, by a mathematical method, various other truths may be derived; and with the system of such truths, original and derived, certain truth or science ends. The Port Royal *Logic* and the logical treatises of Geulinx attempted to expound the method with greater explicitness; but Spinoza completes it, first, by arranging the Cartesian philosophy, *de more geometrico*, and then by presenting his own philosophy in the *Ethica* as a series of axioms, definitions, propositions, &c. Leibnitz took up the idea with his usual energy and systematizing power, and advanced the idea of a universal logic and language which should be to philosophy what his calculus was to physics. He analyses all the conceptions involved more definitely; brings out the *a priori* character, the necessity and universality of all the primary notions; sets up as their criterion the principle of contradiction or impossibility of the opposite; and carries further the criterion of distinctness, making it to be that which is distinguished in itself from all other notions, and of 'adequate'—that which is clear down to its last constituent element and their relations to one another. Wolff systematized these conceptions of Leibnitz and combined them with an academic exposition of all the branches of philosophy.

Kant, awakened from his 'dogmatic slumber' in the rationalistic school by his acquaintance with Hume's sceptical attack upon causality and the principle of necessary connection, finally turns against rationalism as a method. He shows (a) that its identification with mathematical method is false, since the latter proceeds not by *analysis* of concepts, but by *construction* of space and time elements; (b) that from concepts only that can be deduced which has been previously put in them, and that hence the method is tautological or 'analytic' merely; (c) that to be a source of new truth, or synthetic, rational concepts must be applied to material of sense, gained in experience; (d) that when they are used as if they were themselves synthetic, certain fundamental antinomies, or mutually self-contradictory propositions, arise. Kant still endeavours to combine the truth of rationalism with that of empiricism; these necessary concepts *exist* independently of experience, but are *valid* only when used in reference to experience. Although the rationalistic method

is still incidentally used (even by those who claim to belong to the school of 'experience,' as by Spencer in his *UNIVERSAL POSTULATE*, q. v.), Kant gave it its death-blow as *the* method of philosophy. Hegel revived rationalism in a transformed sense, not applying to one factor or phase of knowledge, opposed to experience, but the construction of experience itself as a system of reason. (J.D.)

Rationalism (in aesthetics). A term applied to theories or tendencies in aesthetics which seek to explain aesthetic value by principles of an essentially logical nature, i.e. principles which relate properly to the work of the reason, such as unity, perfection (in the sense of conformity to an objective end), correctness, &c.

It is abstract **FORMALISM** (q. v.), and is opposed to **SENSUALISM** (q. v.). It differs from **INTELLECTUALISM** (q. v.) in that it relates rather to processes than to content. See also **PERFECTION**.

Literature: MARSHALL, Pain, Pleasure, and Aesthetics (1894), 120 ff.; HARTMANN, Aesthetik, I. Th. I, B. I. iii. 1 (1894). (J.H.T.)

Rationalism (in theology). (1) The doctrine which teaches, in opposition to mysticism, that the organ of religious knowledge is ratiocination rather than intuition.

(2) The claim that human reason is competent to discover and define religious truth without supernatural aid or divine revelation. Cf. **RATIONALISM** (1).

Rationalism versus mysticism has constituted an issue in all religious thought. Rationalism *versus* supernaturalism not only denies the supernatural in general, but specially the supernatural origin of Christianity and the claim of the Scriptures to be a divine revelation. It repudiates external authority and tends to combine a theory of naturalistic development with the claim that all religious truth is discernible by the unaided powers of reason.

Literature: LECKY, Hist. of Rationalism (London, 1865); CAIRNS, Unbelief in the Eighteenth Century (1881); STÜNDLIN, Gesch. d. Rationalismus u. Supernaturalismus (1826); AMAND SAINTES, Histoire crit. du Rationalisme en Allemagne (1841); THOLUCK, Gesch. des Rationalismus (1865). (A.T.O.)

Ravaisson (-Mollien), Jean Gaspard Félix. (1813-1900.) Born at Namur, and studied at the Collège Rollin and under Schelling at Munich. He became professor of philosophy at Rennes in 1838, and later held for many years the government position of

inspector of higher education. He belonged to the French idealistic school.

Ray of Direction: Ger. *Richtungsstrahl*; Fr. *rayon de direction*; Ital. *raggio di direzione*. The parts of the LINE OF DIRECTION (q. v.) that lie before the cornea and behind the lens, forming a portion of the path of what Helmholtz calls the 'ray of direction.'

The course of the ray and line may vary within the space bounded by the front surface of the cornea and the back surface of the lens. See LINE OF SIGHT.

Literature: HELMHOLTZ, *Physiol. Optik* (2nd ed.), 91. (C.L.F.)

Raymond of Sabunde. Died 1432. Born in Barcelona, Spain. He lived as philosopher, physician, and professor of theology in Toulouse, where he died.

Reacter: see REAGENT (2), and SUBJECT (of experiment). Not recommended. (J.M.B.)

Reaction [Lat. *reactio*, *re* + *actio*, action]: Ger. *Reaktion*; Fr. *réaction*; Ital. *reazione*. Response of a regular sort to stimulation.

Applied equally to low organisms which give reactions to light, &c., and to the highest; as vaso-motor reactions, reflex reactions, &c. The term is also sometimes used of the response of consciousness, notably of the attention. (J.M.B.)

Reaction (in physics): see ACTION AND REACTION.

Reaction Key: see LABORATORY AND APPARATUS, III, C, (1).

Reaction Time: Ger. *Reaktionszeit*; Fr. *temps de réaction*; Ital. *tempo di reazione*. The interval elapsing between stimulation and REACTION (q. v.). (H.C.W.—J.M.B.)

The term may be used to include all responses to stimuli, whether purely reflex or voluntary, and whether simple and definite or more or less complicated. Thus the time of the eye-wink reflex is included, as well as the time elapsing between a spoken word, giving rise to an association train, and some prearranged motor response following the completion of the association.

Reaction time is made up of three elements or periods: (1) the time required to overcome the inertia of the sense organ and transmit the impulse therefrom to the centre; (2) the time occupied by the central process or processes; and (3) the time required to transmit the outgoing impulse from the centre to the motor organ and overcome the inertia of the latter. (1) and (2) constitute the so-called 'physiological' time. The transmission time may be approximately estimated; the rate of

propagation of the nerve impulse, measured by electric stimulation of isolated nerve-fibres, is between thirty and forty metres per second. To this must be added the time spent in overcoming the inertia of sensory and motor end-organs, to obtain the entire physiological time. Deducting this from the total reaction time, we get the central time, which some regard as equivalent to the duration of the mental process when the higher centres are involved.

Simple reaction time. Investigations upon reaction time from the psychological standpoint are generally concerned with impulses passing through the higher or cerebral centres. In the simplest case the process is made as automatic as possible. A certain expected stimulus is suddenly 'released,' or brought to bear on the appropriate sense organ, and a prearranged response is made by the reagent as quickly as possible thereafter. The act thus approximates a cerebral reflex. The duration of the entire process, from release of stimulus to execution of movement, is termed the *simple reaction time*. The length of this period differs considerably according to the sense organ affected; for auditory stimuli it is from 120 to 230 σ ($\sigma = .001$ second), for visual from 170 to 290 σ , for pressure about the same as for auditory; the variability of a series taken under constant conditions is about one-tenth of the time. Practice results in a reduction of the time to the neighbourhood of the lower figures mentioned, but considerable difference is found between individuals. Ludwig Lange (*Philos. Stud.*, iv. 479 ff.) found that the time was about 110 σ longer when the attention was directed to the stimulus ('sensory reaction') than when it was directed to the movement of response ('motor or muscular reaction'). Wundt holds that the former includes perception, while the latter is a cerebral reflex (*Physiol. Psychol.*, 4th ed., ii. 309). Baldwin, Flournoy, and others found that the relative length of sensory and motor reactions varies with the individual, the sensory being the shorter in some cases; they hold that these differences indicate habitual attitudes or reaction types, consonant with the mental types of the reagents—what is called, as proposed by Baldwin, the type theory. Cf. TYPE (mental).

The time also varies with the intensity of the stimulus, the degree of attention and fatigue, &c. With stimuli of very small intensity the time is lengthened; the same effect

is observed where several stimuli of different intensity are used, the subject not knowing which to expect; in general, the time varies inversely with the subject's foreknowledge of the conditions. A high degree of attention shortens the time, as when a preliminary signal warns the subject when to expect the stimulus. Mental fatigue lengthens the time; distracting influences have the same effect, e. g. a continuous sound during a visual series. When the attention is strongly exerted, especially in motor reactions, cases of ANTICIPATION (q. v., 2) are liable to occur; i. e. the subject may react before the stimulus is given, either upon some other stimulus, such as the preliminary signal, or by impulse, from sheer inability to inhibit the reaction.

Pressure reactions have been made upon a group of subjects acting in conjunction. The subjects hold hands; the first one presses the hand of the second, the second that of the third, and so on, till the circuit is completed, the first subject noting the time. This is called a chain reaction. The simple reaction time is found by dividing the entire time by the number of subjects, with proper corrections for the beginning and end of the series. Few investigations of reaction times have been made outside of the senses of sight, hearing, and touch.

Complex reaction times. Acts of recognition, discrimination, choice, association, &c., may be included in the reaction, and their duration approximately determined.

(1) Recognition and discrimination. If two or more stimuli differing (e. g.) in intensity are used, the subject to react when he has determined which one is present, the process is called a *discrimination reaction*. If the stimuli are chosen from a large series, each member of which has a well-known name (e. g. the colours, numerals, letters), the subject to react when he has determined what is present, it is called a *recognition reaction*. The discrimination time or recognition time, as the case may be, is found by subtracting the subject's previously determined simple reaction time from the total duration of the reaction; it is about 50 σ for the simplest case. The discrimination time for auditory stimuli of different intensities was investigated by Tischer (*Philos. Stud.*, i. 495 ff.); the time lengthens as the number of intensities to be discriminated increases. In vision, many forms of discrimination and recognition have been investigated, such as discrimination of black and white (Wundt), colour recognition

(Titchener), letter and word recognition (Cattell), recognition of numerals (Friedrich), &c. (see Wundt, *Physiol. Psychol.*, ii. 368 ff., and references there given). The results indicate that recognition is a shorter process than discrimination; e. g. recognition of colours requires less time than discrimination of two shades in the black-white series. Cattell found that the recognition of familiar objects (represented in pictures) required slightly less time than the recognition of letters of the alphabet or short words, the latter processes being about equal in duration. When the reaction involved naming the given stimulus the order was different: for short words the time was shortest, for letters next, for familiar objects, longest (Cattell, *Philos. Stud.*, ii. 635, iii. 452). Using numerals instead of letters, the time increases with the number of figures, especially with more than two or three.

(2) Choice. Choice-reaction involves a different mode of response for each kind of stimulus given. The naming of letters or objects, mentioned above, involves a reflex choice; but in many cases the mode of response as prearranged is purely arbitrary, e. g. reaction with a different finger for each kind of stimulus (Merkel, *Philos. Stud.*, ii. 73 ff.; Münsterberg, *Beitr. z. exper. Psychol.*, i. 69 ff.). The reaction time here is longer than for recognition or discrimination, and increases with the number of kinds of reactions involved. The particular mode of reaction, the individuality of the subject, and the general conditions of the problem introduce such variations, however, that the actual times found probably apply to the specific investigations only. Even with the same subject, the variable factors are so numerous and important that it is difficult to obtain series whose mean variation is small enough to allow the results to pass unchallenged. The same remark applies to complex reactions generally.

(3) Association. The time required for associating an answer with a given question has been investigated. Münsterberg (op. cit., i. 94 ff.) found that a question admitting but a single answer (e. g. 'On what river is Cologne?') was answered more quickly than one which presented several alternatives (e. g. to name a German wine). The actual association time is difficult to determine, however, on account of the uncertainty as to when the purport of the question comes to be understood. Less open to doubt are investigations in which a word or picture is shown, or a word

REACTION TIME

repeated, with which the subject is to associate an idea, either at random ('free, or unlimited association') or according to pre-arranged conditions ('limited association'). For limited association may be selected the relation of genus to species, cause to effect, part to whole, or others. Free associations, when obtained, may be classified into logical, objective, and verbal, with their sub-groups, and the relative time of these categories compared (Cattell, *Mind*, xii. 68 ff.; Münsterberg, loc. cit.). Münsterberg finds that the reaction time for free association is, on the average, less than for limited, but greater than for questions admitting of a single answer. The number of subjects thus far tested is scarcely large enough to warrant generalization, especially with regard to the different classes of association.

(4) Other applications. The reaction-time method may be used to determine the character of a mental process. Thus the reaction time of a group of marks or dots varies with the size of the group and the manner of grouping; within certain limits the process is simple perception, as shown by its short duration; where the time is longer the act becomes one of counting (Warren, *Psychol. Rev.*, iv. 569).

The PERSONAL EQUATION (q. v.) observed in astronomical and similar reactions arises from the attempt to react simultaneously with an objective occurrence (such as the contact of a star with a meridian line), where the instant of occurrence can be definitely anticipated on account of the antecedents.

Comparative and abnormal reaction times. The effects of mental and physical fatigue, of the use of drugs, &c., have been measured by comparing the reaction times under these conditions with those of the same individual in the normal state (see PSYCHIC EFFECT OF DRUGS). The reaction times of nervous persons and criminals have been obtained and compared with the average of normal individuals. Differences of sex and race have been investigated, and some attempt has been made to find the reaction times of animals.

Method and apparatus. The length of the reaction time is measured either chronometrically or graphically. In the former method the usual instrument is the Hipp chronoscope, which allows readings to be made to the one-thousandth of a second. For chain reactions a stop-watch gives sufficiently accurate measurements if the number of subjects is large. The graphic measure of

time is by means of a chronograph; a record is made on a revolving drum of the vibrations of a tuning-fork during the interval to be measured. See LABORATORY AND APPARATUS, III, C.

The beginning and end of the reaction are usually determined by means of an electric current. The stimulus is arranged so as to make (or break) a circuit which controls the time-measuring instrument, while the reaction movement serves to break (or make) it. The stimulus release is effected in visual reactions by means of a screen with an aperture; the screen swings or falls, revealing the stimulus behind it, and the circuit is made (or broken) simultaneously with the appearance. For auditory stimuli the blow which causes the sound makes the circuit also. The most common form of motor response is the act of pressing a telegrapher's key with the finger or hand. Other forms are with the lip key, tongue key, and mouth or voice key. These are used in complex reactions where a variety of responses is desired; the speaking of different words fulfils this condition. A multiple key for reaction with different fingers is used in choice-reactions. For description of various forms of stimulus releasers and reaction keys see LABORATORY AND APPARATUS, II, C.

Reactive Consciousness: see (reflex) ATTENTION.

Reagent [Lat. *re* + *agere*, to act, lead, do]: Ger. *Reagens*, *Zersetzungs- oder Erkennungsmittel*; Fr. *réactif*; Ital. *reattivo*. (1) In chemistry: any substance used to cause a chemical reaction. Anything used to detect, by means of such reaction, the presence of other substances. Such are Millon's reagent, as test for proteids; Nessler's reagent, used to detect the presence of ammonia; staining reagents.

(2) In psychology: the subject in a psychological experiment. See SUBJECT (of experiment).

(3) In physiology: any stimulus which causes a physiological REACTION (q. v.).

(C.F.H.—J.M.B.)

Real and Reality, Actual, Being, Existence: for derivations and foreign equivalents see the separate headings below.

I. (1) (a) *Real* [Lat. *realis*, from *res*, thing]: Ger. *real*; Fr. *réel*; Ital. *reale*. Universally employed to denote that a thing is both (a) an existent (see below, IV) and (b) true, though it is also used with various other implications, according to the various definitions of reality adopted or proposed by various philosophers, which are, however, never definitions, but only descriptions of properties supposed to belong necessarily to what is real. Reality is thus properly opposed both (a) to things in the conception of which existence is included but which do not truly exist, (b) to subjects of non-existential propositions, and (c) to what is neither true nor false.

(b) *Real* is very commonly used with a negative implication, as contradictory of the

self-contradictory conception, 'that of which it is true both that it does and that it does not exist.' This contradictory conception is very common under various names; and in connection with it things may be said to be more or less real, according to the proportion of truth in the assertions that they do or do not exist. (G.E.M.)

By 'true' above is meant determined (see *Existence*, below, IV), but determined absolutely, that is, in a sphere or universe, existence in which is the final determination of thought (or of that function by which final determination is possible). TRUTH (q. v.) is the limiting notion of determinateness; and for this reason the real cannot be defined, for it is itself the method of determination or definition by which being (see below, III) becomes real; yet its meaning in the genesis of experience can be psychologically traced.

(2) *Reality*: Ger. *Realität*; Fr. *réalité*; Ital. *realità*. Determined being (see below, III), but not being determined as 'what.' For to determine being as 'what' is to circumscribe and relate it in a universe of existence which denies its universality.

Psychologically, reality is a NOTION but not a CONCEPT (see those terms): we mean something by reality, but we do not think something by it. It is just the fact of determination in experience abstracted from all forms of real determination. It is the mind's recognition of every possible thing as a possible determination or existence; and is thus contrasted with being, which is reality from which determination is in turn abstracted. Reality is that for which all actual coefficients of belief stand in common, apart from the existences for which they respectively stand. (J.M.B.)

II. *Actual* [Lat. *actum*, something done, through Fr.]: Ger. *wirklich*; Fr. *actuel*; Ital. *attuale*. Actual, like real, implies both truth and existence; but, in accordance with its original opposition to 'potential' or 'implicit,' it throws more emphasis on existence, and particularly present and presented existence (cf. FACT). In modern philosophy it is often contrasted with reality, as denoting the degree and kind of reality supposed to belong to the objects of experience. As denoting the degree, it always has a depreciatory sense; things are 'merely,' i.e. relatively, actual. But as denoting the kind, i.e. immediacy or direct presentation, its claim is high. See ACTUALITY. (G.E.M.)

III. BEING (q. v., 1, also for derivation and

equivalents) is a simple term, and therefore strictly undefinable. It denotes 'givenness,' 'presence,' the ultimate 'datum' or 'position.' (J.M.B.)

It is an absolutely universal term; i.e. not only 'realities' and 'actualities,' but propositions, whether true or false, and any terms that can be used in a proposition, have being or are entities. (G.E.M.)

IV. EXISTENCE (q.v. for derivation): Ger. *Dasein*; Fr. *existence*; Ital. *esistenza*. Like being, a simple term and strictly undefinable. It denotes determinate being, or 'givenness,' in a context by which its meaning is largely determined (note the *da* of *Dasein*). So we have universes or spheres of existence, all of which share being. The scholastics used various phrases for these different spheres of existence: *in re*, *in intellectu*, *in esse*, *in posse*, &c. For other meanings see BEING (2, 3). (J.M.B.)

The second sense of reality is fully developed in Plato, who calls 'realities' *ὄντως* or *ἀληθῶς ὄντα*, as opposed to the self-contradictory existences, which he calls *γινόμενα*; but his conception of *γινόμενα* does not fully correspond to actuality, though it is applied to the same things, i.e. the objects of experience. Plato does not distinguish being from reality, but 'defines' his *ὄντως ὄντα* chiefly by the characteristics which belong to mere beings. Aristotle's term for 'reality' in sense (2) is *πρώτη οὐσία*, which he 'defines' in two ways, either as *ἐντελέχεια* or *ἐνέργεια*. Since *ἐντελέχεια* denotes the combination of form and matter, or *ἐνέργεια* and *δύναμις*, and since matter and *δύναμις* involve incomplete reality, *ἐντελέχεια* corresponds more nearly to 'actuality'; and since things are more or less real according as they are more or less *ἐνεργεῖα* (*actu*, from which our 'actuality' is derived), while the one absolute reality (*πρώτως ὄν*) has no *δύναμις*, *ἐνέργεια* would seem more nearly equivalent to reality: yet *πρώτη οὐσία* is most frequently defined as *ἐντελέχεια*. Aristotle regards mere beings as 'logical entities' (*λόγῳ χωριστά*), thus starting the conception of them as mental or verbal existents, which has been prevalent ever since: the mediaeval controversy between 'Realists' and 'Nominalists' (see REALISM, 1) is in the main a controversy between the Platonic and Aristotelian views on this point. There is no separate Greek term for existence: the use of the term seems to have grown up in the middle ages along with that of essence, this pair gradually taking the place of the less abstract Aristotelian matter and form (*ὑλη* and *εἶδος*). The modern contrast between

'actuality' and 'reality' dates only from Kant's emphatic opposition of experience to things in themselves, and is mainly used by philosophers who have been influenced by his doctrines: both before and since his time 'real' in sense (2) is chiefly contrasted with 'ideal' or 'phenomenal.' (G.E.M.)

Real Idealism or Ideal Realism: Ger. *Real-Idealismus*, *Ideal-Realismus*; Fr. *réal-idéalisme*, *idéel-réalisme*; Ital. *realismo idealistico*. The theory which holds IDEALISM (q.v., 2) in epistemology, i.e. the reduction of the real to elements which are ideal—and with it REALISM (q.v., 2) in metaphysics, i.e. the embodiment of what is ideal in the conception of the real. In short, it is the identification of real and ideal. Cf. IDENTITY PHILOSOPHY.

So, with differences of method and terminology, Leibnitz, Lotze, Fichte, Schelling, &c. See citations in Eisler, *Wörterb. d. philos. Begriffe*, 'Ideal-Realismus.' (J.M.B.)

Realism: Ger. *Realismus*; Fr. *réalisme*; Ital. *realismo*. The term has two important meanings in philosophy, wholly distinct from each other. (1) In one, and the older sense, it is a logical-metaphysical theory, having to do with the reality of universals in themselves, and their relation to individuals. Its classic expression is that universals are real *ante res* (in God's mind), *in rebus* (in nature), and *post res* (in their historical apprehension by human minds). However, it has even more extreme forms.

(2) In the more modern and epistemological-metaphysical theory, it is the doctrine that reality exists apart from its presentation to, or conception by, consciousness; or that if, as matter of fact, it has no separate existence to the divine consciousness, it is not in virtue of anything appertaining to consciousness as such.

It is opposed to IDEALISM (q.v. for history of this meaning). Historically, it has been found in many forms and under many names. See NATURAL REALISM. Kant terms his philosophy *empirical realism*, meaning that it holds to an existence of things in space independent of our particular states of consciousness, opposing it to *transcendental realism*, which asserts that time and space are something in themselves independent of our sensibility (*Crit. of Pure Reason*, 320-6, Müller's trans.). Spencer calls his philosophy *transfigured realism*, which means that 'some objective existence, manifested under some conditions,' separate from and independent of

subjective existence, is the final necessity of thought, and yet that the perceptions and objects in consciousness are not the reality, and do not resemble, but only symbolize it. At the same time he marks this off from 'hypothetical realism,' because that only asserts the existence of this real as an inference, not as a 'fact' (*Psychol.*, ii. chap. xix). Lewes calls his theory *reasoned realism*, which he distinguishes not only from crude or natural realism, but also from the transfigured. It asserts that the reality of an external existence, a not-self, is given in feeling, and indissolubly woven into consciousness. Here realism seems to mean not externality to consciousness, but externality to the subject, or ego, in consciousness (*Problems of Life and Mind*, 176-95). See also REAL IDEALISM (or Ideal Realism).

We shall now take up realism in the first sense. In one aspect the problem goes back to Socrates, who asserted that the object of knowledge (and hence the true, the certain, the real) was the universal, endeavouring in this way to overcome the subjectivism of the Sophists. In Plato, the universals appear as the ideas and the true or absolute beings; and an exposition of the method of arriving at them, of their nature and interrelations, and their connection with the various forms of reality and experience constitutes the chief object of his philosophy. It was long fashionable to regard him as an extreme realist in the mediaeval sense, that is, as asserting the subsistence of universals by themselves, independent of any relation to individuals—*ante res*. Aristotle is largely responsible for this interpretation, since he continually polemicizes against the Platonic separation of the ideas; he is the authority with the Scholastics. But, in the first place, the ultimate reality with Aristotle, the pure form, has the same transcendence which he attributes to the Platonic idea, so far as existence is concerned. It is, at bottom, the lack of *dynamic* connection with the world which Aristotle, whether rightly or wrongly, criticizes in Plato—a lack which he attempts to fill by his theory of the form as the end, which matter as the potential always attempts to realize, and hence moves towards. But, in the second place, and more significantly, the whole mediaeval and modern conception of realism is foreign to the interests of Greek philosophy, both Platonic and Aristotelian. Plato and Aristotle are interested in showing that the real is universal, and under what conditions it becomes or is indi-

vidual; but the interest in the obverse question, the reality of the universal and of the individual, is one which depends upon the whole intervening period, indicating indeed that the starting-point has been reversed. It could not arise until the psychological movement had gone far enough to correlate the universal and subjective thought.

This is not to say, of course, that mediaeval thought did not naturally and inevitably identify its own problems with those of Greek thought, and even cast them in the terms of that thought. Neo-Platonism, with its express derivation of the hierarchy of successive forms of thought and being from the more universal as the more real, was the immediate cause of this identification, so that realism is the first to make its appearance, which it does in full-fledged form in SCOTUS ERIGENA (q. v., and also SCHOLASTICISM). It is a matter of moment that realism is the doctrine of those who are especially interested in philosophic content, while nominalism appears, at first, rather as a merely formal and logical doctrine. As such, it is a passage in the translation by Boethius of Porphyry's introduction to the *Categories* of Aristotle which started the discussion—a treatise, it must be remembered, which at this period was known only quite apart from the metaphysics and physics of Aristotle. The passage raised the problem of genera and species, (1) as to whether they subsist in themselves or only in the mind; (2) whether, if subsistent, they are corporeal or incorporeal; and (3) whether separated from sensible things, or placed in them. Roscelin appears as an extreme nominalist, holding that the universals are only abstractions from particular things (are *post res*), and in themselves are only words (*voces*) or names (*nomina*). William of Champeaux asserted realism in its most extreme form. Only genera are substances; individuals are only their attributes; manhood is essential, Socrates accidental. Moreover, *every* universal is real; whiteness would be real even if there were no white thing. These extreme views obviously demanded some attempt at mediation. This was supplied by Abelard. He held that a universal, even as a name, is yet more than a name; it is a predicate, or *sermo*. This is reached only by conception, which, comparing individual things, reaches that which 'naturally' is a predicate. So far Abelard would be classed as a conceptualist. But he goes on to develop the idea of a *natural* predicate. Since universals are the instruments of all know-

ledge, there must be something in the nature of things which is their basis; namely, *similarity* in the things themselves. Moreover, this similarity is due to the fact that the universals are the modes or archetypes in God's mind, according to which he creates particular things—a view emphasized also by Bernard of Chartres and by Gilbert of Poitiers. The latter, however, leans more to realism in holding that while these concepts or forms of the divine mind become *universals* only in things, they are really in things (*in re*), and not merely factors of likeness to be apprehended (collected) in turn by the human mind. Here the discussion practically rests for the time; justice seems to be done to all the elements involved, and the doctrine being accepted by Alexander, and by Thomists and Scotists alike, in the second period of *scholasticism* the discussion passes into the background.

It did not wholly rest, however; those who continued the tradition of the merely formal logic, occupying themselves with *propositions* rather than with *judgments*, continued the old nominalistic terminology. What was termed 'modern logic,' depending upon some Byzantine compendiums, was developed. It involved the theory of the syllogism, in its different figures, in relation to component propositions, and the elements of these propositions—very much, indeed, what passes in the logic of the syllogism to-day. This was elaborated by Peter of Spain. According to it the predicate (which of course is the universal) is only a sign. With Peter and his school the doctrine remained a harmless detail of formal logic. But William of Occam develops it and combines it with a metaphysical theory of the nature of (distinct) individuals, which had come to the front. Realism, even in its moderate forms, seemed to find the essential reality in the generic, if not in or before things literally, at least as 'thoughts' in the mind of God. As long as the object of chief interest was the universe as a whole, and the Church and state as wholes, the doctrine naturally commended itself. But with the growth of consciousness of particular individuality (*haecceitas*, this special uniquely distinguished individual) the doctrine presented grave difficulties. It seemed to lead to a most thorough-going predeterminism, according to which everything in or about the individual is eternally foreordained in the thought of God. Duns Scotus had insisted upon the primal character of individuality

(*haecceitas*), but had still regarded it as form, as the generic substantialized. But William of Occam recognized that this view still left the individual in an ambiguous position; logically, at least, the individual still appears as subordinate to the universal. Hence with him nominalism is not, as with the earlier writers, a merely negative assertion of the verbal or conceptual character of ideas; it is the positive assertion that specific individualities, differentiated in themselves, are the real; and that universals are discursively gathered from our original intuitive knowledge of these individuals. (In this direct apprehension, William includes both sensation, knowledge of our own internal states—more certain than sense-knowledge—and the intellectual intuition of the essence of the soul.) Just because Occam's theory was congruent with the rising practical individualism of the day (in politics and religion), because it agreed with the rising physical science—emphasizing the knowledge of particular phenomena instead of abstract and occult essences—and because it fell in with the growing psychological tendency to study the natural history of knowledge, and not simply its logical forms, nominalism became as triumphant at this period as realism had been at the earlier.

With the breaking up of mediaevalism, the discussion passed over into psychology. The interest was in abstract and general ideas, or abstraction and generalization, rather than in universals as such. Accordingly, our statement ends here—save to remark that, since modern science deals so evidently with universals, with laws, the problem of whether or no any objective reality is to be conceded to these universals, and if so, in what way, is coming to the front again in modern logic; and thus in so far the old discussion is again raised. In accordance with the spirit of an early remark, we may note from another point of view the difference of the ancient from the mediaeval realism. The ancient deals with the universal as the *essence*, the constitutive factor, whether before or in individuals; the mediaeval deals with it as the *generic*. Hence to an ancient to have identified the universal with a mere concept would have been impossible, save to assert absolute scepticism; with the moderns it was a natural outlet. With recent thought, the universal becomes law, or method. Cf. LATIN AND SCHOLASTIC TERMINOLOGY.

Literature, to (1): PRANTL, *Gesch. d. Logik*, is the authority for the details of practically all

writers. Cf. the titles cited under SCHOLASTICISM. The following are important: JOHN OF SALISBURY, *Metalogicus*, ii. chap. xvii ff. (gives a summary of views of previous writers, all the more valuable because he confesses himself unable to take any position); BARACH, *Zur Gesch. d. Nominalismus vor Rocellin*; LÖWE, *Der Kampf zwischen Nominalismus u. Realismus*; EXNER, *Nominalismus u. Realismus*; KÖHLER, *Realismus u. Nominalismus*. (J.D.)

To (2): (natural realism) works of REID, TH. BROWN, D. STEWART, McCOSH (esp. *Hist. of the Scottish Philos.*); (French realism) works of JOUFFROY, BIRAN, COUSIN, JANET. See also the writers cited above and the histories of philosophy; the literature of EPISTEMOLOGY, and PHILOSOPHY, and BIBLIOG. B, 2, d. (J.M.B.)

Realism (in aesthetics). Primarily, a style or mode of artistic treatment which represents its objects as they 'really' or actually are, as opposed to IDEALISM (q. v.), which selects and modifies.

Practically, the artist must in any case select at least his object and point of view, hence the term has been determined largely by antithesis to the various meanings of idealism, giving three distinct species:—

(1) A treatment which emphasizes individuality, as contrasted with an idealism which emphasizes the TYPE (q. v.).

(2) A treatment which brings out especially the strong, harsh, and even ugly aspects of reality or life, as contrasted with an idealism which seeks the harmonious.

(3) A treatment which professes to make no selection on the ground of intrinsic aesthetic value, and to attempt no intensification of interesting features, but to reproduce all aspects of reality and all detail without discrimination or modification, contrasted with an idealism which selects and modifies according to the artist's aesthetic interest.

Owing to the confusion involved in these different antitheses, Volkelt suggests as a more useful pair of antitheses: (a) intensifying *versus* matter-of-fact (*potenzierender Stil und Thatsachenstil*); (b) individualizing *versus* typicizing (*typisierender*).

The various meanings of the term have grown out of the varying modes of art-consciousness of different periods. Cf. BEAUTY, ART, and CHARACTERISTIC. (J.H.T.)

In contrast with NATURALISM (q. v., in aesthetics), realism portrays what is essential to the individual or illustrates the concept of

the individual; while naturalism fails to distinguish between what is essential and what accidental to the individual. Idealism depicts, on the other hand, what is general, and essentially general (cf. Alt, *Syst. d. Künste*). (K.G.)

Literature: VOLKELT, *Aesth. Zeitfragen* (1895), chap. iv; FECHNER, *Vorschule d. Aesth.* (1876), xxii, xxvii; SYMONDS, *Essays Spec. and Sugg.*, 117 ff.; LA FARGE, *Considerations on Painting* (1896), chaps. ii, iii. (J.H.T.)

Reality: see REAL.

Reality Feeling and **Realizing Sense**: Ger. *Realitätsgefühl*; Fr. *sentiment de réalité*; Ital. *sentimento della realtà*. Reality feeling is 'the feeling which means, as the child afterwards learns, that an object is really there . . . contrasted with belief . . . which indicates the amount of assurance we have at the time that an object is there' (Baldwin, *Handb. of Psychol., Feeling and Will*, chap. iii, 'Interest, Reality Feeling, and Belief,' where the term was originally suggested).

The disturbance of reality feeling gives 'unreality feeling,' a certain distrust of experience leading to trial and error and the gradual grounding of things believed. Cf. BELIEF.

Realizing sense is a popular term for reality feeling, either with or without the intellectual conviction of explicit belief.

Literature: titles given under BELIEF, especially the books of JAMES, VORBRODT, STOUT, BALDWIN. (J.M.B.)

Realization: see SELF-REALIZATION, and cf. REALITY FEELING.

Realizing Sense: see REALITY FEELING.

Reals: Ger. *Realen*; Fr. *réels*, (*les*) *êtres*; Ital. *reali*. A term used by Herbart to name the (pluralistic) ultimate beings.

Each is a monad, and absolute in itself. A plurality of qualities in a being means a relative element. Hence each real is perfectly simple in quality. This quality is undefinable. These reals act upon one another by way of disturbance, and react to disturbance in the way of self-preservation. Presentations (*Vorstellungen*) are self-preserved reactions on the part of that real called mind. (J.D.)

Reason [Lat. *ratio*, through Fr.]: Ger. (1) *Verstand*, (2, 3) *Vernunft*; Fr. *raison*; Ital. *ragione*. (1) That faculty and process (*νοῦς*, *διάνοια*, *ratio*) of mind which consists in the drawing of inferences. See INFERENCE, and THOUGHT, and cf. REASONING.

It is in this wide sense that man is defined as a 'rational animal.' The term thus came to be applied to a special 'faculty' by means of which man was supposed to

draw inferences; but it has always tended to be restricted to that part of such supposed faculty by means of which he drew valid inferences from true premises. In this sense it is opposed to INSTINCT (q. v.).

(2) From the restriction of 'reason' to the valid inference of true conclusions was derived a further use, in which it denotes the supposed faculty by which we apprehend intuitively, or without inferring, truths which stand to particular judgments about what exists at this or that time or place, in the relation of a REASON (q. v., in logic) to its consequence.

In this sense reason is opposed to sensation, perception, and imagination, and also, especially where the truths in question are ethical principles, to feeling and desire.

By the term PRACTICAL REASON (q. v.) is meant either a special faculty or a part of the general faculty of reason, which is supposed both (a) to apprehend the reason why particular actions ought to be performed, i.e. either the principle from which their rightness follows, or the fact that they are means to an end, and (b) to cause the performance of such actions. [The Aristotelian sense is that of 'reason directed towards the attainment of an end.'—A.S.P.P. See PRACTICAL REASON (1).]

(3) By a still further distinction reason is restricted to the faculty by which we are supposed to apprehend the real nature of the world as a whole, or the one ultimate reason of all consequences. The term is still applied to the mind, in so far as it is supposed to exercise this function, although the doctrine of particular faculties has been generally given up. Cf. UNDERSTANDING AND REASON.

The word λόγος is vaguely used to cover all senses of reason, but is less frequently used to denote the psychological fact of belief. In Aristotle it is mainly restricted to mean the definition of a thing, including the verbal description of that 'formal cause,' which Plato and Aristotle alike supposed to be one of the reasons of a thing's existence. Aristotle uses the word ἀρχή to cover reason in the proper sense; and he distinguishes as a less proper use of the term that in which it stands for any true proposition from which another is inferred actually (a), a distinction which gave rise to the scholastic distinction between *ratio cognoscendi* and *ratio essendi*, of which also it is recognized that the latter is more properly called reason. These two terms correspond respectively to consequence and reason, in their proper sense, except that the former sometimes includes the cause of our knowing

a truth, and the latter the cause of a thing's existence. Leibnitz uses the term SUFFICIENT REASON (q. v.) to denote a kind of 'final cause,' which he supposes to be the only true cause of every event. See CAUSE.

The word νοῦς covers vaguely all meanings of reason [and is especially used in distinction from understanding, ἐπιστήμη or διάνοια — A.S.P.P.]; but it tends to be confined by Plato and Aristotle to the faculty by which we apprehend true reasons without inference, and to be distinguished from other generally synonymous words, such as διάνοια, as denoting the faculty by which we apprehend the most ultimate truths. The Stoics, by personifying the λόγος, of which Heraclitus had spoken as the law of all changes in the universe, gave to this word much the same meaning as belonged to νοῦς in Plato and Aristotle.

The use of both words was continued by Philo, by the Christian Fathers, and by the Neo-Platonists, νοῦς being sometimes applied, as by Philo, to the human reason as a part of the one divine λόγος, and sometimes, e.g. by Valentine and Plotinus, to an entity conceived as superior to that which they denote by λόγος. It is from this use of λόγος, through its Latin equivalent, *ratio*, that our use of reason to denote a mental faculty is derived. The antithesis between reason and revelation, emphasized by Christian Apologists against the Gnostics and Neo-Platonists, prepared the way for the scholastic use of 'ratio' to denote our capacity for drawing valid inferences of which the results are not necessarily true—a use in which it was opposed to that 'faith' by which we were supposed to apprehend revealed truths. This use alone dominated mediaeval philosophy, culminating in the avowed doctrine that unorthodox deductions might be true *secundum rationem*, although in flat contradiction to what was true *secundum fidem*. After the Renaissance the vague use of reason to mean the faculty by which we apprehend abstract truths, with or without inference, again became prominent; and a more definite meaning was first brought into vogue by the distinction of Kant's between reason and understanding—a distinction also adopted by Hegel. (G.E.M.)

Reason (in logic): Ger. *Grund*; Fr. *raison*; Ital. *ragione*. One or more of the propositions from which another is validly inferred. See REASONING, and SUFFICIENT REASON. (J.M.B.)

Reason (in theology). The concrete intelligence of man as exercised in the discovery or apprehension of religious truth.

Reason in this sense includes intuition in so far as that function yields ideas and concepts. It is to be distinguished, however, from intuition regarded as a mere subjective sense. The great distinction in theology, however, is that which exists between reason and a faith resting on some objective or external authority. It is generally conceded that what is intrinsically irrational cannot be a legitimate object of faith.

Literature: see RATIONALISM, REVELATION, and SUPERNATURALISM. (A.T.O.)

Reason (sufficient): see SUFFICIENT REASON, and REASON (in logic).

Reasonable (1) and (2) **Unreasonable**: Ger. *vernünftig, unvernünftig*; Fr. *raisonnable, déraisonnable*; Ital. *ragionevole, irragionevole*. (1) Having, and (2) not having, what is considered adequate ground or justification. See REASON (in logic), and cf. RATIONAL.

The terms—notably unreasonable—are especially (though not exclusively) applied to actions or active decisions, attitudes, &c., having reference to the element of conation which enters into these. We say a conclusion or inference is illegitimate, wrong, or false, but the act based upon this conclusion we call ‘unreasonable.’ Moreover, there is a slight reproach attaching to a course that is unreasonable which does not attach to what is merely mistaken or ill-judged—a further indication that an element of conation is involved. (J.M.B.)

Reasoned Realism: see REALISM (2).

Reasoning: Ger. *Schliessen* (inference), *Denken* (thought); Fr. *raisonnement*; Ital. *ragionamento*. Thinking in logical form, correct or incorrect.

‘Direct’ reasoning or inference is the case in which the proof proceeds directly to the conclusion; an ‘indirect’ conclusion follows from the proof of something else (see PROOF). ‘Deceptive reasoning’ is reasoning which involves a logical fallacy. (J.M.B.)

Reasoning is a process in which the reasoner is conscious that a judgment, the conclusion, is determined by other judgment or judgments, the premises, according to a general habit of thought, which he may not be able precisely to formulate, but which he approves as conducive to true knowledge. By true knowledge he means, though he is not usually able to analyse his meaning, the ultimate knowledge in which he hopes that belief may ultimately rest, undisturbed by doubt, in regard to the particular subject to which his conclusion relates. Without this logical ap-

proval, the process, although it may be closely analogous to reasoning in other respects, lacks the essence of reasoning. Every reasoner, therefore, since he approves certain habits, and consequently methods, of reasoning, accepts a logical doctrine, called his *logica utens*. Reasoning does not begin until a judgment has been formed; for the antecedent cognitive operations are not subject to logical approval or disapproval, being subconscious, or not sufficiently near the surface of consciousness, and therefore uncontrollable. Reasoning, therefore, begins with premises which are adopted as representing percepts, or generalizations of such percepts. All the reasoner’s conclusions ought to refer solely to the percepts, or rather to propositions expressing facts of perception. But this is not to say that the general conceptions to which he attains have no value in themselves.

Reasoning is of three elementary kinds; but mixed reasonings are more common. These three kinds are *induction*, *deduction*, and *presumption* (for which the present writer proposes the name *abduction*).

Induction takes place when the reasoner already holds a theory more or less problematically (ranging from a pure interrogative apprehension to a strong leaning mixed with ever so little doubt); and having reflected that if that theory be true, then under certain conditions certain phenomena ought to appear (the stranger and less antecedently credible the better), proceeds to *experiment*, that is, to realize those conditions and watch for the predicted phenomena. Upon their appearance he accepts the theory with a modality which recognizes it provisionally as approximately true. The logical warrant for this is that this method persistently applied to the problem must in the long run produce a convergence (though irregular) to the truth; for the truth of a theory consists very largely in this, that every perceptual deduction from it is verified. It is of the essence of induction that the consequence of the theory should be drawn first in regard to the unknown, or virtually unknown, result of experiment; and that this should virtually be only ascertained afterward. For if we look over the phenomena to find agreements with the theory, it is a mere question of ingenuity and industry how many we shall find. Induction (at least, in its typical forms) contributes nothing to our knowledge except to tell us approximately how often, in the course of such experience as our experiments go towards constituting, a

given sort of event occurs. It thus simply evaluates an objective probability. Its validity does not depend upon the uniformity of nature, or anything of that kind. The uniformity of nature may tend to give the probability evaluated an extremely great or small value; but even if nature were not uniform, induction would be sure to find it out, *so long as inductive reasoning could be performed at all*. Of course a certain degree of special uniformity is requisite for that.

But all the above is at variance with the doctrines of almost all logicians; and, in particular, they commonly teach that the inductive conclusion approximates to the truth because of the uniformity of nature. They only contemplate as inductive reasoning cases in which, from finding that certain individuals of a class have certain characters, the reasoner concludes that every single individual of the class has the same character. According to the definition here given, that inference is not inductive, but is a mixture of deduction and presumption. Cf. INDUCTION, and PROBABLE INFERENCE.

On the methods of inductive reasoning see DIFFERENCE (method of), CONCOMITANCE (logical), AGREEMENT (method of), and Elimination under SCIENTIFIC METHOD. For Eliminative Reasoning (Ausschlussverfahren—Eisler) see SYLLOGISM.

Presumption, or, more precisely, *abduction* (which the present writer believes to have been what Aristotle's twenty-fifth chapter of the second *Prior Analytics* imperfectly described under the name of ἀναγωγή, until Apellicon substituted a single wrong word and thus disturbed the sense of the whole), furnishes the reasoner with the problematic theory which induction verifies. Upon finding himself confronted with a phenomenon unlike what he would have expected under the circumstances, he looks over its features and notices some remarkable character or relation among them, which he at once recognizes as being characteristic of some conception with which his mind is already stored, so that a theory is suggested which would *explain* (that is, render necessary) that which is surprising in the phenomena.

He therefore accepts that theory so far as to give it a high place in the list of theories of those phenomena which call for further examination. If this is all his conclusion amounts to, it may be asked: What need of reasoning was there? Is he not free to examine what theories he likes? The answer is that it is a question of economy. If he examines all the

foolish theories he might imagine, he never will (short of a miracle) light upon the true one. Indeed, even with the most rational procedure, he never would do so, were there not an affinity between his ideas and nature's ways. However, if there be any attainable truth, as he hopes, it is plain that the only way in which it is to be attained is by trying the hypotheses which seem reasonable and which lead to such consequences as are observed.

Presumption is the only kind of reasoning which supplies new ideas, the only kind which is, in this sense, synthetic. Induction is justified as a method which must in the long run lead up to the truth, and that, by gradual modification of the actual conclusion. There is no such warrant for presumption. The hypothesis which it problematically concludes is frequently utterly wrong itself, and even the method need not ever lead to the truth; for it may be that the features of the phenomena which it aims to explain have no rational explanation at all. Its only justification is that its method is the only way in which there can be any hope of attaining a rational explanation. This doctrine agrees substantially with that of some logicians; but it is radically at variance with a common theory and with a common practice. This prescribes that the reasoner should be guided by balancing probabilities, according to the doctrine of inverse PROBABILITY (q. v.). This depends upon knowing antecedent probabilities. If these antecedent probabilities were solid statistical facts, like those upon which the insurance business rests, the ordinary precepts and practice would be sound. But they are not and cannot, in the nature of things, be statistical facts. What is the antecedent probability that matter should be composed of atoms? Can we take statistics of a multitude of different universes? An objective probability is the ratio of frequency of a specific to a generic event *in the ordinary course of experience*. Of a fact *per se* it is absurd to speak of objective probability. All that is attainable are subjective probabilities, or likelihoods, which express nothing but the conformity of a new suggestion to our prepossessions; and these are the source of most of the errors into which man falls, and of all the worst of them. An instance of what the method of balancing likelihoods leads to is the 'higher criticism' of ancient history, upon which the archaeologist's spade has inflicted so many wounds. Cf. PRESUMPTIVE INFERENCE.

RECALL — RECAPITULATION

The third elementary way of reasoning is *deduction*, of which the warrant is that the facts presented in the premises could not under any imaginable circumstances be true without involving the truth of the conclusion, which is therefore accepted with necessary modality. But though it be necessary in its modality, it does not by any means follow that the conclusion is certainly true. When we are reasoning about purely hypothetical states of things, as in mathematics, and can make it one of our hypotheses that what is true shall depend only on a certain kind of condition—so that, for example, what is true of equations written in black ink would certainly be equally true if they were written in red—we can be certain of our conclusions, *provided no blunders have been committed*. This is ‘demonstrative reasoning.’ Fallacies in pure mathematics have gone undetected for many centuries. It is to ideal states of things alone—or to real states of things as ideally conceived, always more or less departing from the reality—that deduction applies. The process is as follows, at least in many cases:

We form in the imagination some sort of diagrammatic, that is, iconic, representation of the facts, as skeletonized as possible. The impression of the present writer is that with ordinary persons this is always a visual image, or mixed visual and muscular; but this is an opinion not founded on any systematic examination. If visual, it will either be geometrical, that is, such that familiar spatial relations stand for the relations asserted in the premises, or it will be algebraical, where the relations are expressed by objects which are imagined to be subject to certain rules, whether conventional or experiential. This diagram, which has been constructed to represent intuitively or semi-intuitively the same relations which are abstractly expressed in the premises, is then observed, and a hypothesis suggests itself that there is a certain relation between some of its parts—or perhaps this hypothesis had already been suggested. In order to test this, various experiments are made upon the diagram, which is changed in various ways. This is a proceeding extremely similar to induction, from which, however, it differs widely, in that it does not deal with a course of experience, but with whether or not a certain state of things can be imagined. Now, since it is part of the hypothesis that only a very limited kind of condition can affect the result, the necessary experimentation can be very quickly completed; and it

is seen that the conclusion is compelled to be true by the conditions of the construction of the diagram. This is called ‘diagrammatic or schematic reasoning.’

Recall: see REVIVAL.

Recapitulation (law of) [Lat. *re + caput*, head, through Fr.]: Ger. *Wiederholungsgesetz*; Fr. *loi de récapitulation*; Ital. *legge di ricapitolazione*. The theory according to which the individual in his ontogenic development passes through a series of stages which represent successive forms in the descent of the species (phylum) to which he belongs; the theory that ontogenesis recapitulates phylogenesis. Cope suggested the term ‘Bioblastology’ for the science of the relation of the two genetic series of forms. Cf. ONTOGENY.

The facts were recognized—so far as the parallelism is concerned—by Agassiz, and formulated, for the development of the embryo, by v. Baer (see v. BAER’S LAW). Haeckel interpreted the principle as a law of evolution. It is now very generally recognized as, in principle, true, although liable to much variation due to other forces and conditions. Modifications of it have been formulated in the ‘law of ACCELERATION’ (q.v.), and the theory of abbreviation, with that of SHORT CUTS (q.v.). Eimer (*Organic Evolution*, Eng. trans., 30) makes the following general statement regarding abbreviation: ‘Every lower stage of the phyletic growth is abbreviated [in ontogeny] for the benefit of the newer [higher].’ Variations in the series have been recognized as arising from the necessary accommodation of the organism to changed environment, and the effects of mechanical forces, of unlike and unequal food-supply, &c. (Sedgwick). Moreover, it has been pointed out, by the present writer, that the rigid working of recapitulation must have been subordinated to the requirements of the creature’s own survival—variations in recapitulation coming under the action of natural selection. Thus the rise of an infancy period is necessitated by the demands of later life in creatures in which plasticity and intelligence take the place of fixity and instinct. Such creatures are born helpless, and depend upon parental care, thus failing to pass through the stage of rich instinctive endowment which would correspond to that of their ancestors. So

in the child we find few perfect instincts, and only those—such as sucking, walking reflex, &c.—which are of continued utility, or at least not of actual inutility, in the development of the future mature being whose life is mainly one of intelligent learning. Yet there are, it would seem, even in such cases, sufficient indications of the general operation of recapitulation.

The facts upon which this law is based afford one of the strongest arguments for the theory of organic evolution. How, it may be asked, could the individual's hereditary impulse have come to take this course through a series of forms arranged in order, analogous to a series of adult forms, except by being in the actual line of descent from those forms, which have thus handed down these rudimentary or vestigial (see VESTIGE) indications? And further: how could the line of progress in the individual's development take place, except by actual continuity of material and of vital change from one of these stages to another? So the production of the original series of animal forms, which this recapitulates, must have involved continuity of substance and actual descent by heredity. If these two points be put together—a creature (1) itself showing the actual production of these forms one from another, and (2) itself in the series by hereditary descent—the presumption of evolution is overwhelming.

The term 'parallelism' has been used for the fact of recapitulation especially by Hyatt and Cope (*Prim. Factors of Org. Evolution*, 175 ff.); it is better, however, to restrict that term to psychophysical PARALLELISM (q. v.). The two last-named writers hold, on the basis of discoveries by Hyatt, to a further 'parallelism' between old-age degeneration and racial degeneration (see Cope, as cited above, and cf. ONTOGENY).

Literature: see under v. BAER'S LAW, EVOLUTION, EVOLUTION (mental), and ONTOGENY; MILNES MARSHALL, Lectures and Addresses (being Pres. Address. Brit. Assoc. 1890); also citations in DELAGE, Structure du Protoplasma, and successive issues of the *Année Biol.* (J.M.B., C.L.L.M., E.B.P.)

Recept [Lat. *recipere*, to take back]: not in use in the other languages. A word used by Romanes for the mental images supposed to be formed merely by the repetition of percepts leading to reinforcement of the characters in which the percepts agree, and obscuration of the characters in which they differ. The ordinary psychological term

applied in this connection is **GENERIC IMAGE** (q. v.). (G.F.S.)

Receptivity [Lat. *recipere*, to take back]: Ger. *Receptivität* (Kant), *Empfänglichkeit*; Fr. *réceptivité*; Ital. *recettibilità*. (1) The receptive—i. e. sensory, cognitive, and suggestive—functions as set over against the motor, expressive, and active.

(2) Sensitiveness or responsiveness to stimulation of the receptive functions.

A person is said to be by nature receptive to 'suggestion,' to instruction, &c., or to have great receptivity. Receptibility (with receptive) is also used in this sense.

(3) With Kant, *Receptivität* is the faculty of presentation (*Vorstellen*) when stimulated by objects, as over against *Spontaneität*, in which presentations are brought up by the mind itself ('das Vermögen, Vorstellungen selbst hervorzubringen'; *Krit. d. reinen Vernunft*, 76; quoted by Eisler). (J.M.B., G.F.S.)

Reciprocal Demand: Ger. *gegenseitige Nachfrage* (little used); Fr. *demande réciproque*; Ital. *domanda reciproca*. The relation between two kinds of goods in the same market, wherein either may be regarded as a cause of demand for the other.

If we regard demand not in the sense of quantity demanded, but of purchasing power offered, the source of the demand for one commodity is the supply of others; and each commodity brought to market appears in the double aspect of supply and (source or measure of) demand. The logical consequences arising from this view of the matter were well developed by Cairnes, and still better by Walras, who has made them the subject of acute mathematical analysis. But the superior convenience of the other definition of demand as quantity demanded has prevented most economists from adopting this method of treatment. (A.T.H.)

Reciprocity [Lat. *reciprocatus*, from *recipere*, to receive]: Ger. (1) *Wechselwirkung*, (2) *Widerspiel*; Fr. (1) *échange mutuel*, (2) *réciprocité*; Ital. (1) *scambio mutuo*, (2) *reciprocità*. (1) Relation of **MUTUALITY** (q. v.); mainly used (a) for the action and reaction of all bodies upon one another: Kant's **CATEGORY** (q. v.) of reciprocity; and (b) for the supposed relation of mutual cause and effect between mind and body.

(2) Interaction; double relation of give and take, whether the two relations between giver and taker be the same or not; that is, whether mutuality be present or not.

'Interdependence' is often used to cover

RECOGNITION

both meanings given, and also INTERACTION (q.v.).

Literature: see CATEGORY, and INTERACTION. (J.M.B.)

Recognition [Lat. *re* + *cognitio*, knowledge]: Ger. *Wiedererkennen* (-nung); Fr. *reconnaissance*, *récognition* (sometimes used—L.M.); Ital. *riconoscimento*, *ricognizione*. The consciousness accompanying any mental object when it is apprehended as having been apprehended before.

The principal facts to be covered fall under certain headings: (1) The ordinary recognition of an object as having been apprehended before—as having ‘individual identity.’ (2) The recognition of an image as a memory of an object before experienced. (3) The recognition of an object as being the same, although not having the marks of individual identity—as having ‘material identity,’ i.e. a chair, every part of which has been at some time replaced. (4) The recognition of an object as belonging to a familiar class, although itself as an individual not familiar: ‘class recognition.’ (5) Recognition as attaching to the categories, schemes, or forms of mental process; as to a familiar train of thought, a mathematical demonstration, &c., in which the matter may not be the same: what may be called ‘formal’ or ‘logical’ recognition. (6) The element of self-recognition, which seems to be present in many cases of the recognition of an object. (7) The distinction between (a) relative recognition, in which certain relationships of part to part and part to whole are involved, and (b), in which an absolutely simple quality (e.g. a musical tone; see TONE RECOGNITION) is recognized with no aid from its relationships within or without itself. (8) Illusions of recognition, in which the objects of recognition belonging to the several classes above are falsely held to be familiar.

Theories turn mainly upon the first of these sorts of recognition; but the demand may fairly be made that the final theory explain them all. The principal current views are as follows:

I. Representation theories, which hold that a certain duality as between the former and the latter appearance of the object must enter into recognition: there is a representative or ideal ingredient which gives to the new cognition its value of familiarity. Of these theories we have the following:

(a) The Image theories. According to this view we recognize an object by means of

a memory image of the same object as earlier experienced. The memory image is recalled, and it is found to be the same with the new presentation, hence the latter has its identification. This theory is now generally abandoned in view of the evidence that in many cases of recognition there is no such revived image.

(b) The Assimilation theory. According to this point of view, while there may not be a distinct memory image of the object felt to be familiar, yet there are, in the construction of the object the second time, elements of revived content. These, together with memory elements having more or less conscious value, which do not thus enter into the construction, give the quality of familiarity. The new object is said to be assimilated to the old, so that there is only one mental construction—not an image plus a percept. This is part of the broader theory of ASSIMILATION (q.v.), by which association of ideas is also explained, recognition involving association of a certain sort.

II. The Presentation theories. These take as point of departure, as opposed to the representation view, some mark, quality, or ‘coefficient’ in the thing recognized, whereby it is apprehended as familiar. What is this quality?—that question gives rise to various more specific views.

(a) Physical theories. The recognition coefficient is said to be physical; a certain result left in the brain paths or centres whereby, on the recurrence of the same sort of stimulation or function, a peculiar quale is imparted to the conscious state; this is the feeling of familiarity.

This may be a true statement so far as the fact of nervous HABITUATION (q.v.) is concerned; but it is not a psychological explanation, and so can never be confirmed. If this be all, then the mental coefficient is an ultimate psychic fact or quale, and analysis can go no further.

(b) Objective theories. By these the coefficient is said to be something in the presentation; some character whereby it is different from the original object, but just by this difference is identified objectively with it. This theory finds the element of sameness in the relative complexity of the two presentations alike, and makes the recognition dependent upon the reinstatement of the internal relationships of the content recognized as a whole.

There is much evidence in support of this

view. Complex presentations—as a human face—are recognized with relative certainty and ease; simple ones—a musical tone—with difficulty or not at all. Experiments have indeed made it fairly certain that for the ordinary cases of individual recognition, relative complexity of content enhances recognition. It is evident, however, apart from cases of recognition in which this complexity is not present, that this may be only a means or stimulus to the real recognition process, i. e. that the coefficient may be something yet more recondite to which this objective complexity contributes, but to which it is not essential.

III. Subjective or Functional views. These look upon the mechanism of the mental process, rather than the character of the object, as the locus of recognition.

(a) The Psychophysical Functional view: which makes the principle of habituation apply to the whole function rather than to the physical merely (II, a, above). This, however, in itself is open to many interpretations, according as this or that aspect of the entire act of representation is taken into account. This view therefore tends to pass over into either a purely physical theory or into some view which arises by analysing the mental process to locate the actual coefficient. This view as a whole is then distinguished as—

(b) The Psychical Function view. It takes on several forms, each in turn reaching a more restricted field of mental data and attempting a broader outlook upon the facts.

(i) The Mental Habit view: which simply asserts that the mental life is dominated by a law of habit; and this habit, which depends upon repetition or reinstatement of function, is reflected in consciousness as feeling of familiarity, when the objective repetition stimulates it. If this theory is more than a mystic analogy from physical habituation, it reduces to the latter; if made more precise, it takes on one of the following forms:

(ii) The Mental Disposition theory. This finds that all mental function in some way sets a tendency to the performance of the same or of analogous functions. It makes use of the facts upon which the law of RELATIVITY (q. v.) of sense qualities is based, and which show that the mental life is continuous, and that all process is a resultant of two factors—first, the direct present stimulation, and second, the foregoing mental process. The latter factor is the mental disposition; consciousness is disposed or predisposed to certain

functions. This colours the results of new process, and this colouring in the case of repeated experience is the consciousness of familiarity. This view, in so far, gathers up the facts better than any other. It accounts for the ease of objective recognition, since greater complexity and definition are then imparted to the dispositions involved. It accounts for ‘absolute’ recognition, since it is not dependent upon objective complexity of stimulation. It accounts for illusions of recognition, since the dispositions may become predominant and so give a false colouring to an object of presentation. Its defect is its generality and lack of determination of the actual basis of what is called the disposition involved.

(iii) Motor and Emotion theories.

(a) General theories: which accept the disposition view, but restrict the dispositions involved in recognition to those of conative or affective character. Of these, the recent theory of ‘affective memory,’ which involves direct recognition of affective states as such, is possibly of some importance. The ‘synergy’ theory holds to the flowing together of old and new motor processes in the act of recognition analogous to—or to account for—the ‘assimilation’ presupposed by the theory of that name above (I, b).

(b) Attention theories. These accept the theory of psychic disposition, but narrow down the application in this case to the dispositions of the attention. Attention, it is held, is rendered easier by repetition. This sense of facilitated attention is the subjective side of recognition, and constitutes the coefficient.

This theory, it is held by its advocates, has all the advantages of the functional theory in general, and gains besides from its definiteness. The attention is the vehicle of all cognition or cognitive synthesis; hence variations of the psychophysical process of attention arise from all degrees and forms of relative simplicity or complexity, as well as from different qualities and intensities, of presented contents. Attention furthermore attends all the higher operations of mind. The reinstatement of a mental object, of any character, will be attended by relative dispositional facility, not of attention in general, but of the peculiar attention—visual, auditory, affective, conative, logical, &c.—which is a reflex of the content in question. This relative disposition of attention is the coefficient of the object apprehended as familiar.

If we employ the formula for the analysis

of the ATTENTION (q. v.) given under that topic—*Att.* (attention) = $A + a + a$, we have three categories of attentive recognition of mental objects: first, variations in a —the elements of attention to particular objects, such as sensations of visual accommodation, &c.—give recognition of individual objects (e.g. my pen, recognized visually, is the same I wrote with yesterday). Second, variations in a —the elements common to objects of the same class, but varying for different classes, as cognized by visual, auditory, or other attention—give recognition of objects as not individually familiar but as belonging to a familiar class; such as the recognition of the pen as a pen, not a pencil or a penknife. Thus this theory accounts for a class-recognition. Third, the variations in A —the fundamental groundwork of sensations, &c., common to all acts of attention—give recognition to the great categories, definitions, or modes of experience and thought within which classes of objects are subsumed and treated (e.g. the material IDENTITY, q. v., of objects as spoken of above.)

This last form of recognition has never had statement as a problem of recognition co-ordinate with the others, and there are no theories save this to account for it. It amounts to a genetic theory of the origin of the mental categories considered as modes of classifying and treating experiences. The problem of class recognition also gets its best solution on this theory.

(γ) The Self-recognition theory: the view that the recognition of an object always involves a certain emphasis or assertion of self as being present and also as being the same at both occurrences of the object. This theory, however, requires an analysis of the self thus recognized, and a theory of the act of recognition of this self. It seems to have justice done it in the subjective or functional theories, especially by the 'attention' theory; for it is rather the general or formal presence of the self that accompanies the recognition of the object, than a distinct act of apprehension of the self as such. This formal self is implicit in the function by which the act of recognition of the object is accomplished.

It should be borne in mind that the theories now mentioned are not by any means in all cases mutually exclusive. Many avail themselves of two or more of the explanations offered, or hold, besides the main explanation, various subsidiary hypotheses. For example, the 'attention' theory is also a 'synergy'

theory with respect to the way the dispositions fuse with the newly stimulated attention processes, an 'assimilation' theory with respect to the actual relation of the new objective content to old memory images and sensational revived contents, and a 'subjective' theory with respect to the question as to whether the essential coefficient of recognition attaches to the object recognized or resides in the mental function of apprehension.

Literature (after certain of the authors' names a catchword is given to indicate the class of views which they respectively hold): the topic 'Recognition' in the psychologies of JAMES (physical), HÖFFDING (psychophysical, functional), STOUT (disposition), WUNDT (habit, assimilation), LIPPS (subconscious image), LADD (ultimate datum: 'recognitive memory'), McCOSH (self), BALDWIN, MENT. Devel. (attention). The older works, such as HAMILTON, Lects. on Met., and BROWN, Inq. into the Phenom. of the Human Mind, hold the 'Image' view. See the literature of MEMORY. On the recognition of affective states see HORWICZ, Psychol. Analysen; RIBOT, Imagination créatrice; URBAN, Psychol. Rev., July, 1901 (with literary citations). On 'absolute' (and 'relative') recognition see under TONE RECOGNITION. For experimental researches, see MEMORY (experiments on). (J.M.B., G.F.S.)

Recognition (absolute and relative): see RECOGNITION, *passim*, and TONE RECOGNITION.

Recognition (experiments on, and method of): see MEMORY (experiments on).

Recognition (Hegel's *Anerkennung*): see ACCEPTANCE.

Recognition Marks (or **Markings**): Ger. *Erkennungszeichen*; Fr. *signes récongnitifs*; Ital. *segnî di riconoscimento*. Those characters by which animals, especially those of the same species, recognize one another.

The view that the utility of various markings—colour, &c.—is that of aiding recognition for mating and other purposes has been developed by Wallace (*Darwinism*, 1891, 217 ff.; see also Poulton, *Colours of Animals*, 210 ff. and Index; and Gulick, *Nature*, Apr. 1, 1897). (J.M.B., E.B.P.)

Recollection [Lat. *re + colligere*, to collect]: Ger. *willkürliche Reproduktion*; Fr. *reproduction volontaire*; Ital. *ricordanza*. Volitional REPRODUCTION (q. v.); reproduction following and controlled by the volition to reproduce. (G.F.S.—J.M.B.)

Recovery [Lat. *recuperare*, through Fr. *recouvrer*, to regain that which was lost]: Ger.

(*Wieder-*) *Genesung* (of health), *Erholung*; Fr. *convalescence* (of health), *recouvrement*; Ital. *ricupero*. The process of regaining normal condition after fatigue, disease, or injury. If not complete it is termed 'partial recovery.'

(C.F.H.)

Rectitude [Lat. *rectitudo*, from *rectus*, right]: Ger. *Rechtlichkeit*; Fr. *rectitude*; Ital. *rettitudine*. (1) FORMAL RIGHTNESS (q. v.); cf. also EQUIVOCATION.

(2) Correct moral habit and disposition.

This usage is essentially based on meaning (1), since it takes account primarily of the will to do right rather than its accomplishment. In rectitude, in both senses, stress is laid on the more precise—and sometimes austere—recognition of the claims of justice, self-denial, and those virtues generally which fulfil the letter of obligation.

(J.M.B.)

Recurrent [Lat. *recurrere*, to run back]: Ger. *recidivierend*; Fr. *récurrent*; Ital. *ricorrente*. Reappearing after intervals. Recurrent insanity is a well-known type, particularly in mania. Cf. PERIODICITY.

(J.J.)

Recurrent Resemblance: see RESEMBLANCE (table, II).

Recurrent Vision: Ger. the Eng. term, also *Purkinje-Nachbild*, *Nachbild nach kurz-dauerndem Reize*; Fr. *vision périodique*, *image récurrente positive*; Ital. *visione ricorrente*. After brief excitation, the positive AFTER-IMAGE (q. v.) has been found to consist of several successive or 'recurring' stages, interrupted by negative phases.

C. A. Young: 'When, in a darkened room, the eye is screened from the direct light of the [intense Leyden jar] spark, the illumination produced is sufficient to render everything in the apartment perfectly visible; and what is remarkable, every conspicuous object is seen twice at least, with an interval of a trifle less than one-quarter of a second—the first time vividly, the second time faintly; often it is seen a third, and sometimes, but only with great difficulty, even a fourth time. The appearance is precisely as if the object had been suddenly illuminated by a light at first bright, but rapidly fading to extinction, and as if, while the illumination lasted, the observer were winking as fast as possible. . . I have ventured to call the phenomenon recurrent vision' (*Amer. J. of Sci. and Art*, iii, Mar. 1872; cf. *London, &c., Philos. Mag.*, May, 1872). In Germany the phenomenon is associated with the name of Purkinje (as cited below).

Analogous phenomena have been de-

scribed by others. C. A. Davis (art. 'Recurrent Vision,' *London, &c., Philos. Mag.*, xlv, 1872, Suppl., 526) gives the following: 'If the end of a piece of charcoal be made red-hot in a flame, and then moved about in the dark so as to describe an ellipse or circle a few inches in diameter, a blue image of the burning end is seen following the charcoal at a short distance behind it. The space between the charcoal and the blue image is as dark as the surrounding space.'

The following experiment described by Charpentier was made by him the basis of a hypothesis of retinal oscillation, which has now been used by him to explain colour vision. Rotate slowly a black disk that has a white sector of 90°; fixate the centre; the retreating black edge is followed by a narrow shadowy sector in the white. (E.B.T.—J.M.B.)

Bosscha (who has since been confirmed by others) speaks of the secondary, the tertiary, and the quaternary stage; the last being the regular negative after-image. Counting the dark intervening phases, there would be seven stages in all. This alternation of images was disquieting to those who believed the phenomenon to be retinal, and induced some to refer the whole process of the after-image, and consequently the extinguishing of complementary colors also, to the cortex. But the subject has been very much cleared up by Munk (*Zeitsch. f. Psychol.*, xxiii, 1900). He finds that the real course of the phenomenon is that the gradually falling away original excitation undergoes a sudden, delayed shock of contrast from the surrounding dark field; this constitutes the secondary image (which is of complementary colour with the first); after this is over, the regularly diminishing original excitation is again perceived. The proof is that the whole phenomenon is lacking, including the change of colour, if there is no dark contrasting background. The fact that the phenomenon is found (at least, by some observers) not to occur when the fovea only is stimulated (v. Kries, Hamaker) points to the achromatic apparatus (the rods) as the source of the sudden (secondary) accession of brightness. That in colour the after-image changes from positive to negative when white light is thrown upon it is the common rule. In view of this result, the best name for the positive AFTER-IMAGE (q. v.) is *persistent retinal image* (Parinaud), as affording an indication of its character.

The phenomena are markedly different (Hamaker), according as the method of looking

for a short time at a resting light (method of Brücke, 1851), or that of fixating a point while a light moves through the field of view (method of Purkinje), is employed. (C.L.F.)

(C.L.F.—E.B.T.—J.M.B.)

Redeemer [Lat. *redimere*, to redeem]: Ger. *Erlöser*; Fr. *Rédempteur*; Ital. *Redentore*. The term applied to Jesus Christ as the rescuer and saviour of men from sin and its effects. Applied in a secondary sense to religious prophets in general. (A.T.O.)

Redemption [Lat. *redemptio*, from *redimere*, to redeem]: Ger. *Erlösung*; Fr. *réemption*; Ital. *redenzione*. In Christian theology, salvation from sin and its effects through the atoning work of Jesus Christ.

Redemption is a name for the scheme of Christian salvation as a whole.

Literature: see ATONEMENT, and CONVERSION. (A.T.O.)

Redintegration [Lat. *re + integratio*, from *integer*, whole]: not in use in Ger. and Fr.; Ital. *reintegrazione*. The reinstatement of a total presentation by a partial constituent of it.

Hamilton first introduced this term. He recognizes two fundamental laws of reproduction. The first is that of 'repetition,' which he states as follows: 'Thoughts coincidental in modification but differing in time tend to suggest each other.' The second is that of redintegration: 'Thoughts once coincidental in time are, however different as mental modes, again suggestive of each other, and that in the mutual order which they originally held.' He adds by way of explanation that unity of time involves a totality of thought, 'and that the partial thoughts included in the totality tend immediately to suggest each other as co-constituents of this former whole, and mediate that whole itself.'

When Hamilton says that the whole is only immediately reproduced because the parts are immediately reproduced, he seems to deprive the term redintegration of all distinctive meaning. It is not clear from this point of view that there is any advantage in substituting it for the more familiar 'association by contiguity.' On the other hand, there is a clear gain if the term be taken to denote the tendency of the part to reproduce the whole *as such*, including not merely the other partial constituents, but also their special mode of combination with itself and with each other.

The term redintegration is used by Shadworth Hodgson for associative reproduction in general. He does not, like Hamilton, recognize a distinct law of repetition.

Literature: HAMILTON, Ed. of Reid, ii. Notes D**, D***; S. HODGSON, Met. of Exper. (Index, sub verbo). (G.F.S.)

Reductio ad absurdum [Lat. trans. of Aristotle's ἀπαγωγή εἰς τὸ ἀδύνατον]. The disproof of a proposition by showing that among its consequences there is one which is impossible or simply false.

This mode of proof is generally considered to be unsatisfactory, as not showing on what general principle the proposition disproved is false. But it is very easy to convert any such proof into a direct proof. Take, for example, the seventh proposition of the first book of Euclid, that on the same side of the base AB two triangles ABC and ABD cannot exist having $AC = AD$ and $BC = BD$. Euclid proves this by showing that if there were two such triangles it would follow that the angles BDC and BCD were equal and also that they were unequal. But precisely the same steps of reasoning show that if there are two triangles ABC and ABD on the same side of AB , and if $AC = AD$, then BC is unequal to BD , which shows that there are not two triangles having $AC = AD$ and $BC = BD$, since things unequal are not equal. (C.S.P.)

Reduction [Lat. *re + ducere*, to lead]: Ger. *Zurückführung*; Fr. *réduction*; Ital. *riduzione*. (1) The process of bringing an object from its given form into some standard form or state, for purposes of clearness, certainty, or use.

(2) In logic, the process of bringing a syllogism into the standard form of the first figure.

Thus a syllogism of the second figure, such as

No P is M
No S is P,
—————
No S is M

may be reduced to the first figure by simply converting the first premise.

In dealing with the syllogism (*Anal. Prior.*, Bk. I), Aristotle regards the first figure as the complete or 'perfect' type of syllogism. The two other figures of syllogism recognized by Aristotle require, in order to make perfectly clear their actual force, the addition of immediate inferences from the premises, or other alteration of their structure, whereby they come to be stated in the first figure. These additions Aristotle states at some length. The devices for the reduction of the incomplete syllogisms, or of those of other figures, to the form of the first figure, were later developed in the textbooks of logic into a series of rules, kept in mind through mnemonic devices. Recent psychology has very generally tended to vivify these formal rules for reduction by efforts at new statements of the fundamental nature and of the true form of the syllogism. (J.R.)

Reduction has been recognized as necessary by Aristotle and almost all logicians; and before Kant it was generally recognized as proving that indirect syllogisms involved two or more steps of inference. But Kant from the same premises inferred that reasoning in the first figure is the only reasoning; and this extraordinary conclusion is reached by simply not calling immediate inferences reasoning, because they have not two premises. On that ground, nothing ought to be called reasoning except uniting two propositions into one copulative proposition. Cf. SYLLOGISM.

Reduction is either *ostensive* or *apagogical* (*per impossibile*). Ostensive reduction proceeds directly from the premises of the syllogism to be reduced to its conclusion, by means of conversions and a direct syllogism. Apagogical reduction proceeds indirectly by showing by direct syllogism that from the denial of the conclusion of the syllogism to be reduced and one of the premises the denial of the other premise would follow. Any syllogism of the second figure and any of the third except Darapti and Felapton (which are not valid if the universal be taken in the Philonian sense) can be apagogically reduced.

Ostensive reduction is either short or long. Short reduction involves the conversion of one proposition only; long reduction the conversion of two propositions, and, except in the fourth figure, the transposition of the premises.

In order to ascertain that which reduction is intended to ascertain, the nature of the different moods of syllogism, the first requisite

is to recognize that we do not seek to trace out the process of reasoning; but what we seek to do is to analyse the precise logical conditions which render each mood valid. When this is recognized, it becomes easy to see and to generalize the relations expressed by the premises and note just at what point they cease to be cogent. For this purpose, appeal must be made to the logic of RELATIVES (q. v.). De Morgan has worked out the moods (*Cambr. Philos. Trans.*, x. 350). (C.S.P.)

Reduction-division: Ger. *Reduktions-theilung*; Fr. *division réductionnelle*; Ital. *divisione riduttiva*. The special form of CELL DIVISION (q. v.) which results in the formation of gonads (male or female elements).

As gonads have half the number of chromosomes found in the somatic cells of a given species, whenever gonads arise from cells there must be effected a reduction of the number of chromosomes. This reduction is completed during the final division of the cells, hence the term reduction-division. When the male or female nuclei fuse in the process of fertilization, the chromosomes are again brought up to their usual number. See SEX, CHROMOSOME, and FERTILIZATION.

Literature: HENNEGUY, *La Cellule*; E. B. WILSON, *The Cell in Devel. and Inheritance*; HERTWIG, *Die Zelle*. (C.S.M.)

Reduplication: see Recurrent Resemblance under RESEMBLANCE.

Reduplication (in biology): see SEGMENTATION.

Reflection [Lat. *reflectio*, from *re* + *flectere*, to bend]: Ger. *Reflexion*; Fr. *réflexion*; Ital. *riflessione*. (1) In popular language, any train of thought following a first impulse to believe or act, and reversing, modifying, or confirming it.

(2) Its technical meaning in psychology may be stated in the words of Locke: 'That notice which the mind takes of its own operations and the manner of them' (*Essay*, i. 78, § 4).

Reflection, in its psychological use, has a narrower application than 'self-consciousness,' and a wider than 'introspection.' All awareness of the self with its states comes under SELF-CONSCIOUSNESS (q. v.). But such awareness is not reflection unless interest and attention is predominantly directed to the self and its state. When I fail to hit a mark with a missile I become aware of myself as disappointed, and to that extent I am self-conscious. But I may not stay to think about my subjective state. On the contrary,

REFLECTION — REFLEX ACTION

the main current of interest may still be directed to the mark and the means of hitting. I may at once pick up another stone and take aim again. In this case I do not reflect on my disappointment. I am merely aware of myself in an incidental way.

INTROSPECTION (q. v.), on the other hand, marks a more sustained interest in the self and its processes than reflection. It is reflection exercised with the view of obtaining accurate and systematic knowledge of mental operations.

The metaphor implied in the term reflection is that of 'turning back' upon something. It seems to indicate the indirect nature of the cognition of the self. In order to know ourselves we must first know something else. In order to have cognizance of the process of attending we must first attend, and this primary subjective process must have an object distinct from itself. Cf. **REFLECTIVE**.

Literature: see under **SELF-CONSCIOUSNESS**, and **BIBLOG. G**, 2, t; also much of the literature of **EPISTEMOLOGY**. (G.F.S.—J.M.B.)

Reflection (in method): Ger. *Besinnung*; Fr. *réflexion*; Ital. *riflessione*. The conscious assimilation of knowledge; the counterpart of **ABSORPTION** or **SELF-ESTRANGEMENT** (q. v.), wherein the mind is absorbed in the novel, the strange, the wonderful. (C. De G.)

Reflection (in physics). The change of direction which a ray of light, sound-wave, &c., undergoes when it strikes upon a surface and is thrown back into the same medium through which it approached the surface.

The fact of reflection is pressed into psychological service in optics, e.g. in Lambert's colour-mixer. See **COLOUR MIXTURE**. (E.B.T.)

Reflective (and **Unreflective**): Ger. *reflexiv*; Fr. *réflectif*, *réfléchi*; Ital. *riflessivo*.

(1) Characterizing **REFLECTION** (q. v.); belonging to mental process or content which involves reflection, e.g. reflective consciousness, states, &c.

(2) Contrasted with 'unreflective,' 'spontaneous,' **ORGANIC** (q. v., in psychology), as indicated under the last-mentioned term, e.g. 'reflective' emotion. See **MODESTY**, **SHYNESS**, and **SYMPATHY**.

(3) Deliberate or thoughtful, as applied to an individual.

Unreflective is applied either to what is not reflective, in either of senses (1) and (2), or to what is undeliberate or ill considered.

Literature: see **REFLECTION**, and **ORGANIC** (in psychology). (J.M.B., G.F.S.)

Reflex (conscious): Ger. *bewusster Reflex*; Fr. *réflexe conscient*; Ital. *reflesso cosciente*.

Action following regularly on the mere existence of the same conscious state. Cf. **AFFECT**.

Such action has the fixity and uniformity, and the immediate dependence on the present operation of a stimulus, which characterize the physiological reflex. See **REFLEX ACTION**, **INSTINCT**, and **AUTOMATISM**. (G.F.S.—J.M.B.)

Reflex Action: Ger. *Reflexbewegung*; Fr. *action réflexe*; Ital. (*atto*) *reflesso*. Kinesodic response to aesthesodic stimuli (cf. **AESTHESODIC**) of a regular kind without the intervention of volition or necessary participation of consciousness; or, more popularly, a non-voluntary reaction taking place in the body from stimulation to the brain or other nervous centre. (H.H.—J.M.B.)

A muscular contraction following directly upon an irritation of the skin affords a simple illustration, and the anatomical mechanism for such direct reflexes is illustrated in Figs. 1 and 2, **SPINAL CORD**. The response to the stimulus may be a muscular contraction, a secretion in a gland, a vascular change, or even a trophic or metabolic influence; but it must in each case be regarded as kinesodic or pertaining to the centrifugal system. The stimulus may be of a sort which, under other circumstances, would be appropriate to produce a sensation, or it may be of a character incompetent to appear in consciousness. It must be observed that while reflex action is not conscious action, one may be conscious of the act, and in many cases conscious changes precede, accompany, or occasion the reflex. The table given below sufficiently illustrates the diversity in nature and occasion.

Classification of reflexes (after Harris):

- | | |
|---------------------|--|
| I. Periphero-motor. | |
| 1. Excito-motor. | a. excito-muscular.
b. excito-glandular.
c. excito-vascular.
d. excito-metabolic. |
| 2. Algio-motor. | a. algio-muscular.
b. algio-glandular.
c. algio-vascular.
d. algio-metabolic. |
| 3. Sensori-motor. | a. sensori-muscular.
b. sensori-glandular.
c. sensori-vascular.
d. sensori-metabolic. |
| II. Centro-motor. | |
| 4. Emotio-motor. | a. emotio-muscular.
b. emotio-glandular.
c. emotio-vascular.
d. emotio-metabolic. |
| 5. Ideo-motor. | a. ideio-muscular.
b. ideio-glandular.
c. ideio-vascular.
d. ideio-metabolic. |

Excito-motor reflexes have for their cause some irritant, either mechanical or physiological. Hiccough is excito-muscular in the involuntary system, and the grinding of the teeth in children afflicted with worms in the voluntary system. The secretion of digestive fluids is excito-glandular. Excito-metabolic changes are more rare and less clearly reflex, such as the pigmentation of the skin in disease and pregnancy. Algio-motor or pain reflexes are illustrated by perspiration and lachrymation from pain. Sensori-motor reflexes are seen in the accommodation movements in sensory organs, winking from foreign bodies in the eye, &c., though often the transition to excito-motor is complete. Emotio-motor reflexes are the emotional 'expressions,' such as syncope from fear, sighing, cessation of salivation in fear, lactation from joy, blushing, and even metabolic changes like the whitening of the hair. The reflexes of the ideo-motor group are most difficult to construe, and it is probable that most of the phenomena so classified are really emotio-motor. Ideo-metabolic may be tropho-neuroses or 'stigmata'; but the blushing at a recollection, or salivation at the mental presentation of food, or weeping at an anticipation, differ in no way from the same acts when the occasion is directly presented with the associated emotion.

The most important reflex of all is commonly ignored, viz. that which provides for the constant readjustment of the parts of the system to each other, by virtue of which the entire mechanism is receptive even to minimal stimuli. This may be termed the neuro-equilibrium reflex. The 'tone' of the nervous system is this wonderfully complex adjustment of inhibition and stimulation. Every metabolic process in all the nerve-cells exerts its influence on the entire nervous tone, so that the nervous system is an instrument strung so tensely that its responses to outer irritations are far from being passive outcomes of the impacts.

One of the most remarkable reflex associations is that between vaso-motor alterations and the seat of emotions; though beyond the fact that the viscera and vessels are minutely connected with the sympathetic system, we know almost nothing of the physiological basis for this association. Cf. EMOTION. (H.H.)

Among the most important general questions arising about reflexes are: (a) their mechanism in the centres (ganglia and lower cerebral); (b) their relation to the higher (conscious and voluntary) processes, by which

they are normally inhibited and in a measure regulated; (c) their biological origin. For topics which bear upon these questions see NERVOUS SYSTEM, AUTOMATIC ACTION, SECONDARY AUTOMATIC, CONSCIOUS REFLEX, LIVING MATTER, VOLUNTARY ACTION, and HEREDITY.

Literature: see the textbooks of physiology and physiological psychology. (J.M.B.)

Reformation [Lat. *reformatio*]: Ger. *Reformation*; Fr. *Réformation*; Ital. *Riforma*. The great religious revolution of the 16th century which resulted in the origin and organization of Protestant Christianity.

For the distinctive principles of the Reformation see PROTESTANTISM. Historically, the three great branches of the Reformed Church are the Lutheran, Calvinistic, and Anglican. The disruption caused by the Reformation has given rise to the problem of the reunification of Christendom; the tendencies in that direction have of late been gaining strength.

Literature: see references under PROTESTANTISM; also DÖLLINGER, *Die Reformation*, &c. (1846-8); RANKE, *Deutsche Gesch. im Zeitalter d. Reform.* (1869); D'AUBIGNÉ, *Hist. of the Reformation* (Eng. trans.); BURNET, *Hist. of the Reformation of the Church of England*. (A.T.O.)

Refraction (in physics) [Lat. *refringere*, to break up]: Ger. *Brechung*, *Refraction*; Fr. *réfraction*; Ital. *rifrazione*. The change of direction of rays of light, waves of sound, &c., which are obliquely incident to, and traverse a smooth surface bounding two heterogeneous media, or which traverse a medium of varying density.

The fact of refraction is illustrated, e.g., in the prismatic spectrum, different wave-lengths being differently refracted, and so giving the bands of colour. See ABERRATION (chromatic), and DIACOUSTICS. (E.B.T.)

Refutation [Lat. *refutare*, to repel]: Ger. *Widerlegung*; Fr. *réfutation*; Ital. *confutazione*. Disproof by counter argument. Cf. PROOF, and REASONING. (J.M.B.)

Regeneration [Lat. *regeneratio*]: Ger. *Regeneration*, *Neubildung*; Fr. *régénération*; Ital. *rigenerazione*. (1) In theology: see CONVERSION (in theology).

(2) In biology: the process of new growth by which a lost part is replaced.

All organisms possess the power of regeneration, but it varies, generally speaking, inversely as the specialization or differentiation, being least in the highest animals, greatest in the lower animals and plants; in animals the

regenerative power is also greatest in simple tissues, less in the highly differentiated tissues, and at the minimum in the brain.

Many of the facts of regeneration have long been known, but of late years they have been widely discussed in relation to Weismann's theories. It has generally been regarded as a general and unexplained power of the organism to resume its integrity after the loss of a part. Weismann regards it as a specially developed adaptation to oft-recurring needs under the influence of natural selection. He seeks to prove that it occurs only in those parts of animals which are specially liable to loss; and contends that special germinal rudiments are developed to meet the oft-recurring need. On the other hand, it is held by certain of the experimental morphologists (e.g. Wilson) that cases of regeneration, such as the regeneration of the lens of the eye by injuries which would not happen in actual life, render this explanation inadequate.

Literature (to 2): A. WEISMANN, *The Germ-Plasm* (1892-3); and 'Regeneration' in *Nat. Sci.* (April, 1899; and the literature there referred to); E. B. WILSON, *The Cell in Devel. and Inheritance*; T. H. MORGAN, *Regeneration* (1901). (C.L.L.M.—J.M.B.)

Regress: see PROGRESS.

Regression [Lat. *regressus*, a going backward]: Ger. *Rückkehr*; Fr. *retour au type*; Ital. *regressione*. (1) In biology: the maintenance in a group of animals of a certain type or standard in any given character through the intermingling and levelling effects of heredity, whereby extreme variations are not perpetuated. It should be carefully distinguished from Reversion or ATAVISM (q. v.).

(2) In sociology: sometimes erroneously used for social retrogression and decay. See SOCIAL EVOLUTION.

(1) The principle was first given general formulation by F. Galton. It is important as a conservative factor in evolution, since through it progress, being made by change in the average value of a character, becomes continuous and steady. Sports of all kinds have influence only as single individuals whose characters are balanced by other variations according to the law of distribution about a mean. The influence of a 'sport,' therefore, would be greatest the smaller the group in which he appears. Although operating upon individuals, the net result of natural selection appears in the shifting of the mean value.

The principle was embodied in Galton's

law of the mid-parent (see MID-), and assumes more exact form in the same author's 'law of ancestral inheritance,' known as GALTON'S LAW (q. v.). It has been worked out mathematically on the basis of statistics illustrating Galton's law by K. Pearson, who establishes the relative stability of groups, and introduces a 'coefficient of stability.' Cf. PANMIXIA.

The principle seems, however, to apply mainly in cases of 'blended' inheritance (in which the characters of the two parents blend), and not in cases of 'mutually exclusive' inheritance (cf. Galton, *Nat. Inheritance*, 12, and Ewart, Pres. Address, Sect. Zool., Brit. Assoc., 1901).

(2) The principle has been discussed in connection with social evolution; but it evidently does not apply, since its operation is entirely through physical heredity (the mating of variations of different value). In social life a single individual mind, or a single thought, may dominate and colour all subsequent progress, its propagation being by imitation and tradition. Such propagation is inconsistent with the law of biological regression. If such an analogy held, it would indicate a law of regression (not of retrogression; cf. above, 2) in social evolution.

Literature: GALTON, *Natural Inheritance*; and papers cited under GALTON'S LAW, notably *Proc. Roy. Soc. Lond.*, xi. 401; PEARSON, *ibid.*, meeting of Jan. 27, 1898; *Science*, Mar. 11, 1898, 337 f.; and *Grammar of Science* (2nd ed., 1900); CONN, *Method of Evolution* (1900); HEADLEY, *Problems of Evolution* (1900); other expositions of EVOLUTION (q. v.). On the social application see citations under BIOLOGICAL ANALOGY; also KIDD, *Social Evolution*; LL. MORGAN, *Habit and Instinct*; BALDWIN, *Social and Eth. Interpret.*, sect. 300 ff. (J.M.B., C.L.L.M., E.B.P.)

Regressive (in logic): see PROGRESSIVE (2).

Regret: Ger. *Bedauern*; Fr. *regret*; Ital. *rammarico*. Emotion of sorrow attaching to portions of the past into which one's own voluntary attitudes or acts have entered. Cf. REMORSE, and REPENTANCE.

Regret attaches to things not done, to attitudes of *laissez-faire*, and even of indifference, as well as to positive acts. Some of the keenest regrets attach to opportunities unimproved, to attainments not won. 'Nothing but leaves! The spirit grieves O'er years of wasted life!' (J.M.B.)

Regular [Lat. *regula*, a rule]: Ger. *regel-*

mässig, regulär; Fr. *régulier*; Ital. *regolare*. Conforming to rule.

Regular proof: proof which has the external form considered appropriate to making its cogency clear. The form of a regular demonstration is as follows: first, the proposition to be stated is precisely stated in general terms; second, the construction of a diagram is described conforming to the conditions of the proposition; third, the proposition is restated with reference to the construction; fourth, by means of additions to the diagram, parts of it are brought into comparison; from which it is made evident that the proposition is true of that construction. It is evident that to perfect the proof, it ought then to be shown that what is true of the particular construction will be true in every case.

Regular syllogism: a syllogism which is stated precisely in the standard form, the major premise first, the minor premise next, the conclusion last; and with these propositions in the peculiar language, or symbols, of the system of formal logic used. (C.S.P.)

Regulative: see CONSTITUTION.

Reid, Thomas. (1710-96.) Born at Strachan, Scotland, he was educated at home and at Marischal College, Aberdeen. College librarian and student of mathematics and philosophy, 1726-37, when he became minister at New Machar in Aberdeenshire. Professor of philosophy in King's College, Aberdeen, 1752; of moral philosophy in Glasgow, 1763; resigned 1781, and devoted himself exclusively to philosophy until his death. He was the founder of NATURAL REALISM (q. v.) and its leading figure.

Reify (-fication) [Lat. *res*, thing, + *facere*, to make]: not in use in the other languages. To change a mental attitude or abstraction into a supposed real thing; to attribute objective substantiality to an idea. It is the practical equivalent to hypostatize; see HYPOSTASIS. (J.D.)

Reimarus, Hermann Samuel. (1694-1768.) Born at Hamburg and educated at Jena, he became Privat-docent in philosophy at Wittenberg; travelled in Holland and England; was professor of Hebrew in the Johanneum at Hamburg, 1728. He was one of the figures of the ENLIGHTENMENT (q. v.).

Reinhold, Carl Leonhard. (1758-1823.) Born at Vienna; fled from a Jesuit college, St. Barnabite order, 1783; professor in Jena, 1787-94; successor of Tetens as professor of philosophy in Kiel, 1823, where he died. He

sought for the ultimate principle which would resolve the Kantian dualism of sense and understanding.

Reinhold, Ernst. (1793-1856.) Son of the preceding, he was born and educated in Jena, and became professor of logic, philosophy, and metaphysics in the university there.

Reintegration. Repeated INTEGRATION (q. v.). See also REDINTEGRATION. (J.M.B.)

Rejuvenation [Lat. *reiuvenare*, to make young]: Ger. *Verjüngung*; Fr. *rajeunissement*; Ital. *ringiovanimento*. The production of young tissue or cells of the embryonic type, capable of further growth and differentiation.

Embryonic cells are characterized by the small amount of their protoplasm, and the absence of differentiation in both the protoplasm and the nucleus. In the biological sense old cells are those which are most differentiated, and such old cells are never rendered young; hence rejuvenation in its popular meaning cannot be applied in biology. (C.S.M.)

Literature: MINOT, Senescence and Rejuvenation, J. of Physiol., xii. 97; and Biol. Centralbl., xv. 571; DELAGE, Structure du Protoplasma, and Année Biol. (successive issues); works on biology. (C.S.M.-J.M.B.)

Relation [Lat. *re* + *latus*, p. p. of *ferre*, to bear]: Ger. *Beziehung*, *Verbindung*, *Verknüpfung*, *Verhältniss*; Fr. *relation*, *rapport*; Ital. *relazione*, *rapporto*. See RELATION (consciousness of).

More specifically, (1) Practical. The bearing or influence of one thing upon another—the way one thing 'has to do' with another; for example, the testimony of *A* has relation to the guilt of *B*; the discovery of a new fact has relation to the truth of some theory.

(2) Logical. The mutual dependence of two or more subjects upon a common principle, fact, or truth, of such a kind that any assertion regarding one modifies the meaning of the other. Accordingly the predicate is true or false of one taken not independently or in isolation, but only in reference, regard, or respect to the other.

Examples: the relation of father and son, buyer and seller, of parasite and host. Many qualities may presumably be predicated of *A* which have no bearing upon what is asserted or believed of *B*, but in so far as *A* stands in relation to *B* (as father to son, seller to buyer, &c.), this indifference ceases, giving way to complete (logical) reciprocity. This does not mean that *A* and *B* are the common subjects of the same predicate, or are taken

conjunctively or collectively. On the contrary, they may be affected by quite different, even opposite, predicates; or the predicate of *A* may be clearly asserted, and that of *B* remain quite undetermined. It means only that every assertion regarding *A* carries with it some further assertion regarding *B*; and, conversely, that any assertion regarding *A* is possible only because of some qualification of *B*. Every predicate of either term both depends upon and influences the other. This is possible, however, only if there is some further predicate which is common to both *A* and *B*, and which affords the basis or foundation of the relation in which they further stand to each other—the relationship proper. This relationship is commonly also called the relation; and theories as to its nature bring us to the third type of meaning.

(3) Metaphysical. How can a belief or judgment regarding one fact affect the content of our judgment or belief of another disparate fact? What is the guarantee of the assumption of validity attaching to such a transfer? This is the question of the ontological or real worth of the logical use of the relation. The problem widens its significance tremendously when it is seen that all judgment and inference presuppose just such extension. It is not merely a matter of the possibility of judgment with reference to such obvious correlates as father and son; science rests on the postulate of some sort of relation between any given fact and some other fact—a relation which is the real, even if concealed, foundation of any scientific statement about either one taken separately. Thus the question of the truth conveying power of logical procedure is bound up with the question of the nature of relations. Various types of answer are afforded to the question.

(i) It is asserted that relations have no objective existence or counterpart. Relations are a purely mental product, stating something which emerges when facts having really nothing to do with one another are held before the same mental view, or are compared. This theory is of course the analogue of the older nominalism and conceptualism, the modern relation being the equivalent of the mediaeval universal. A relation is like a rhetorical simile. To compare a star and a tear institutes a relation between them *ad hoc* for the mind that compares; beyond that, nil. The same sort of thing (and no more) is true of a relation of cause and effect. Only sceptical philosophers

have, however, carried the theory to this logical result. Most of the empiricists (who are characterized by their adherence to this view) assume without questioning that they have a right to the relation of resemblance; many fall back upon succession in time and co-existence in space, and (possibly) uniformity in the repetition of these successions and coexistences—an admission which the rationalists have seized upon to the undoing of this subjective notion of relations.

(ii) Another view, the popular survival of the realism of the middle ages, reinforced by pre-evolutionary zoology and botany, is that different things form natural classes, families, or kinds, and that it is in virtue of membership in the same sort or genus that things stand related to one another. The *εἶδος*, the form or species, is thus the ontological counterpart of the logical relation. As long as this view prevailed, the term relation was comparatively little used; universal doing service on the ontological side, and predication on the logical. With the growth of nominalism; with the scientific tendency to replace genera by laws; with the development of the view (3, i), making relations the products not the bases of classification, and classification a subjective instrument, another *fundamentum relationis* had to be found.

We have (iii) the tendency to view relation as equivalent with *law*. This is favoured by the common tendency to confuse law and force; the relation of gravitation, the law of gravitation, the force of gravitation, are to many minds practically synonymous. Or, if the matter be pressed somewhat further, it would probably be admitted that while the relation is a way of viewing things, and hence intellectual only, the related things are somehow 'connected' by a law which gives authority to the relation. It is clear, however, that this is a purely popular solution, evading the issue by circular reasoning.

(iv) Modern idealistic metaphysic has recognized with (3, i) that relations are connected with the process of judgment, but has attempted to invest relations with validity by regarding the world as the content of a single, permanent judgment, and hence made up of a system of relations. To try to follow the course of this argument would almost be to write the history of metaphysical logic since the time of Kant; but the following points may be briefly indicated. The notion

of a hierarchy of forms, genera, species, &c., is wholly given up; it is recognized that the problem is in reality that of the possibility of a valid judgment. All real judgment is synthetic—that is, involves the carrying over of a predicate of one subject to affect the predicate of another subject numerically distinct. Any other form of proposition is tautological, and hence no judgment at all. Judgment as such is therefore bound up essentially, and not merely by occasion, with the question of the reality of relations. This positive conclusion is reinforced by noting that the denial of reality to the relations instituted in judgment leads to complete scepticism, and destroys the whole fabric of science; and by noting that even the more thorough-going empiricists (or non-relationists) are obliged to assume the relation of resemblance or similarity in order to give mental viewing together, or comparison, any basis. Summarizing, we may say that, according to this theory, a relation is a permanent and necessary mode of judgment by which objects, and the world as the object, of knowledge are constituted.

(v) This view has to contend with three inherent difficulties:—

(a) In emphasizing relational knowledge, it appears to make discursive or reflective thought the type of all thought, and to have no place for intuitive consciousness or immediate identification of subject and object.

(b) It emphasizes the intellectualistic view of the universal, reducing feeling and will to forms of cognitive judgment.

(c) It presupposes qualities, or an unrelated manifold of some sort upon which the relating activity is exercised. Hegel accordingly gave relations a central position in the logic of reflective cognition, and consequently in the world of appearance and essence, but regarded this realm as intermediate between a sphere of immediate perceptive recognition and a region of rational intuition apprehending self-related wholes. Of Hegel it must be said that he never made clear just the connection between the self-related whole and the self-contradictory scheme of relations which it includes and supersedes. As Green (*Prolegomena to Ethics*) gives the most consistent modern rendering of Kant, so Bradley, in his *Appearance and Reality*, follows Hegel most successfully in pointing out the phenomenal character of any system of relations, and the necessity of a more immediate and harmonious whole in which relations as such cease.

(vi) There is a growing tendency to recur to the simple, practical statement of relation as the 'having to do' of one thing with another in the way of effecting some result in which one is interested, and to classify and generalize this point of view into a systematic philosophy. See PRAGMATIC. [This is especially due to the recognition of 'forceful' or dynamic, and genetic, relations.—J.M.B.]

According to both (iv) and (v), relations are reducible to the identity-in-difference function of judgment (the disagreement between them being as to the absolute or merely phenomenal significance of judgment), and are the various modes in which this function progressively manifests itself. According to the view now stated, they are reducible to different forms of the means-and-end function—that is, while they develop out of judgment, judgment itself is an attempt to state experience with reference to discovering valuable ends and appropriate means of realizing them. The 'relations' are thus objective definitions of the various influences which things have upon one another *practically*, that is, in the way of helping or hindering the attainment of aims, or in suggesting desirable modifications of these aims. The ultimate worth of this objective or intellectual statement of practical bearings is itself practical—that is, it facilitates the harmony and expansion of experience. By bringing to clear consciousness what the obstacles are, where they lie, and where favouring influences are found, it is itself an organic member of the practical process of setting up and effecting ends. The 'relation' is thus a statement of how to employ one part or phase of experience in regard to another.

It is a matter of method of action, not of structure of existence, physical or metaphysical.

Historical. As will be obvious from the preceding statements, the essential philosophical problem involved in the discussion of 'relation' is the connection between the logical process of knowledge (and knowledge is knowledge only in so far as it is logical) and the ontological order of reality. It thus occupies the same position in modern thought as was held by the mediaeval genus and species as the successor of the Platonic *idéa* and the Aristotelian *εἶδος*. Locke was chiefly instrumental in effecting the transition. He defined knowledge as 'nothing but the perception of the connection of and agreement or

disagreement of and repugnance of our ideas' (*Essay*, Bk. IV. chap. i). Nominally, he does not define this agreement or disagreement as relation; but he expressly says that relation is one form of knowledge, and that of the three forms, two, viz. identity and coexistence, are only peculiar forms of relation. The fourth kind, 'knowledge of real existence,' brings us to such propositions as God is, and the existence of things. The former depends upon the relation of causation, and the latter upon some assurance or belief regarding the relation of immediate sensation to some object to which it corresponds, for practical purposes at least. Hence relation is, directly or indirectly, the central thing in knowledge. Berkeley only needed to make explicit this fact to make it evident that since one of the terms could not by any possibility be an idea, it was perfectly meaningless. Thus the problem of 'knowledge of real existence' became a problem of some valid sort of relationship between our 'ideas' or experiences, not of an 'idea' to something beyond all experience. Hume made explicit this problem, expressly sought for any relationship which could assure valid reference of the terms of experience to one another, and distinctly criticized all candidates that offered themselves. He showed that the worth, for cognitive purposes, of all relations came back to that of causality. He followed out the logic of Locke's statement that relation is the result of comparison, of a mental operation (Locke's *Essay*, Bk. II. chap. xxv. § 1), to prove that in itself every distinct idea is a *separate* existence, and to show that causality (or any relation) cannot affect reality itself, and hence must have a purely subjective origin—which he found in the power of imagination to glide easily from one idea to another frequently associated with it (see Bk. I, Part III, of *Treatise upon Human Nature*). It is well known how this scepticism 'awakened' Kant to a reconsideration of relations and their place in knowledge, and led him to redefine judgment as a necessary synthesis of sensations through concepts of the understanding, instead of as their casual association. The relations termed CATEGORIES (q. v.) by Kant and his successors are then the necessary, universal, and hence *a priori* (inherent in thought itself) functions of judgment in construing a world of experience (see the transcendental analytic in Kant's *Critique of Pure Reason*). The stone which Hume rejected became the corner-stone

of modern epistemological idealism. Kant derived his table of twelve categories from a mere inventory of the forms of judgment recognized in formal logic. His successors took the idea of their being necessary modes of thought more seriously, and endeavoured to show how thought inevitably shows itself in such and such a system of relations. Fichte's *Wissenschaftslehre* and Hegel's *Logik* are the results. After Hegel's time the current divided into two streams: one the logical proper, attempting a more empirical and detached investigation of all the various relations or categories employed in judgment, e.g. number, quality, thing and attribute, &c., and the other the metaphysical, concerning itself with the objective validity of relation and hence of thought. (J.D.)

Relations considered as objective are variously classified. Some of the principal headings usually recognized are relations of Dependence (logical, see REASONING, and CONSEQUENT; causal, see CAUSE AND EFFECT); WHOLE AND PART (q. v., see also QUANTITY); QUALITY (q. v., see also CONTRAST, various topics); Temporal (see TIME); Special (see SPACE). Relations are also distinguished as 'dynamic' and 'static,' according as they do or do not involve process and change. For relation considered as CATEGORY see that term, and also PREDICAMENT. Cf. also RELATIVITY (different topics), and RELATIVE AND ABSOLUTE. (J.M.B.)

Literature: as will be inferred from this summary sketch, the discussion of relation is rather to be gathered in the whole drift of any modern writing upon metaphysics, than located in any one passage; but the following additional references may be of some value: HAMILTON, *Lects. on Met.*, ii. 535-8; *Discussions*, 603-8; REID, on Intellectual Powers, *Essay VI. chap. i*; MILL, *Logic*, Bk. I. chap. ii. § 7, and chap. iii. §§ 10 and 11; LOTZE, *Logic*, § 337-8; *Metaphysic*, § 80-4; GREEN, *Prolegomena to Ethics*, Bk. I, and the whole course of his criticism of Locke, Berkeley, and Hume (*Works*, i); BRADLEY, *Appearance and Reality*, Bk. I, especially chap. iii; BOSANQUET, *Knowledge and Reality*. Discussion upon the psychology of relations is inadequate. The following may be noted: SPENCER, *Princ. of Psychol.*, § 65; JAMES, *Psychology*, i. chap. ix (especially 243-71) and ii. 663-75; STOUT, *Analytic Psychol.*, Bk. I. chap. iii; LOTZE, *Metaphysic*, Bk. III. chap. iii. The general tenor of the more recent discussion from the psychological

side is distinctly 'pragmatic' in its direction—to find the reality of relation in the inherent 'motor' tendency of any experience, and not in the structure of the sensation, in its casual associations, or in any separate 'relating' function. Cf. JAMES, *Will to Believe*, especially the *Essay on The Sentiment of Rationality*. (J.D.)

Relation (consciousness or apprehension of—which are better terms than 'sense,' or 'perception' of). When an attribute of an object *a* by its intrinsic nature also qualifies another object *b* in such wise that it cannot be conceived to exist apart from *b*, this attribute is said to be a relation between *a* and *b*; for consciousness of relation it is necessary not only that presented contents shall be related, but also that their relation shall itself be an object of consciousness.

The problem which is of chief interest to the psychologist is to assign the various grades of distinctness in which relations are apprehended. The mere union of parts in a total object does not involve consciousness of relation. The infant whose experience, according to James, is one 'buzzing, blooming confusion,' cannot be said to be aware of relations. With a single glance of the eye we may embrace in one field of view a vast variety of details. But we may have exceedingly little apprehension of interrelation of these details. To bring these relations to consciousness we must exercise analytic and synthetic attention. We must single out successively the separate constituents of the whole, and we must attend simultaneously to discriminated items, coupling them now in this way and now in that. Through processes of this kind consciousness of relation comes into being.

But the consciousness of relation thus attained need not involve a distinction between the relation as such and the things related. For this, comparison of relations is required and perhaps the use of language. We may be aware of *a* as distant from *b* without distinguishing the distance-relation as such from its particular presentation in this special case. It may merely form part of the presentation of this *a* and this *b* under these particular circumstances. If, however, we compare the distance between *a* and *b* with the distance between *c* and *d*, the concept of distance becomes disengaged from its special setting in particular instances, and appears as a distinct object of attention. Such relation-concepts become fixed and receive further

development through the analytic-synthetic function of language. (G.F.S.)

Relative (and **Absolute**): Ger. *relativ*; Fr. *relatif*; Ital. *relativo*. For the foreign equivalents for **ABSOLUTE** see that term.

I. *Relative*. The term 'relative' may be applied either to words or to things.

A. A 'relative' word or term is one which can be used as a predicate, to signify that the subject has a certain kind of relation to some other subject, which is not expressly mentioned. A relative term is thus primarily to be distinguished: (*a*) from words expressing relations, which can only be used as copulas, where both subjects, between which they express a relation, are mentioned; (*b*) from qualitative predicates, which express the kind of entity which is related to some subject, but not the kind of relation which it has to it. But further, since the significance of a relative term is not exhausted by the relation which it expresses, but may also give information with regard to the nature of the subjects which it relates, it must also be distinguished from (*c*) words expressing a relation, which cannot be predicated of either subject singly, but only of both conjointly.

When a relative term can be applied to one subject, any term which can be applied to the other, to express the fact that it has to the first the converse relation to that expressed by the relative term applied to the first, is said to be *correlative* to the original relative term.

B. As applied to things, 'relative' is never merely synonymous with 'related'; it is always distinguished therefrom by implying that the relation or relations to which it refers are *essential* to the subject of which it is predicated, i.e. that this subject is one which can only be defined by some property such as might be expressed by a relative term.

To say that a thing is relative is, therefore, always to contradict yourself, since it implies that the relation of a whole to something else is also identical with or a part of that whole; and the fact that relativity is a self-contradictory notion is sometimes expressly recognized by those who use it, while, even where this is not expressly recognized, it seems to be the source of the depreciatory significance usually attached to the term. The only relation in virtue of which a thing might, without contradiction, be called relative is that of a whole to its part; since to

affirm or deny the whole is to affirm or deny the part: but, in fact, a whole seems never to be called relative in virtue of this relation, and the term relative seems generally to imply that the relation itself, and not merely, as in this case, that to which it is related, is identical with or a part of that which is said to be relative. Thus it is always a part which is said to be relative, not to a part of itself but to another part of the same whole or to that whole itself, in the sense that it has thereto, or to the relation between them, that analytic relation which really holds between a whole and its part; and to say this is always self-contradictory. A thing is, however, generally said to be relative to another thing only if it has certain kinds of relation to that thing; and the term, therefore, perhaps generally signifies confusedly that it has one or more of these, not only that they are constituents of its essence. Hence 'relative' may be said to denote, not only the self-contradictory proposition that a thing 'has no meaning apart from' some relation, or 'would not be what it is but for' its relations, but also that it has some one of the relations which may be classed under the two following heads:—

(1) That we can only describe or identify it by mentioning its relation to something else. This is not the case with *qualia* or unique instances of *qualia*, but only with particulars, of which there are several exactly alike. In these cases, to say that a thing is 'relative' implies that it differs from some other solely in respect of some relation, i.e. where it really differs from it only numerically this numerical difference is denied; and, in this sense, 'relative' almost always has a depreciatory significance, i.e. implies that the thing in question is unreal. The following are the chief relations which are thus used to identify particulars:—

(a) The relation of a position in time to the unique event by which its date is fixed. This relation may be either that of the position occupied by such event to the event, or those of distance before or after such position—a distance the length of which can again only be specified by reference to the number of certain events supposed to recur at equal distances. The same is true of positions in space at any one moment, but more commonly—

(b) Spatial positions are said to be relative, in virtue of the fact that we cannot identify positions at two different times, except by their relation to those occupied at both times

by some other things, which are assumed either to occupy the same positions or to have moved continuously. Thus the relativity of motion and position signify, not merely, as with temporal position, that a position can only be identified by its relation to some unique thing, but that this unique thing itself will not serve to identify a position in every possible sense, since it must be assumed either to have been at rest or to have moved continuously, and we cannot tell either which has been the case or what has been the velocity of the movement, nor even that either has occurred.

(c) Exact similars occupying space and time may be said to be relative, in virtue of the fact that they can only be identified by reference to their occupation of positions which are relative either in sense (a) or in sense (b).

In view of the above facts, time and space as wholes are often said to be relative. This appears to be meant either (a) in the relative sense, dealt with below (2, a), namely, that they would be nothing apart from the things that occupy them, or (β) in the absolute sense, that they are composed of parts which are all relative and are therefore unreal; but it seems to be commonly implied that these parts are all relative to one another, and thus involve an infinite regress, through confusion of the position identified by its unique occupant with that occupant. Similarly matter may be said to be relative, because all its parts are relative to positions; and the same accusation may be extended to all that occupies space and time, because it is always composed of relative parts; which latter usage not only, like the others, involves neglect of the fact that the parts are relative not to one another, but to unique wholes, but also of the fact that these wholes are themselves occupants of space and time, and yet are not relative in any sense, since they can be identified without reference to their external relations.

(2) That a thing has some one of the following relations. These relations may belong to *qualia* or to unique instances of *qualia*; and hence when things are said to be relative in virtue of them, it is generally implied that the part of their essence which has the relation is distinguishable from the relation, but that it would not be so if it had not the relation. It is relations of this kind which are supposed to bind together the parts of so-called 'organic wholes,' which are defined as wholes of which the parts would not be what they are, but for

RELATIVE AND ABSOLUTE

their relation to one another and to the whole: hence 'relative,' in this sense, may be used as a term of praise, implying that a thing involves the kind of contradiction necessary to constitute it a part of reality.

(a) All simple *qualia* may be said to be relative, in the sense that they must have the relation of difference to something else: a doctrine which is sometimes expressed by the formula 'No identity without difference.' It is thus supposed to be a contradiction that a thing should be and yet be different from nothing, on the ground that it is inconceivable; by which is meant the supposed psychological laws (a) that it is impossible to think of only one thing at a time, (β) that it is impossible to think that a thing should not be different from something else, (γ) that it is impossible to identify a thing, without thinking both of something different and that they are different. In a similar confused sense it may be said that all relations are inconceivable, on the ground that they cannot be conceived apart from some two things which they relate; and hence that they are relative. So, too, space and time may be said to be inconceivable apart from some occupant.

(b) Two things may be said to be relative to one another, if they are united by any of the following necessary relations, viz. mathematical and logical relations other than that of whole to part, the relation of a class-concept to a member of its class, and the relation of cause to effect. It must be noted (a) that, though a member of a class or particular instance of such is always said to be relative to its class-concept, the latter is not generally said to be relative to all the members or to any particular member, but only to *some* member; (β) that the causal relation in virtue of which relativity is most frequently asserted, is that of agent and reagent, in which two things, permanent through time, and necessarily coexistent, are said to be causes of one another.

(c) A thing may be said to be relative to another, which is not relative to it, if it is conceived to be related to it as attribute or accident to SUBSTANCE (q. v.), or as appearance to reality (see RELATIVITY OF KNOWLEDGE, and REAL). A substance would sometimes be said to be relative to all its attributes, or to *some* accidents or attributes, but never to any particular attribute or accident; but sometimes it is conceived as absolute.

II. *Absolute*. A. All terms except (1) relative terms, (2) terms which can only be used as copulas to express a relation, may be said to

be absolute. Absolute is thus, with reference to relative, a negative term, denying that a term is of these two kinds.

B. Absolute may be used to deny that a thing is relative in any of the senses above defined. But the following are the commonest distinct uses:—

(1) It may be used of simple *qualia* to deny that their identity can be affected by the relations mentioned under I. B (2), as supposed to affect them.

(2) Absolute, as applied to position in space, seems not merely to be the contradictory of relativity, as defined in I. B (1, a and b), but to imply the possession of one or more properties, which would render the identification of positions by reference to their occupants unnecessary. The properties that may be thus implied are (a) that every position is numerically different from every other, (b) that each is qualitatively different from every other, (c) that a position may have a unique place in some qualitatively unique spatial series, in a sense in which this is impossible in Euclidean space, because such series are infinite. In this last sense absolute is also applied to magnitude, i.e. to signify a magnitude which should be the first or last in its series, and therefore need not be identified by reference to a unit, which in its turn is only identified by reference to something possessing the degree of magnitude intended. By 'absolute space and time' is not meant a space and time composed of absolute positions, but a space and time which, though relative in the senses given above, are either (a) not mere relations between the things that occupy them, or (b) not capable of accurate measurement by us, but such as geometry deals with.

(3) By an absolute existent is meant one whose existence does not depend upon that of any other, i.e. which is incapable of being produced or altered by any cause. But 'absolute' in this application seems generally to retain something of its etymological meaning = complete, i.e. what is logically incapable of being altered by addition, since it possesses every attribute of which it is capable. Hence, by those who hold that all relations argue incompleteness and dependence, 'the absolute' is used to denote that which is the whole of reality, and is incapable of alteration, because there is nothing external to it which could alter it.

History. The self-contradictory conception of things which could be defined by their relations, and even the recognition of this contradiction, date from the beginning of

philosophy; e. g. both are implied in the Platonic conception of *γινόμενα* and the Aristotelian of potential existence; but the name 'relativity,' as applied to this conception, together with its extremely wide application and the treatment of it as a fundamental principle, date only from the philosophy of Kant. Absolute, on the other hand, is connected with or used for the Aristotelian *ἐντελέχεια*, which denotes what is complete and independent in the peculiar Aristotelian sense of what has no potentiality unrealized—whose form is completely actualized; and this conception, applied to God in the middle ages as the absolute or most perfect Being, and persisting till Kant in this application, is thus directly connected with the Hegelian term 'The Absolute.' Absolute and relative, as contradictories, first became objects of controversy at the beginning of modern philosophy, in connection with the new science of dynamics and as applied to motion and hence to space: thus Newton and Clarke maintained that space was absolute in the senses, (1) that each position was numerically different from every other, (2) that it was not a mere adjective of things, but might exist independently, and both these propositions were denied by Leibnitz. Kant's philosophy was greatly influenced by his study of these questions concerning the philosophy of mathematics; and he is perhaps responsible for the vogue of the word 'relativity,' by the cardinal position which he assigns to the nature of space and time in this respect. He does not, however, himself use the word as a principal term; and those two conceptions of his, which have had the widest influence in obtaining recognition for relativity, have only an indirect connection with the relativity of space. These are (1) his doctrine that the objects of experience are all constituted such, not by being given data between which relations hold, but by the fact that they are related in certain definite ways, and (2) his doctrine that these objects, therefore, form an infinite series, to regard which as real would be self-contradictory. Of the use of the word 'relativity' these doctrines seem to have been the origin, chiefly through Sir William Hamilton, who applies the word broadcast and with the most extreme vagueness, so that it is impossible to discover, in any particular case, whether it has any or all of the meanings detailed above; and this habit has been adopted, to a less degree, by influential writers such as Bain and Spencer. This use of the word has been no less encouraged by the writers strongly influenced

by Hegel, who, though they do not use the word much, emphasize the conception even more; holding the doctrine that no relation is purely 'external,' i. e. fails to affect the essence of the things related, and that the more nearly it is external, the less real are the things it relates—a doctrine which they connect with the express contention that all the objects of experience are more or less self-contradictory.

See RELATIVITY OF KNOWLEDGE, and RELATION. (G.E.M.)

Relative (1) and (2) Absolute Ethics. A moral code or system of moral rules which (1) does or (2) does not vary with the different conditions of human life or at the different stages of its development. See ETHICS, and ETHICAL SYSTEMS.

The term absolute ethics was introduced by Spencer to signify the 'final permanent code' of conduct which describes the behaviour of fully evolved man in a fully evolved society. It implies, according to him, a condition in which the individual is perfectly adapted to his environment, and it excludes all cognizance of pain or of wrong. Absolute ethics is distinguished by Spencer (*Princ. of Eth.*, Part I, 'Data,' chap. xv) from relative ethics—the latter being regarded as an application of the former to a particular stage of development. The former might also be applied to such systems of ethics as regard moral laws as incapable of change or development—following eternally from the nature of God or of ultimate reality. To a system of this latter kind—called 'absolute' as opposed to 'relative' or 'conditional' morality—the title of Cudworth's treatise, 'eternal and immutable morality,' is commonly applied. (W.R.S.)

Relative Suggestion: not in use in the other languages. Associative reproduction so far as it is modified by the relatively new connections into which the revived presentations enter as parts of a train of thought. The term is used by Stout, *Analytic Psychol.*

The conception of associative reproduction as a REDINTEGRATION (q. v.) throws light on the meaning of relative suggestion. The term redintegration stands for the tendency of a presentation to reinstate the whole of which it has previously formed part. But in order to reconstitute the whole, not only the parts but their characteristic form of combination must be revived. If *a* is to reconstitute the whole *ab*, of which it has previously formed part, it is not enough for *a* to reproduce *b*; it must reproduce *b* in the same relation *r* to itself, as on the occasion of the original

experience. But the conditions operative at the time of reproduction may be such as to make unmodified reinstatement impossible. They may be such that if the parts are revived without alteration, their relation cannot be reinstated; or inversely, if the relation is reinstated, the related presentations must be modified. It may happen, and very commonly does happen, that the presentation which starts the reproductive process is not a mere repetition of the corresponding constituent of the original whole. It may vary considerably from this original constituent without losing its redintegrative tendency. Suppose the original combination to be ab , where a stands to b in a certain relation r . Suppose a to recur in the modified form a' . Inasmuch as a' partakes of the nature of a , it will tend as far as may be to reconstitute the whole ab . But the difference between a and a' may be such as to require a corresponding differentiation of b if the relation r is to be reinstated. It may happen that b cannot assume the same relation to a' as that in which it stood to a . Thus the revival of b will not be a reconstitution of the original whole, because the relation r has disappeared. On the other hand, if the relation r is recalled, the other term of the relation must be modified. For b there must be substituted β , which is related to a as b was related to a . This is relative suggestion.

What actually takes place on any given occasion depends on the special conditions operative at the time. The more fully and intensely we are interested in the whole as such, the stronger will be the tendency to revive the relation r and to modify b so as to transform it into β . This tendency may take effect at once, so that a immediately calls up β without the previous intervention of other mental processes. Thus in the very act of making a pun or a rhyme we may alter the pronunciation of a word. If we are looking for a place on a map which we know by actual travelling to be a certain distance from London, we allow for the difference in scale between the actual distance and that on the map without express comparison or explicit formulation. The imitative plays of children are full of such mental accommodations, the doll, for instance, being treated as a baby *mutatis mutandis*.

In such cases relative suggestion operates or may operate immediately, in others it does not take effect without an intervening mental operation involving express comparison between the present case and its analogue.

When this happens the process is one of reasoning in the proper sense. Suppose we have to throw a piece of paper upwards for a considerable distance. We are used to throwing stones as far or further; but a piece of paper is different. If the problem presented itself for the first time, it is very unlikely that any one but a genius would proceed immediately to wrap the paper round a pebble and then throw. There would be a previous comparison of the case of throwing a stone and throwing a piece of paper, and the relative suggestion would be brought to birth by the help of this preliminary process.

It will be seen that relative suggestion depends on the interest which a certain kind of relation or form of combination possesses. It would be possible to classify different types of mind from this point of view. In some minds rhetorical antithesis, in others metaphor, in others syllogistic form, in others a triple dialectic movement preponderates and determines relative suggestion. (G.F.S.)

Relatives (logic of): Ger. *logische Beziehungslehre*; Fr. *logique des relations* (L.C.); Ital. *termini relativi* (relative terms). If from any proposition having more than one subject (used to include 'objects') we strike out the indices of the subjects, as in '— praises — to —,' '— dat in matrimonium —,' what remains and requires at least two insertions of subject-nouns to make a proposition is a 'relative term,' or '*relative rhema*,' called briefly a 'relative.' The relative may be converted into a complete assertion by filling up the blanks with proper names or abstract nouns; this serves as a criterion.

But in such a relative there must be such an idea of the difference between the subjects to be applied that 'dat in matrimonium' shall be different from 'datur in matrimonium.' In order to free ourselves from the accidents of speech, we might represent the sentence by the following diagram :

Cinna— dat in matrimonium —Cossutiam

Caesari

or, as follows :

$$d_{ijk} \text{ (Cinna} = i, \text{ Cossutia} = j, \text{ Caesar} = k).$$

Then the relative will appear as

— dat in matrimonium —

or as

 d_{ijk}

But in either case, in order to explain what

RELATIVES

is meant, it will be necessary to explain how those three tails, or the three letters *i*, *j*, *k*, differ. The order shows which of three indices is given, which giver, which recipient.

Relatives may be more or less general like other terms, that is, one relative may be predicable of members of a set of which another is not, while the latter is predicable only of members of sets of which the former is predicable. By a set is meant an ordered system, so that *ABC* and *BCA*, though the same collection, are different sets. As any general term is predicable of any one of an aggregate of individuals, so a relative is predicable of any one of an aggregate of sets; and each such set may be regarded as an individual relative. By a system is meant an individual of which if anything is true, the truth of it consists in certain things being true of certain other individuals, called its *members*, regardless of the system. A *system* is either a *sorite*, *heap*, or *mere collection*, or it is a *set*. A *sorite* is a system of which, if anything is true, its truth consists of the truth of one predicate for any one of the members. A *set* is a system of which the truth of anything consists in the truth of different predicates. Of course the idea of relation is involved in the idea of a system. As it is very important for the understanding of relations that the conception of a system should be perfectly clear, let us consider the latter a moment in its simplest form, that of a *sorite* or mere collection. *ABC* is a sorite. Thus, it is true of it that it contains the three first letters of the alphabet, and the truth of that consists in *A*, *B*, and *C* being each one of the first three letters of the alphabet. It is true that it contains nothing but the first letters of the alphabet, because it is true of *A*, *B*, *C* severally that each is nothing but one of the first three letters of the alphabet. *AB* is a different sorite, because something is true of it which is not true of *ABC*. *A* may be regarded as a sorite provided we mean not *A* in its first intention and being, but a something whose being consists in *A*'s being. The collection *A* is not the letter *A*, but it contains *A* and nothing else. If it be said that there is no such thing, the reply is that every collection, every system may be said to be an *ens rationis*. To this point we shall return. Even Nothing may be said to be a collection. For when we say that Nothing is less than 1, we do not mean that a self-subsisting individual is so, but that an *ens rationis* whose mode of

being consists in the absence of everything is less than 1. The sorite *ABC* is other than *ABT*. But should I say that *ABC* contains two of the letters of Caesar's first name, and subsequently learn that that was a mistake, the real name being Gaius, that would not make *ABC* a different sorite.

That in the reality which corresponds to a proposition with a relative predicate is called the *fundamentum relationis*. A *relationship* is a system of such fundamenta. *Relation* is the relative character, conceived as belonging in different ways to the different relates, and (owing to the somewhat undue prominence given by familiar languages to one of these) especially to the relate which is denoted by the noun which is the subject nominative.

Relatives and relations are said to differ in their *orders*, according to the numbers of their relates. *Dyadic* or *dual* relations, or relatives of two relates, of which the second is called the *correlate*, differ somewhat widely from *plural*, or *polyadic*, relations. *Triadic* relations have all the principal characters of *tetradic* and higher relations. In fact, a compound of two triadic relatives may be a tetradic relative; as 'praiser of — to a maligner of — to —'.

Relatives may be compounded in all the ways in which other terms can be compounded as well as in other ways closely related to those. Thus, *A* may be said to be at once a lover and a servant of *B*, and it may be said that there is something, *X*, such that *A* is a lover of *X*, while *X* is a servant of *B*; so that *A* is a lover of a servant of *B*. This mode of composition is called *relative multiplication*. So, not only may it be said that *A* is either a lover or a servant of *B* (not excluding both), but also that whatever *X* may be, either *A* is a lover of *X* or *X* is a servant of *B*; that is, *A* is a lover of everything there is besides servants of *B*. (This wording, by Schröder, slightly violates English idiom, but is valuable as showing the analogy to aggregation.) This mode of composition is called *relative addition*. So, again, it may not only be said that *A* is if a lover then a servant of *B*, but also that whatever *X* may be, if *A* is a lover of *X*, then *X* is a servant of *B*; that is, *A* is a lover only of servants of *B*. This is called *relative regressive involution*. Or it may be said that whatever *X* may be, *A* is a lover of *X*, if *X* is a servant of *B*, or *A* is a lover of whatever is a servant of *B*. This

is called *relative progressive involution*. Polyadic relatives are capable of other modes of composition. Thus, it may be said that anything whatever, X , being taken, something Y exists, such that A praises X to Y while X maligns Y to B ; that is, A praises everybody to somebody malignd by him to B . Or we can say that there is something Y , such that, whatever X may be, A praises X to Y while X maligns Y to B ; or, A praises everybody to somebody whom everybody maligns to B .

Deductive logic can really not be understood without the study of the logic of relatives, which corrects innumerable serious errors into which not merely logicians, but people who never opened a logic-book, fall from confining their attention to non-relative logic. One such error is that demonstrative reasoning is something altogether unlike observation. But the intricate forms of inference of relative logic call for such studied scrutiny of the representations of the facts, which representations are of an *iconic* kind, in that they represent relations in the fact by analogous relations in the representation, that we cannot fail to remark that it is by *observation* of diagrams that the reasoning proceeds in such cases. We successively simplify them and are always able to remark that such observation is required, and that it is even thus, and no otherwise, that the conclusion of a simple syllogism is seen to follow from its premises. Again, non-relative logic has given logicians the idea that deductive inference was a following out of a rigid rule, so that machines have been constructed to draw conclusions. But this conception is not borne out by relative logic. People commonly talk of the conclusion from a pair of premises, as if there were but one inference to be drawn. But relative logic shows that from any proposition whatever, without a second, an endless series of necessary consequences can be deduced; and it very frequently happens that a number of distinct lines of inference may be taken, none leading into another. That this must be the case is indeed evident without going into the logic of relatives, from the vast multitude of theorems deducible from the few incomplex premises of the theory of numbers. But ordinary logic has nothing but a barren sorites to explain how this can be. Since Kant, especially, it has been customary to say that deduction only elicits what was implicitly thought in the premises; and the famous distinction of analytical and syn-

thetical judgments is based upon that notion. But the logic of relatives shows that this is not the case in any other sense than one which reduces it to an empty form of words. Matter entirely foreign to the premises may appear in the conclusion. Moreover, so far is it from being true, as Kant would have it, that all reasoning is reasoning in *Barbara*, that that inference itself is discovered by the microscope of relatives to be resolvable into more than half a dozen distinct steps. In minor points the doctrines of ordinary logic are so constantly modified or reversed that it is no exaggeration to say that deductive logic is completely metamorphosed by the study of relatives.

One branch of deductive logic, of which from the nature of things ordinary logic could give no satisfactory account, relates to the vitally important matter of abstraction. Indeed, the student of ordinary logic naturally regards abstraction, or the passage from 'the rose smells sweet' to 'the rose has perfume,' to be a quasi-grammatical matter, calling for little or no notice from the logician. The fact is, however, that almost every great step in mathematical reasoning derives its importance from the fact that it involves an abstraction. For by means of abstraction the transitory elements of thought, the *ἔπεα πτερόεντα*, are made substantive elements, as James terms them, *ἔπεα ἀπτερόεντα*. It thus becomes possible to study their relations and to apply to these relations discoveries already made respecting analogous relations. In this way, for example, operations become themselves the subjects of operations.

To take a most elementary example—from the idea of a particle moving, we pass to the idea of a particle describing a line. This line is then thought as moving, and so as generating a surface; and so the relations of surfaces become the subject of thought. An abstraction is an *ens rationis* whose being consists in the truth of an ordinary predication. A *collection*, or *system*, is an abstraction or abstract *ens*; and thus the whole doctrine of number is founded on the operation of abstraction. If we conceive an object to be a collective whole, but to be so in such a way that it has no part which is not itself a collective whole in the same way, then, if the collection is of the nature of a sorite, it is a *general*, whose parts are distinguished merely as having additional characters; but if the collection is a *set*, whose members have other relations to one another, it is a *continuum*.

The logic of continua is the most important branch of the logic of relatives, and mathematics, especially geometrical topic, or topical geometry, has its development retarded from the lack of a developed logic of continua.

Literature: relatives have, since Aristotle, been a recognized topic of logic. The first germ of the modern doctrine appears in a somewhat trivial remark of ROBERT LESLIE ELLIS. DE MORGAN did the first systematic work in his fourth memoir on the syllogism in 1860 (Cambridge Philos. Trans., x, 231-358); he here sketched out the theory of dyadic relations. C. S. PEIRCE, in 1870, extended Boole's algebra so as to apply to them, and after many attempts produced a good general algebra of logic, together with another algebra specially adapted to dyadic relations (Studies in Logic, by members of the Johns Hopkins University, 1883, Note B, 187-203). SCHRÖDER developed the last in a systematic manner (which brought out its glaring defect of involving hundreds of merely formal theorems without any significance, and some of them quite difficult) in the third volume of his *Exakte Logik* (1895). SCHRÖDER's work contains much else of great value. PEIRCE has published only three papers since 1883, one of which appeared in the Amer. J. of Math., vii. (1885) 180-202, and the other two in the *Monist*, vii. (1896-7) 19-40, 161-217. An important work in which relations are treated graphically is A. B. KEMPE's *Theory of Mathematical Form*, published in the Philos. Trans. for 1890. Other workers are JOSEPH JOHN MURPHY, ALEXANDER MACFARLANE, GIUSEPPE PEANO. GEORG CANTOR, RICHARD DEDEKIND, and others have treated relations of quantity, and their writings—especially DEDEKIND's book, *Essays on the Theory of Number* (Eng. trans., 1901)—are particularly recommended to students of philosophy. Translations of parts of some of CANTOR's memoirs into most puzzling French are given in the *Acta Mathematica*, ii; the *Math. Annalen* (xli and xlix) contain others of great importance; and CANTOR especially addresses students of philosophy in his *Zur Lehre vom Transfiniten Erste Abth.*, (1890). This brochure consists of papers originally printed in the *Zeitsch. f. Philos. u. philos. Krit.* See also V. B. RUSSELL, *Sur la logique des relations*, in *Revue de Mathématiques*, vii (1901); WHITEHEAD, in recent numbers of the Amer. J. of Math. (C.S.P.)

Relativity: Ger. *Relativität*; Fr. *relativité*; Ital. *relatività*. That element in the

determination of a thing or object which arises from its RELATION (q.v.) to other things or objects. See the following topics. (J.M.B.)

Relativity (affective). The liability of affective states to modification by other affective states.

Applied (1) to pleasure and pain, which are said to be relative to each other; an extreme form, holding that pleasure is only absence of pain (cf. the literature of PAIN AND PLEASURE, the 'relativity theory'); (2) to emotions, considered as liable to modification from one another. See CONTRAST (affective). (J.M.B.)

Relativity (in psychology, law of): Ger. *Beziehungsgesetz, Gesetz der Relativität*; Fr. *loi de relativité*; Ital. *legge di relazione (or relatività)*. (1) The law that every phase of experience is influenced by every other phase of the experience of the moment, and also by the whole past history of consciousness.

It is employed by Wundt to explain Weber's law, certain geometrical optical illusions, visual contrast, temperature adaptation, &c. Experimental psychology has, however, in general preferred to look to physiology for the conditions of such mental facts or laws (Wundt, *Physiol. Psychol.*, 4th ed., i. 393, 397, 416, 591; *Human and Animal Psychol.*, 62, 119, 264). In Wundt's *Grundriss* (1896) the law of relativity assumes a threefold form: the law of psychical resultants, the law of relations, and the law of psychical contrasts. This theory is known as that of the 'relativity of sense qualities.' Cf. CONTRAST (various topics). (E.B.T.)

(2) The theory defined under RELATIVITY OF KNOWLEDGE (2).

Relativity of Knowledge: Ger. (1) *Relativismus*, (2) *Relativität der Erkenntnis*; Fr. *relativité de la connaissance*; Ital. *relatività della conoscenza*. (1) This term seems most properly to denote the theory that all human knowledge is relative to the human mind, in the sense that we can only know, of things, the effects which they produce upon our minds, and not what they themselves are like. Cf. EPISTEMOLOGY.

The theory is thus, as it stands, doubly self-contradictory, since it combines the proposition (a) that each of us can know nothing but what is in his own mind, whence it follows that he cannot know that anything but his own mind exists; with the propositions (b) that we do know that what is in our minds is an effect of other things; and (c) that this is true of us, i.e. that more than one

human mind does exist. Moreover, proposition (a) seems to be intended to assert that we do know the states of our own minds absolutely, i.e. that all the knowledge, which on this theory we can have, is absolute; and hence, on pain of a further contradiction, it would seem that the relativity of all our knowledge must be understood to mean merely that it is limited to a certain class of objects. That relativity should be understood in this sense does not, however, seem to be the intention of those who hold the theory; if it were so, the inclusion in its definition of proposition (b) would be a perfectly evident contradiction. Their meaning seems rather to be that, knowledge being a mere effect produced in our minds by the things which are known, we cannot tell whether it resembles them or not; and hence that, since knowledge of a thing is always knowledge not of it, but of its effect on us, all our knowledge may be not knowledge, but false belief. They seem merely to have overlooked the fact that this theory is openly self-contradictory; and that, if it were true that doubt must be cast on our knowledge of things, on the ground that it is a mere effect, the same doubt must also consistently be cast on our knowledge of these effects, i.e. on our knowledge of what is in our minds. Such inconsistencies must follow from their fundamental false assumption that to be known is to produce an effect upon the mind, i.e. that the relation of knower to known is a causal relation; for it immediately follows from this that we never do know what we know, but always something else, which is to be regarded as a result of the interaction with our minds of the object we alter by knowing it.

(2) The term has also been used to denote a psychological theory that we can never have knowledge of one thing only, but that whenever we are conscious of one thing we must also simultaneously be conscious of another different from and hence related to the first [see Hobbes, *Elem. Philos.*, iv. 25, 5; Bain, *Ment. and Mor. Sci.* (1868), 83; Ward, *Encyc. Brit.*, art. 'Psychology'; Höffding, *Outlines of Psychol.* It is criticized in Baldwin, *Handb. of Psychol.*, i.—E.B.T.]. Cf. RELATIVITY.

The term is now commonly applied to the theory of Protagoras, expressed in the famous saying, πάντων χρημάτων μέτρον ἄνθρωπος, 'man is the measure of all things.' This theory seems to have been based on the obvious fact that the same object may appear different to different men at the same time, or to the same

man at different times. It is from this fact that Protagoras appears to have drawn the contradictory conclusion that all our beliefs may be not partially, but wholly untrue, as is implied in his stating his theory with regard to all things. Both he and the Sceptics, who held a similar theory later, seem to have differed from modern relativists, chiefly in emphasizing the fact that some beliefs were false owing to changes in our minds, as their reason for holding that all might be false, and in not insisting that any of our beliefs were knowledge—a contradiction which they nevertheless implied. In modern philosophy definition (1) will apply to the theory of Kant, to which accordingly Mill applies the term, although neither Kant himself nor most others commonly so apply it. Kant held not only that all our knowledge is due to the interaction of our minds with external objects, but also that we can definitely trace what elements in it are due to each source. It was from him that Hamilton largely derived the theory to which he gave this name; a theory which seems capable of being brought under our definition, in spite of Mill's opinion to the contrary, if we understand him to have used 'object' in the same twofold sense as Kant, to denote (1) the thing-in-itself, (2) the object extended in space, which, though still relative to our minds, he holds to be an object whose qualities are directly perceived, whereas the secondary qualities are not intrinsic qualities of any object. Mill himself seems to hold that the above is the proper definition of the doctrine; but he fails to distinguish the importance of the question whether proposition (b) is or is not to be regarded as forming part of the definition along with (a) and (c), and accordingly he himself seems inclined to hold (a) and (c) alone, while still professing himself a believer in the relativity of knowledge, which he has defined as including (b). Bain uses the term to denote the psychological theory. Spencer upholds the 'relativity of knowledge' in a very vague and wide sense, seeming to identify Hamilton's doctrine, first, with the psychological theory (2), combined with a proposition contradictory of it, that we can only know relations and not the things related; and second, with the theory that everything we can know has some kind of relation to everything else. In similar vague senses the term may be applied to so many theories that details are unnecessary.

Literature: SIR W. HAMILTON, *Discussions*

RELIGION

on Philos. and Lit.; J. S. MILL, Exam. of Hamilton; H. SPENCER, First Princ.; A. BAIN, Logic. See EISLER, Wörterb. d. philos. Begriffe, 'Relativismus,' 'Relativität.' (G.E.M.)

Religion [Lat. *religio*, from *religare*, to bind]: Ger. *Religion*; Fr. *religion*; Ital. *religione*. Subjectively, the experience which arises out of man's conscious relation to some transcendent agent or agents, upon whose attitude towards him his welfare is believed in some measure to depend; objectively, the body of beliefs and practices which arise in connection with this experience, and which are ordinarily associated with some form of institutional life.

The above is a definition of the concrete experience of religion rather than a theory of it. Among the important questions that arise concerning religions are those of origin, development, and classification, the problems arising out of the comparative study of religions, and the philosophical question as to the ultimate nature and grounds of religion. This last-named question belongs to the philosophy of RELIGION (q.v.). The question of the origin of religion has its psychological aspect, in which the point in debate is whether religion is to be regarded as a superinduction or as being internally rooted in our nature (see RELIGION, psychology of); while objectively the issue arises between supernaturalism and naturalism, the latter presenting such forms as the dream theory of Herbert Spencer, the ghost theory of Tylor, or the view of Max Müller to the effect that religion has its origin in our sense of the indefinite. On the question of the development of religion there is (1) the problem as to the priority as between polytheistic forms of religion and monotheism, or, more strictly speaking, henotheism; (2) that of the place of fetichism, whether it is to be regarded with Tiele as a form of primitive animism, or, with Müller and Spencer, as a later and degraded form of religious belief. A fundamental distinction in the sphere of classification is that between the naturalistic and the ethical, the latter including all the higher and more spiritual forms. Certain of these problems are treated under the topics immediately following.

Religion (evolution of). (1) The historical stages of religion objectively considered in its relation to all other factors of human evolution and in all its embodiments and manifestations. (2) The science which treats of (1). (J.M.B.)

In the present state of knowledge, it is by no means easy to speak either with definiteness or decision on this subject. Several reasons may be assigned. (1) There can be no competent treatment of evolution of religion apart from a science of religions; and this science has come into being only within the last fifty years. (2) The history of religions has made such enormous progress within living memory that the materials garnered have not been mastered fully as yet. (3) The fundamental principles, rational and natural, to which evolution must be traced, were not recognized as present in all religions till within comparatively recent times. Vico (1725), Voltaire (1756), and Lessing, in the well-known tractate on the *Education of the Human Race* (1780), adumbrated the modern standpoint. Nevertheless, till this time—and till a much later date among the English-speaking peoples (see *Bridgewater Treatises*)—natural theology, with certain crass metaphysical implications, everywhere held the field, making an application of the historical, comparative, and genetic methods out of the question. Herder (1784) first formulated specifically something like the evolution problem; but it was reserved for Hegel (1829) to give the requisite vitality to the new conception of the unity of religions—to recognize religion in them all. Indeed, systematic treatment of the entire subject-matter, undertaken with complete consciousness of aim, was possible only so late as 1860, and did not make marked progress, nor attract general attention, for another decade. (4) Evolution, too, is a comparatively new discovery; for although it was held by men of culture as early as the middle of the 18th century, and by philosophers early in the 19th, its main exploitation belongs to the biologists after the middle of the latter. Naturally, then, many problems still remain to be elucidated ere one can declare precisely how a theory of the transformation of organisms can be transferred, with sufficient justification, to material so widely different as religion. It may be

well to remark, in passing, that notable success in the accumulation of mere facts has served to obscure this point hitherto, and to an unfortunate degree. As in biology, so here, discussion of certain aspects of the means whereby evolution takes place has often been mistaken for a controversy over evolution itself—a totally different thing.

The principal difficulty in applying evolution to religion must be traced to the facts that evolution is a complex conception, and that we are as yet far from being masters of the various implied elements. What are they? The application of evolution to religion implies (1) the assembling or collection of all accessible data regarding religions; that is, it cannot be accomplished without a competent history of religions. (2) When the data have been thus procured, it is necessary to treat them scientifically. They must be grouped; and here the methods of comparison, with their ancillaries of likeness and difference, have to be employed. On this basis alone can inductions be made with safety. In other words, application of evolution to religion requires a science of religions. (3) Finally, on the basis of the results obtained from this history and science, deduction becomes possible, and then the sphere of philosophy of religion is entered upon. Here, too, the problem of evolution assumes its acutest form. But it is highly undesirable, as past efforts show, even if it were feasible, to separate history and science of religions from philosophy of religion in dealing with this subject. For the most important aspects of the problem demand continuously the presence of all these disciplines, especially of the science and the philosophy. This becomes evident when it is remembered that the conception of evolution contains two co-operating ideas, neither of which can be torn from the other. These are the ideas of change and of permanence. Taking the changes incident to an evolution of religion, we at once encounter problems which, though trenching upon philosophy, belong conspicuously to the sphere of science of religions. For example: What are the species of religions; that is, what stages can be traced in the evolving series? Seeing that all religion is teleological, are any marked differences of aim to be found as between the various species? What are the laws of the evolution; or, do beginnings, growth, maturity, and decay, in the various stages, follow similar or identical courses? How do the stages pass over into one another? In dealing

with such questions, the element of change predominates. When the element of permanence attracts attention, philosophy of religion comes to our aid. For such philosophical questions as the following must be asked. What is religion? What is the origin of religion? What are the psychological factors in religion? What is the differentiating factor or factors in human experience that make man a religious being, as no other being is religious? What is God?

It is necessary to remember that, philosophically speaking, evolution does not necessarily imply progress. The problem is to disengage a permanent element, common to all the changes, by the presence of which these changes, no matter what their differences, can be called *religious*. The permanent is to be deduced from the passing, the constitutive from the contingent. When this has been accomplished, it may be possible to display an evolution, in the sense that rational (that is, explanatory or self-explanatory) factors pertain to every stage. Then the special or distinctive task of philosophy begins to set forth an evolution, *not as a time series*, but as a gradual expansion in adequacy of explanation from type to type. Religion evolves in the sense that, as it becomes more and more sufficient to the conceptions of deity, of the universe as God's cosmos, and of the measure of perfect manhood, it also becomes more adequate to itself—that is, shows forth its own nature in progressively clarified shapes. Thus, at last, it becomes possible to interpret all religions in the light of religion (which is the highest religion), and to elucidate the constituent factors necessarily present in this last.

Numerous efforts towards this end have been made during the past eighty years. But we cannot anticipate an immediate or easy solution of the problems involved. This mainly because philosophy of religion is not yet a century old, while history and science of religions have been pursued for but two generations. Cf. the other topics RELIGION.

Literature: this is very large, and may be found at length in DE LA SAUSSAYE, *Lehrb. d. Religionsgesch.* In the list which follows, the Hibbert and Gifford Lectures more important for the present subject are italicized. Hibbert Lectures (*Max Müller, Renouf, Renan, Rhys Davids, Kuenen, Beard, Réville, Pfeiderer, Rhys, Sayce, Hatch, d'Alviella, Montefiore, Upton, Drummond*); Gifford

Lectures (*Max Müller*, Wallace, J. Caird, Bruce, Stirling, Pfeiderer, Fraser, Tiele, E. Caird, A. Lang, L. Campbell, Ward, Tylor, Royce); D'ALVIELLA, Contemporary Evolution of Religious Thought; E. v. HARTMANN, Das religiöse Bewusstsein d. Menschheit; JEVONS, Introd. to the Hist. of Religion; RÉVILLE, Prolegomena to the Hist. of Religions (Eng. trans.); Les Religions des Peuples non-civilisés; RENOUVIER, Introd. à la Philos. analytique de l'Histoire; MAX MÜLLER, Introd. to the Sci. of Religion; TIELE, Outline of Hist. of Ancient Religions (Eng. trans.); HAPPEL, Das Christenthum u. d. heutige vergleichende Religionsgesch.; Die Anlage d. Menschen z. Religion; RAUWENHOFF, Wijsbegeerte v. d. Godsdienst; SCHULTZE, Der Fetischismus; TIELE, art. Religions, in Encyc. Brit.; and many arts. in the Rev. de l'Hist. des Religions; Theologische Tijdschrift; Annales du Musée Guimet; Wiener Zeitsch. f. d. Kunde d. Morgenlandes; Zeitsch. d. Deutschen Morgenländischen Gesell. (R.M.W.)

Religion (philosophy of): Ger. *Religionsphilosophie*; Fr. *philosophie de la religion*; Ital. *filosofia della religione*. The subject must be distinguished (see below) on the one hand from the science, history, or natural history of religion, on the other hand from theology. As a subject *eo nomine* it has a brief and definite history (see below), and may be defined as the study of the religious consciousness as an expression of ultimate reality. Cf. RELIGION (preceding topics).

The history, science, or 'natural history of religion' (Hume) professedly confines itself to the comparative study of religions as phenomena of human action, with reference to the causes of their origin and the laws of their growth. It supplies, however, an element of breadth and continuity, in the absence of which the philosophy of religion suffers loss.

Theology, on the other hand, professes to deal with the ultimate real basis of religious aspiration, but is usually in truth a formulation of the postulates involved in some one of the great historical forms of ritual and belief, so that we speak of Anglican and Catholic theology; it fails, therefore, to deal with the universal and necessary nature and foundations of the religious attitude as such. Natural theology, indeed, the idea of which comes to us through St. Augustine from the Stoic thinkers, and which ought not to be confined, as in the 18th century physico-theology, to the 'argument from design,' has tended from the beginning to keep open a larger outlook

on the world. The first definite attempt in Western literature to lay down 'canons of theology' was made by Plato, though what he meant by this expression was rules for imaginative art in its treatment of the divine nature. These were to the effect that God is not the author of evil, and is incapable of change and deceit. It should also be noted that the philosophy of religion, which is universal in its scope, is yet indebted to the Christian theology for very important ideas and principles. See below on the Ontological Proof.

Hume's *Natural History of Religion* (1757), superficial as it must appear from the standpoint of later knowledge, yet served as a protest against the narrower tendencies of the natural theology of the day, and was a starting-point both for the scientific history and for the philosophy of religion, by its appeal to inherent needs and tendencies of human nature as the ineradicable germ of the religious impulse. The Voltairean criticism, indeed, of the same period probably did much to make religion a generic name for one whole side of human faith and feeling, and thereby to give the subject a status among universal problems which later received a more serious treatment. The actual history of the term 'religion,' and of the time and context in which it or any such word first became a term of general application to the faiths and rituals of the world, would be an interesting chapter in the development of the human mind. Even Herodotus has some such general notion before him when he treats it as a proof of insanity to insult the sacred ordinances (*νόματα*) of any people. Understanding that the substantive problem of the philosophy of religion, being inseparable from the general theory of reality, had been more or less directly treated by all great philosophers (notably by Plato and Spinoza), we may nevertheless attribute the distinctively modern preoccupation with the philosophy of religion *eo nomine* to the impulse communicated by Kant under the influence of Rousseau, and to the augmentation of historical material which also stimulated the science and history of religion. The outcome of Kant's critical researches, with their apparently negative result, in the whole romantic and idealistic movement, is a well-known chapter of the history of philosophy. By showing that there were certain greatest matters of life which could not be found among the objects of perceptive experience, he put men upon thinking of them rather as

the law and unity of our whole world than as certain phenomena among others that are contained in it. In the generations that followed him, these conceptions were fused with a mass of archaeological and anthropological knowledge which had long been gathering, and which historical circumstances contributed to enlarge; and under the banner of romanticism in literature and philosophy, a new interest arose in plastic art, in poetry, and in religion, as expressions of the spiritual life of mankind. In the first place, it should be noted that from this time forward, as the sacred books of various nations became accessible and progress was made in the art of personally investigating the religions of undeveloped races, the scientific history of religion, with its kindred anthropological inquiries, has been embodied in an increasing literature, of which the most valuable part is the most recent (see citations below). On this ground of science and history, after many aberrations, and as a result of immensely intricate researches, a consensus appears to be manifesting itself to the effect that from the beginning religion displays itself as a social phenomenon, depending on a sense of union or communion between a group of human beings and their god, cemented in early times by a social meal in which the god, himself a natural object, and yet regarded as a member of the group, is actually consumed by the other members in order that entering into their body and soul he may renew their life, which is one with his own. It is held that the other and very complex forms of sacrifice known to history are later developments of a primitive form such as this. Magic thus appears as the anti-social form of religion; the setting up of a private relation to powers other than, or in other ways than, those known to and utilized by the community. It is on this question of the contrast between magic and religion that the language and perhaps the ideas of Hegel have proved least in harmony with the researches of science. Thus early religion is one with social ritual, and pervades the whole of life. 'Religion is intimately wrapped up with the tillage of the fields, the pasture of the flocks, the rules and modes of wedlock, the customs of the market, with sanitary rules, with the treatment of disease' (W. Wallace, *Lects. and Essays*, 162). Something of this kind appears to be the central result which the scientific history of religion is tending to establish. It should be noted that the worship

of deceased ancestors is not now held to have the importance, in the development of religion, which Spencer's theory assigned to it. Necessarily, this mode of treatment has less in proportion to say of the great religious systems which have been the occasions of a vast intellectual and imaginative activity, though here, too, the ritual and the popular faith remain, and demand investigation.

While the most valuable literature of the scientific history of religion is the work of the last thirty years, a substantially just account of the philosophy of religion would give primary rank to Plato, and include the deepest speculations of the greatest philosophers of the world. And even if we confine our account to the philosophy of religion *eo nomine*, which has flourished mainly since Kant, the greatest names in our history would be those of Kant himself, of Schelling, Hegel, and Schleiermacher, who are not to be found in the literature lists of the science and history of religion. Such an account would not be feasible within the limits of an article, and would moreover have to explain away a certain amount of historical misapprehension in the earlier thinkers due to the imperfection of the materials at their disposal. It will be best to state briefly the more important points of view which appear to be asserting themselves at the present day in the idealistic philosophy of religion, for, as distinct from the natural history of religion, there can hardly be said to be any other.

(1) We ask, how much do we include under the religious consciousness? Is it to be confined to a consciousness of God, or of the supernatural; or are the essentials of it to be found in states of mind which bear no explicit reference to what we should call God or to a supernatural world? Considering the variety of contents and purposes which are covered by the ideas in question, it seems impossible to make their shadowy common element the sole criterion of the religious consciousness, when other contents and purposes are found to play practically the same part in the actual experience of the human mind. The love of a person, or devotion to an idea, may apparently produce the peculiar religious effect, the effect of something which is at once an overmastering law of life and a source of strength outside our everyday being. This sense of loyal observance, of a rule in view of which we are moved at once by admiration and by fear, so that it has for us a value or necessity exceeding all other elements of life

put together, seems to coincide with the traditional and philosophical idea of a religion, no less than with the notions maintained, say, by David Hume, or by more modern writers on the natural history of religion. We may compare such expressions as these of Shakespeare:—

‘Keep your promise with no less religion.’

As You Like It.

‘When the devout religion of mine eye,’

Romeo and Juliet.

‘How many a holy and obsequious tear

Hath dear religious love stolen from mine eye.’

Sonnets, 31.

‘A coward, a most devout coward, religious in it’
(i. e. devoted, vowed, persistent in it).

Twelfth Night.

A man’s real religion, it may be said, is that set of objects, habits, and convictions, whatever it might prove to be, which he would die for rather than abandon, or at least would feel himself excommunicated from humanity if he did abandon. It would follow from this that his actual religion may differ in any degree from his nominal creed. On the other hand, it might be contended by students of the philosophy of religion that only those convictions which are called religious *par excellence* in the normal sense are capable of affording in the fullest degree that support, and that sense of triumphant unity, which seem to be the central facts of religious experience.

(2) The convictions which are called religious *par excellence* in the normal sense would commonly be admitted to be faith in God and in a future life, to which the Christian world would add, in one form or another, the doctrine of the Incarnation with the idea of triumph through sacrifice which attaches to it. The fundamental meaning of these forms of faith, that is to say, the answer which they give when we ask what truth they tell us about reality, is the central subject-matter of the philosophy of religion. Religious faith itself must of course be very clearly distinguished from the philosophical interpretation of it; although, on the other hand, there is no possible ground for denying religious value to the gnosis, or philosophical insight, in its genuine form as an endeavour to reinforce the unity of man as a perishing individual existence with something greater than himself. Faith in the ordinary sense is a kind of feeling. ‘The word for true religion in the Lutheran language is Glaube, and the essence of Glaube is fühlen. “Du musst bei dir selbst im Gewissen

fühlen Christum selbst, und unbeweglich empfinden dass es Gottes Wort sei”’ (Wallace, op. cit., 56). Because it is ‘immediate’ it is apt to be confused with credulity, and, when including in its object an accretion of historical matter, it may really assume an aspect of credulity. But what it means is neither credulity, nor yet a critical knowledge of fact or of truth. It means (Schelling, ‘Syst. d. gesammten Philos.’ 1804, *Werke*, Abth. i. Bd. vi. 558–9) ‘what is at once heroism, faith, fidelity to yourself and to God—a trust and confidence in the divine which excludes or abolishes all choice.’ It is essentially the conviction of a law in which the man is to live and act, and that this law is the best, or, strictly speaking, the only one possible for him. It would seem that human life can hardly be carried on without the presence of some such conviction, however fragmentary and however elementary. A certain courage and a certain guidance are needed for the mere conduct of existence from day to day; and the particular human being, if wholly deprived of the sense of unity with society and with the world, which is at the root of his reliance on his scheme of life, seems to perish like a plant deprived of warmth or nourishment.

The speculative interpretation and justification of religious faith is quite another matter than the apparently immediate feeling itself, and the question whether speculation does or does not constitute a form of religion seems to depend on the question whether it can be a mere piece of intellectualism, or whether it is a deeper experience, including the faith which it interprets.

The history of such speculation in the philosophy of religion centres round the ‘ontological proof of the existence of God.’ This argument is first explicitly known to history in the form given it by Anselm (1033–1109 A.D.), archbishop of Canterbury, who argued in substance that God as the greatest being conceivable must possess real existence; for if not, by conceiving of such a being as really existent we could conceive of something greater than him. It is an obvious answer that we cannot reason from essence to existence; we cannot infer that an object really exists, because real existence would enhance its perfection. This answer, made, as we are told, in Anselm’s time, and repeated in substance by Thomas Aquinas, is much the same as the criticism offered by Kant. The discussion, however, has been resumed by Hegel and later writers with the view of showing that the

verbal fallacy of the argument is no bar to its containing substantial truth. It is urged that the idea of God is not that of an object in the world of objects, but rather that of an organic or spiritual whole with reference to which alone both self and the world are knowable. It becomes, in fact, in accordance with the Kantian criticism, rather an idea through which we know, than an idea of an object of knowledge. And therefore it is urged that to reason from the idea of God to his reality is merely to recognize the movement by which the unity of things makes itself explicit alike in the experience which we call ourselves and in the experience which we call the world.

Speculation of this type implies the principle of 'immanence,' that is to say, of the divine being as present and revealed in the life of nature and of mind. The Christian doctrine of the Incarnation is interpreted in this sense, namely, that man, humanity, is an essential embodiment of the divine, so that if the humblest human being had not existed, God would be other than he is. The idea of love and self-sacrifice, of passing through the finite, or dying to live, is thus taken to be included in the essence of the divine nature. The conception of a future life is understood from this point of view to bear witness to the conviction that the human spirit is continuous with a unity which is not truly presented in the perishing series of time, but in some way realizes the conception of eternity, not as endless duration, but as a perfect experience.

The danger of this line of speculation, and a natural criticism of it, may be expressed by the term Pantheism. It would be urged, against the objection thus indicated, that the term Pantheism properly applies, or would apply, only to views in which the universe was regarded at once as equally divine throughout, and as truly and really consisting in the congeries of contradictory appearances—the aggregate of objects and subjects—which compose it as seen by the normal human being. But the edge of the criticism is turned if we understand that, as presented in our experience, the world consists of appearances of unequal value and possessing various degrees of reality; degrees, that is, of the character which any experience must possess that is to be regarded as finally stable and free from contradiction. For thus we are not obliged to identify the divine nature equally with the good and the bad, the great and the trivial, which present themselves in the world

as we know it. And this identification is the difficulty of Pantheism.

Recent speculation on the ultimate nature of the absolute reality has followed the general direction which has just been indicated. It is held that in a certain sense we are always experiencing reality, and that we can know at least in what direction to look for the better view of our experience which would remove its contradictions and permit it to be seen as part of an absolute whole.

(3) The different forms of creed and worship known to history are regarded from this point of view as stages and phases in the apprehension of the unity which includes both man's self and his world. Thus for the lower natural religions, it is held, the sense of social oneness and of alliance with the higher powers may find expression in the deification of some physical object; a relation of kinship between this object and its worshippers will then be the natural mode under which their common life will be realized. The fact that any such object must stand for more than it has power to express may help to account for the higher sense of a divine nature which sometimes comes to light among the very rudest populations, and which has recently been held to justify a revival of the theory of a degeneration from purer beliefs. The various phases of 'objective' religion, which represents in general the earlier stage of man's outlook upon the world, in contrast with the 'subjective' religions, such as Buddhism, Stoicism, and the later Judaism, when on the whole the mind has turned in upon itself and 'finds the voice of God mainly in the inner shrine of the heart' (E. Caird, *The Evolution of Religion*), are the content of such a philosophy of religion, in so far as it deals with the history of the imperfect religions.

(4) It follows from such a view that the distinction sometimes insisted on between ethical and non-ethical religions cannot really be maintained. From the first there is a tendency to rally some social group around the god, and to sanctify in his name some social ritual and observance; and wherever there are the beginnings of social unity and obligation there are also the beginnings of ethics.

Literature: the above account of the philosophy of religion follows chiefly the Gifford Lectures of WALLACE (Lects. and Essays on Nat. Theol. and Eth., 1898) and *The Evolution of Religion* (by EDWARD CAIRD, 1893),

together with a recent article, entitled 'Anselm's Argument for the Being of God—its History and what it proves,' by CAIRD in the *J. of Theol. Stud.* HEGEL's *Philos. of Religion* and *Lects. on the Proof of the Existence of God* (1832; Eng. trans., 1895) remain classical works on the subject; and especially the latter set of lectures, which he partly prepared for publication, represent in its earliest explicit form the view stated above as to Anselm's argument. SCHELLING's work above referred to (*Syst. d. gesammten Philos.*, 1804, *Werke*, Abth. I, vi. 546 ff.) contains a pregnant statement of his views. SCHLEIERMACHER's theological works and FEUERBACH's *Wesen des Christenthums* are highly valued. For HERBERT SPENCER's views see his *First Princ.*, and *Princ. of Sociol.*, iii. But it is a peculiarity of this study that, dealing with an experience which claims the highest reality, it cannot, so to speak, be properly pursued within its own limits. In HEGEL we must go to the *Logik*, as well as to the *Philos. of Religion*; in KANT to the three *Critiques*, as well as to the *Religion innerhalb d. Grenzen d. reinen Vernunft*. And this rule will lead us further. For the wellspring of genuine thought on religion we must go to PLATO (notably, for instance, to the account of the Form of the Good in the *Republic*), to SPINOZA, and in short to the great metaphysicians generally. Among recent works of this wider scope may be mentioned BRADLEY, *Appearance and Reality* (as also *Ethical Studies* by the same author); WARD, *Naturalism and Agnosticism*; and ROYCE, *The World and the Individual*; together with McTAGGART's criticisms and explanations of the Hegelian Logic (*Studies in the Hegelian Dialectic*, 1896, and more recent articles in *Mind*). For the science and history of religion, besides HUME's *Nat. Hist. of Religion* above referred to (a brief work dealing with generalities), one may avail himself of JEVONS, *Introd. to the Hist. of Religion*; LANG, *Making of Religion*; and ROBERTSON SMITH, *Religion of the Semites*, which latter seems to be recognized as a classical authority. From these, and from TIELE's art. *Religion* in the *Encyc. Brit.*, and FRAZER's *Golden Bough* (2nd ed.), a student may find his bearings in the immense literature of the subject. (B.B.)

Other notable books are PFLEIDERER, *Philos. of Religion* (Eng. trans.); MARTINEAU, *The Study of Religion*, and *The Seat of Authority in Religion*; LOTZE, *Microcosmus*

and *Philos. of Religion* (Eng. trans.). See also PAULSEN, *Introd. to Philos.* (Eng. trans.), and the titles cited under the other topics RELIGION. Down to date, but written from a theological point of view, is CALDECOTT, *Philos. of Religion in Eng. and Amer.* (1901). (J.M.B.)

Religion (psychology of). (1) The psychological dispositions and processes which are essential to religion.

(2) The theory of the psychological factors in religious doctrines and constitutions.

The psychology of religion has not had due attention. The views which make religion essentially non-natural have either, on the one hand, regarded man as naturally unreligious or irreligious, or, on the other hand, cut the psychological cloth to fit the theological pattern. Positive views on the subject may be put under certain headings.

(1) The RELIGIOUS INSTINCT (q.v.) view. This finds in the religious motive an innate impulse, predisposition, or propensity (any one of these terms is better than 'instinct'). This, like all theories which rest on native endowment, closes the door to analysis, and, moreover, finds justification for constructing the so-called 'instinct' in the ways which religious or theological systems respectively demand.

(2) The Intuition view and the Intellectualists. The view that the idea of God is an intuition is associated with the 'instinct' view in finding something native and irreducible upon which to rest the justification of positive religion; it differs, however, from it in allowing an indefinite development of argumentation in support of the intuition. In this characteristic the intuition view lays emphasis upon the theistic 'proofs,' and thus the religious state of mind becomes largely 'belief,' based upon argument, or 'faith,' based upon authority, in dogmatic formulations concerning, or direct revelations issuing from, the divine being. Natural religion, or theology, and Deistic teleology were developed either in company with or independently of certain sacred books. This view, in which intellectual factors predominated, characterized ecclesiastic, mediaeval, and pre-Kantian thought generally. The completed intuition position arose as a restatement of intellectualism in view of the destructive criticism of Kant—the intuition of God being Kant's idea of God, considered not as a formal principle of theoretical reason, but, like the intuitions generally, as an immediate deliver-

ance of consciousness having objective validity. The Scottish philosophers, who were in their way psychologists first of all, attempted to work out a psychology of the intuitions, and in so doing led up to a religious psychology, properly speaking.

(3) The Analytic and 'Critical' point of view. This consists in an analysis, or at least an attempt at direct examination, of the developed religious sentiment. It is this which yielded the best psychological results till the beginning of the later psychological movement called below 'genetic.' It is here that the classical views of Kant, Herder, Schleiermacher, and Matthew Arnold, &c., belong—views which were permanent contributions to the subject, because they rested upon actual psychological facts. Kant and Schleiermacher may be taken as representative of Rational and Emotional views respectively.

(a) With Kant the central fact of religion is the idea of God, which is a regulative principle of the practical reason. The religious and the moral life stand together upon this postulate. Religion is recognition of God and reverence for him. This places the emphasis on reason, but reason as regulative of the life of practice. And furthermore, reason (*Vernunft*) is not intelligence (*Verstand*); and Kant's view of religion is therefore rational, not intellectual. He refutes the intellectual view by his famous criticism of the arguments for the existence of God (see *THEISM*), and also by his failure to find that, even as a principle of pure or theoretical reason, the idea of God is ontologically valid. Furthermore, with Kant religion is not an independent problem, and much less is the psychology of it; it comes into the philosophical or epistemological problem, inasmuch as the idea of God claims for itself theoretical and practical universality, and so enters into the sphere of pure and, in a different way, of practical reason. Yet, as in all other problems into which both psychological and epistemological factors enter, Kant's work is of the first importance, both as leading to the intuition view in the way mentioned above, and also—and more especially—in making necessary a reconstruction in which psychological facts should lead the way. This had not been possible so long as dogmatic theology and the logical argumentation crystallized in the 'proofs' remained uncriticized.

(b) The school of Schleiermacher—the Emotionalists so called—went further than Kant

in denying to religion any sphere having separate intellectual content. The healing of the breach between *Verstand* and *Vernunft*, together with the reconciliation of pure and practical reason in the post-Kantian identity philosophy, left no dualism anywhere, no chasm on the right bank of which religion might perch and find its view directed backwards upon the secular, or experiential, fields of knowledge and faith. This made it necessary to find in religion some form of psychological reaction upon the one universal object—the absolute. This reaction is emotional, taking form in two phases of sentiment, which give character and furnish a criterion to religious experience. These are 'feeling of dependence' upon God, the object of worship, and 'feeling of mystery,' awe, or reverence towards him.

The work of this school has the advantage, from the psychological point of view, of pointing out definite psychological experiences as necessary to religion, a thing which the intellectualists found impossible. For the idea of God, whether content or intuition, is universal and, in so far, undefinable—especially as being universal in all experience. This led the way to the positive or scientific investigation which is now of the first importance, and which in its twofold form may be called 'genetic'; or, to say the least, it was in no way inconsistent with such investigation. Cf. *RELIGION* (evolution of).

(4) Genetic or Scientific. Research by the historical and evolution methods has taken on two great forms—anthropological and psychological, properly so named.

(a) The Anthropogenetic view: the treatment of religion as a great field of historical evolution. This is now yielding most important results. It is treated under *RELIGION* (evolution of); see also *RELIGION* (philosophy of), where certain of its results are pointed out. In addition, and as related to the psychological problem, we may note (1) that this study, by recognizing the essentially religious nature of primitive rites and cults, confirms the view that no one form of intellectual content—no one 'idea' as such—is necessary to religion. Rather what is common to low and high religions alike is certain active and emotional attitudes which ideas of various objects may call forth. Yet only such objects as *do* call these attitudes forth serve the religious motive, and this throws the actual criterion on the side of emotion and action. Here anthropology confirms the 'emotional' view (cf. *b*

below). (2) The objects of religious veneration, therefore, have a *symbolic* value. The gods are not experienced objects; they are objects fit for dependence, faith, reverence, and awe. This fitness or value is pitched higher as man develops and finds his experience reduced to objects obeying law. The God is ever the something behind the cloud, some one behind nature—the Great One who breaks law and works his will for his own, for ours, for a priest's, for a Redeemer's sake. And cults, religious institutions, ceremonials, sacrifices, &c., are attempts to cope with this unexperienced higher something; to bring into experience for satisfaction, help, salvation, that which cannot be found by sense or grasped in knowledge. (3) This, then, opens the question which psychology alone can answer: Why this constant drift, this groping beyond sense and thought, this demand—recurring in this form and that at every stage of more culture and of less culture—for a more-than-I, a being beyond, a God? This is the question of the impulse, propensity, spring of action which religion involves; and we come back to psychology and to the 'instinct' view in case no further analysis be possible. (4) In these investigations, moreover, the fact is constantly recognized that religion is a *social* phenomenon; no man is religious by himself, nor does he choose his god, nor devise his offering, nor enjoy his blessing alone. The whole is most intimately associated with social convention, custom, law—nay, often it is these things, and the whole of them. The priest is ruler, lawgiver, medicine man, no less than agent and embodiment of the divine efflatus. Religious sanctions often dictate social and ethical sanctions, and this dependence, at later stages of culture, is reversed. This is recognized as a safe result by the writers of both the articles RELIGION (philosophy of, q. v.) and THEISM (q. v.). (5) The object of religion is in *personal form*, whatever that may mean at the stage of evolution now reached, or then. This is one of the facts earliest observed, and perhaps the one most universally admitted by anthropologists. The theory of ANIMISM (q. v.), the GHOST THEORY (q. v.), that of ANCESTOR WORSHIP (q. v.), of religious PERSONIFICATION (q. v.), and of EJECTION (q. v.) all recognize and aim to formulate this class of phenomena.

(6) The Psychogenetic view. Here finally the appeal is made directly to psychological investigation; and having taken account of anthropological investigations as showing

actual religious products embodied in institutions, the psychologist comes to his investigation with the checks and control afforded by so much historical knowledge. This narrows his quest; for if religion is an active and emotional experience, a social experience, and an evolutionary or genetic experience, here are guiding threads of importance. Then, as to the object, it follows from the historical facts that the object of religion is a symbol, a meaning or INTENT (q. v.), not a content; it may preserve its meaning while changing its content. What genetic notion fulfils this condition? Again, how can this object be thrown into a series of *quasi-personal* forms, which always involve—create or result from—social relationships? This also restricts and aids the psychological determination.

The strictly psychological problem considered as meeting these requirements divides into two: we ask for an account (1) of the unity of religious experience, and (2) of the variety of religious experience. The question of unity is that of the one religious spring of action common to all religions and normal to normal individuals. The second question asks how this common impulse or motive takes the forms shown in different religions (comparative religion), in the genetic stages in the history of culture (evolution of religion), and in religious individuals (the psychology of prophets, religious seers, founders of sects, the inspired, the genius, &c.). The last named constitutes a variational psychology of religion, and can proceed only on the basis of the determination of the normal religious impulse, although by collecting data it may aid the former, as do variational statistics in other branches of inquiry. Very little has been done under this latter head (cf., however, James, *The Varieties of Religious Experience*, 1902, Gifford Lectures, published after this was written).

As to the unity of religious experience, the indications derived from anthropology may serve to guide. They make it necessary to say, first, that religious sentiment always involves three factors: (1) the recognition of other persons as standing in the same relation to the object of worship as myself, i. e. religion is a public thing involving duties and rights as between fellow men (the social factor); (2) the recognition of the religious object as also a person, of the same sort, though of higher character than my fellow man and myself (the personifying factor); (3) the reinterpretation of both the foregoing

factors with the genetic development of the thought of personality (the genetic personal factor).

These factors, taken separately, present problems having certain analogies in the psychology of the active life. The social factor is substantially the same problem as that of sympathy, notably as involved in the ethical: *how* do I recognize another as standing in the relation of duties and rights to myself, both being under a common law? Here the newer theory of 'ejection' is available; ego and alter are one thought through the reading into what is not-I of experience analogous to my own. The second or personifying factor also involves 'ejection'; yet here the reading-in is of the higher self—the law-abiding general or ethical self—which the private self-thought does not exhaust. God is a higher, a perfect self, having what the present writer has called 'projective' elements. The third problem is that of the genetic development of the personal self-thought to ever higher levels, from the organic to the impulsive, from impulse to intelligence, from intelligence to reflection; a development which carries with it the necessary reconstruction of the 'other' person, and also of the God-person, since it gives them its own character and content, by the fact of 'ejection'. This, then, makes religion a function of a personal development which is also social; and an adequate theory of the rise of personal self-consciousness accounts *ipso facto* also for the religious life. The impulse to read self into others, i.e. to recognize the experience of being a self as more than individual, is all that a genetic account of religion requires.

Religious sentiment, then, falls generically in the class called personal sentiments—emotional dispositions arising about the thought of personality, ethical sentiment being also in this class. It remains, then, to determine the specific character of this sentiment—the marks which distinguish it from others of the class.

Here the determinations of the analytic and 'emotional' schools are of extreme value. The 'feeling of dependence' and the feeling of 'awe or reverence' are alike the results of analysis and the direct inference from religious ceremonial and rite. The gods are propitiated to secure their favour and to mitigate or appease their wrath—both motives of dependence. They are served and worshipped with rites which are mystical, magical, and symbolic—evidence in turn to the essential feeling of

mystic awe with which they are approached. These two sentiments, therefore, stand out as by general agreement common and universal. They would seem, therefore, to give peculiar quality and coefficient to the religious state of mind; and they follow also from two other lines of inquiry, both of which yield psychological confirmation of the main result so far attained.

(a) The act of ejection whereby the self is read into another has a twofold significance: first, so far as it is of elements completely understood and experienced, the 'other'—in this case God—is known to be of such and such attributes and character. And these attributes, belonging to an infinite—or a very great—personality, may be gained for favour, or offended with loss. Just as we 'depend' on other persons who are situated to aid or damage us—the parent, the patron, the great friend—so, though to a fuller degree, we feel dependence on the Great Person of our faith.

But, second, ejection involves more. We find that our personal growth is one not merely of 'reading-in' into others, but of appropriation, of 'reading-in' into oneself. We constantly grow by imitative interpretation of the acts, habits, experience of others. There is thus a give-and-take—a 'dialectic'—of an ejective kind going on. Not only are there elements in the other person which we understand and intelligently anticipate with our feeling of dependence, but there grows up a habit of mind which hesitates before the unknown, the not-yet-learned elements of character of those from whom we learn. This we are not able to characterize in advance; it is mysterious, awesome. The sense of awe arises in the presence of the greater personality; here is therefore the origin of that aspect of religious emotion.

(b) The study of the actual rise of personal self-consciousness in the child adds—in the opinion of the writer—striking confirmation of these determinations. The genetic stages of the religious emotions are seen rising about the consciousness of self. And the consciousness of self grows up by the 'dialectic of personal growth' thus briefly indicated. Self is a social outcome, and with it religion, which is a function of this growth, is a social phenomenon as well (cf. the writer's *Social and Eth. Interpret.*, chaps. viii, x, which the section on the unity of religious experience mainly follows).

As to the varieties of religious experience, certain indications legitimately follow. The unity of religious experience is the unity of

normal self-consciousness; the varieties of religious experience indicate or flow from variations of self-consciousness. This point might be carried out in great detail. The alterations of self in the way of depression show themselves in all sorts of religious pessimism, melancholy, dejection, with corresponding sense of depression, conviction of sin, physical and moral laceration and asceticism. The exaltation of self, on the other hand, embodies itself in religious optimism, forms of personal alliance with God, inspiration, prophecy, visions, religious pride, and sinlessness. These, without exact description, are the opposed categories. Only the subtleties of change which personal self-consciousness undergoes in its variations or in normal temperamental varieties can serve as bases for tracing the actual varieties of religious experience. But the connection between the two is beyond dispute. Witness also the forms of so-called 'religious mania' and of other mental aberrations of which striking religious experience is a main symptom, and note the presence also of marked alteration of self-consciousness. It is a new religious personality which has the new revelation, inspiration, commission of vengeance, or other part to play, and it is in the structure of this consciousness of self that the reason of it is to be sought.

Literature: see the other topics RELIGION, also MAGIC, MYSTICISM, THEISM, SENTIMENT, and SANCTION. The social factor is emphasized by GUYAU, *Non-religion of the Future* (Eng. trans.); and ROYCE, *Studies of Good and Evil, and The World and the Individual*. Statistical studies are by COE, *The Spiritual Life* (1900); STARBUCK, *Studies in Religion* (based on slight and—*scribendo iudice*—defective 'syllabus' returns). Many anthropological treatises. See also under EJECT. (J.M.B., A.T.O., R.M.W.).

Religion of Humanity: Ger. *Menschenheitsreligion*; Fr. *religion de l'humanité*; Ital. *religione dell' umanità*. The religious system founded by Auguste Comte, in which the Supreme Being is Humanity, whose worship is to be maintained by a church organization, a priesthood, and an elaborate ritual.

The religion of humanity, which Huxley has characterized as 'Catholicism minus Christianity,' was a dream of Comte, which has never been fully realized. Outside of France it has had few adherents. In England the more intelligent advocates of POSITIVISM

(q. v.) practically eliminate from it the hierarchical elements as well as the elaborate ritual, and tend to reduce it more and more to a sort of propaganda of social ethics.

Literature: COMTE, *Works* (Eng. trans. by H. Martineau); CONGREVE, *Catechism of Positive Religion* (1858); BRIDGES, *A General view of Positivism* (1865); CAIRD, *The Social Philos. and Religion of Comte*; F. HARNACK, art. in *Nineteenth Cent.* (1884). (A.T.O.)

Religious Consciousness (in psychology): see RELIGION (psychology of).

Religious Consciousness (in theology): Ger. *religiöses Bewusstsein*; Fr. *conscience religieuse*; Ital. *coscienza religiosa*. That aspect of man's consciousness by virtue of which he is capable of religious ideas and motives, and of volitional and emotional response to them.

The religious consciousness is sometimes called, in view of its principal object, the God-consciousness. In germ at least it is a possession of all humanity; the religious consciousness is sometimes regarded as the source of all religious truth and the organ of a progressive revelation. In this sense it stands opposed to the claim of objective historic revelation. (A.T.O.)

Religious Instinct: Ger. *Religionsinstinkt*; Fr. *instinct religieux*; Ital. *istinto religioso*. A spontaneous tendency in man's nature to respond to religious objects and motives, the response arising from impulse rather than clear cognition. 'Religious impulse' is the more proper term.

The existence of an impulse that may be called religious is disputed by such writers as Benjamin Kidd, who regards religion as super-organic and imposed from without. On the other hand, such writers as Henry Rutgers Marshall and J. Mark Baldwin affirm a native religious disposition as inherent in man's nature. (A.T.O.)

This use of the term 'instinct' is not recommended; 'impulse' is the proper word. Cf. the definitions (1) and (2) of INSTINCT, of which (1) is preferred. The same is true of many so-called 'human instincts'; e.g. of 'humanity,' of 'imitation,' 'aesthetic,' &c.; they are native impulses or predispositions, not instincts. For further analysis of the religious impulse see RELIGION (psychology of); cf. also the other topics RELIGION.

(J.M.B., G.F.S.)
Literature: B. KIDD, *Social Evolution*; H. RUTGERS MARSHALL, *Instinct and Reason*; J. MARK BALDWIN, *Social and Eth. Interpret.*, chap. on 'Religious Sentiment.' (A.T.O.)

Remember [Lat. *re + meminī*, to be mindful, through Fr.]: Ger. *sich erinnern an*; Fr. *se rappeler, se souvenir de*; Ital. *ricordarsi*. To exercise MEMORY (q. v.). (J.M.B.)

Remembrance. A term used in a very loose way to cover MEMORY, RECOLLECTION, and RETENTION (see those terms, also for foreign equivalents), or the result of the memory function generally. (J.M.B.)

Reminiscence: Ger. (1) *Anamnese, Wiedererinnerung*; Fr. *rémiscence*; Ital. *reminiscenza*. (1) Translation of Greek ἀνάμνησις (Plato): recovery in human experience (memory) of knowledge, of which in a pre-existent state the soul had direct intuition; hence the origin or appearance of the universal rational principles contributed to experience by the mind. Really a theory of the *a priori*. See Plato, *Phaedrus*, 259 c; *Phaedo*, 72 c, 75 c; cf. Eisler, *Wörterb. d. philos. Begriffe*, 'Anamnese' (also for later writers). Cf. SOCRATIC PHILOSOPHY (d).

(2) Used loosely for memory which is somewhat vague and inexact. (J.M.B.)

Remission (of sins, in theology) [Lat. *remissio*, from *remittere*, to relax]: Ger. *Vergebung (der Sünden)*; Fr. *rémision (des péchés)*; Ital. *remissione (dei peccati)*. In the Christian scheme of redemption, that act of divine grace whereby the sinner is relieved from the penalty of his sin after its guilt has been removed by the atonement of Christ.

Pardon and remission are ordinarily used as equivalents; pardon, however, refers to the guilt of sin, while remission follows as a removal of the penalty. (A.T.O.)

Remonstrants [Lat. *remonstrare*, to protest]: Ger. *Remonstranten*; Fr. *Remonstrants*; Ital. *Rimonstranti*. The name given to the Arminians of Holland on account of their remonstrance against the sentence of the Synod of Dort condemning them as heretics.

Their adversaries, the adherents of Gomarus, replied with a counter remonstrance, and are called Contra-Remonstrants. (A.T.O.)

Remorse [Lat. *remorsus*, gnawed]: Ger. *Gewissensbiss*; Fr. *remords*; Ital. *rimorso*. Emotion of REGRET (q. v.) in which the grounds of sorrow include one's own ethical attitudes or acts; ethical regret.

The restriction to the ethical serves to give remorse a certain positive colouring, in which organic sensations, notably in the throat and digestive tracts, are prominent. There is also a certain setting of the muscles of throat and brow. The 'gnawing' of remorse, by which it occupies consciousness and torments,

seems to arise from these sensations. The unethical forms of regret, on the contrary, 'feel' more intellectual—in the head—and are decidedly more contemplative, less conative. Remorse as an ethical emotion involves—certainly in most cases—a social reference, and is, therefore, largely confined to positive acts of wrongdoing. We do not speak of remorse for omissions of duty and neglect of opportunity—unless they lead to positive ethical consequences—although we do feel regret in these cases. Akin to remorse is REPENTANCE (q. v.), with contrition. (J.M.B.)

Remote [Lat. *remotus*, from *re + movere*, to move]: Ger. *zurückliegend*; Fr. *éloigné*; Ital. *rimoto*. The older word for which mediate has of late been generally substituted. See IMMEDIATE AND MEDIATE. So in the phrases 'remote object,' 'remote mark,' 'remote scibile,' 'remote witness.' The opposite of remote is proximate. (C.S.P.)

Remote cause: that which produces an effect (remote) through or with the production of another effect (proximate). (J.M.B.)

In law, *remote cause* is an act of which the agent is not responsible for the remote effects.

Remote matter. (1) In Aristotelian metaphysics: matter relatively less prepared for the reception of a given form, by having received accidents or by substantial forms. (2) In logic: the matter of matter. Thus, terms are the remote matter of syllogisms, being the matter of propositions, which are the proximate matter. (3) In the doctrine of the matter of propositions which we find in the *Summulae*, remote matter consists of terms of a proposition which, from the nature of their significates, cannot either of them be true of the other. (C.S.P.)

Rémusat, Charles François Marie, Comte de. (1797–1875.) Born, and educated for the law, in Paris. When in his twenties he studied philosophy and the history of literature. In 1836 he entered the Department of the Interior, and in 1840, under Thiers, became Minister of the Interior. In 1842 he was made a member of the Academy of Moral and Political Sciences. Banished from Paris, he was recalled in 1872 by Thiers.

Renaissance [Fr., from Lat. *re + nasci*, to be born]: Ger. *Renaissance*; Fr. *renaissance*; Ital. *rinascimento*. The period of revival of learning, art, and culture in Europe in the fourteenth (Italy) and fifteenth centuries. Cf. HUMANISM, and REFORMATION. (J.M.B.)

Rent [OF. *rente*]: Ger. *Rente*; Fr. *rente*; Ital. *affitto*. (1) The price paid for the use

of real estate. (2) That part of the return on real estate which is due to the value of the land as distinct from the improvements. (3) Any excess of price over cost; particularly when such excess is due to the possession of a differential advantage. Cf. MONOPOLY.

Adam Smith used the word nearly in its first, or commercial, sense. Ricardo separated the return to capital from the return to land, and developed the second sense of the term (see DIMINISHING RETURN), which is known as economic or Ricardian rent. Mangoldt, Walker, Marshall, and others have shown that many other agents of production are remunerated under laws similar to those which Ricardo developed with regard to land. These returns are sometimes called *quasi-rents*; sometimes the term rent is so extended as to cover all these gains, as in definition (3). Even the differential advantages of consumers, so far as they are subject to similar laws, are brought under the name CONSUMER'S RENT (q. v.). (A.T.H.)

Repentance (in theology) [Lat. *repenitentia*, through Fr.]: Ger. *Reue*; Fr. *repentance*; Ital. *pentimento*. That change of mind in which a sinner, realizing the true nature of his sin, seeks divine forgiveness and purposes to live a new life.

Repentance is more than sorrow for sin or a sense of its guilt; it includes an active seeking for divine forgiveness, and a purpose to sin no more. According to the Roman Catholic doctrine, repentance must be accompanied by penance, inasmuch as the temporal effects of sin remain after its mortal guilt has been removed. Protestants repudiate this distinction, and hold that the divine grace freely remits all the effects of sin, both eternal and temporal, so far as these lie in the province of grace and not of nature.

Literature: see PENANCE. (A.T.O.)

Repose [Lat. *reponere*, to lay or place back]: Ger. *Ruhe*; Fr. *repos*; Ital. *riposo*. (1) Quiet, rest, calm; especially such composure of soul as excludes all agitation by passion or desire, and is suggestive of order, moderation, and often of dignity or latent power. (2) Art: such disposition of masses or pose of figure in stable equilibrium (in architecture or sculpture), or such shaping of features, or general simplicity, moderation, and harmony (in sculpture or painting) as to favour or express composure.

Repose was brought forward as an aesthetic category by Winckelmann (1765), who made it the distinctive characteristic of Greek art,

as the most important mark of 'beauty' as contrasted with 'expression.'

Literature: WINCKELMANN, *The Hist. of Ancient Art*; BROWN, *The Fine Arts*, 273. (J.H.T.)

Represent [Lat. *re + praesentare*, to present]: Ger. *repräsentieren*; Fr. *représenter*; Ital. *rappresentare*. To stand for, that is, to be in such a relation to another that for certain purposes it is treated by some mind as if it were that other.

Thus a spokesman, deputy, attorney, agent, vicar, diagram, symptom, counter, description, concept, premise, testimony, all represent something else, in their several ways, to minds who consider them in that way. See SIGN. When it is desired to distinguish between that which represents and the act or relation of representing, the former may be termed the 'representamen,' the latter the 'representation.' (C.S.P.)

Representamen: see REPRESENT.

Representation: Ger. (1) *Vorstellung*, *Idee*, (2) *Repräsentation*, (*reproducirte*) *Vorstellung*; Fr. *représentation*; Ital. *rappresentazione*. (1) A cognitive state considered as copying or in some sense representing its object.

(2) Recurrence of presentation.

(3) See REPRESENT; see also SIGN (in logic), and INDEX (in logic).

The first is the old usage. Hamilton (*Lects. on Met.*) classifies theories of knowledge as immediate and representative. The theory goes back to the Greek doctrine of εἰδωλα or images. Spencer (*Princ. of Psychol.*), who adopts this usage, uses re-representative for states which represent a representation—stand for something which stands for the object.

The second usage contrasts representation with presentation, as idea is contrasted with impression in the terminology of Hume (cf. Baldwin, *Elements of Psychol.*, 'Glossary'). This usage is current in the French (e.g. Rabier, *Leçons de Psychol.*). The contrast with presentation is difficult in view of the use of presentation as translation of the German *Vorstellung* (see PRESENTATION); and since we have the word idea in about the same sense, representation is not likely to be much used in the second sense. On the German use of *Repräsentation* see Erdmann, *Arch. f. syst. Philos.*, vii. (1891) 446. (J.M.B., G.F.S.)

Representationism: Ger. *Repräsentationismus*; Fr. *représentationisme*; Ital. *rappresentazionismo*. The doctrine that percepts stand for something behind them. See COSMOTHEIC IDEALISM, and IDEALISM.

In a certain sense it must be admitted, even by presentationists, that percepts only perform the function of conveying knowledge of something else. That is to say, they have to be combined and generalized to become useful knowledge; so that they may be said to represent their own generalizations. In this, representationists and presentationists may agree. But the dispute between them consists in this, that the representationist regards the percept in the light of testimony or a picture, from which by inference, or a mental act analogous to inference, the hidden cause of the percept may become known; while the presentationist holds that perception is a two-sided consciousness in which the percept appears as forcibly acting upon us, so that in perception the consciousness of an active object and of a subject acted on are as indivisible as, in making a muscular effort, the sense of exertion is one with and inseparable from the sense of resistance. The representationist would not allow that there is any bilateral consciousness even in the latter sense, regarding the bilaterality as a quasi-inference, or product of the mind's action; while the presentationist insists that there is nothing intellectual or intelligible in this duality. It is, he says, a hard fact experienced but never understood. A representationist will naturally regard the theory that everything in the outward world is atoms, their masses, motions, and energy, as a statement of the real fact which percepts represent. The presentationist, on the other hand, will more naturally regard it as a formula which is fitted to sum up and reconcile the percepts as the only ultimate facts. These are, however, merely different points of view in which neither ought to find anything absolutely contrary to his own doctrine. (C.S.P.)

Representative Government : see GOVERNMENT, and STATE.

Reprobation (in theology) [Lat. *reprobare*, to disapprove, condemn]: Ger. *Verdammung*, *Verwerfung*; Fr. *réprobation*; Ital. *riprovazione*. The passing over, in the divine decree of election, of a portion of the human race, so that they are left to perish in their sins.

In Roman Catholic theology the term is also applied to the eternal condemnation of the sinner who dies impenitent as distinguished from the condemnation of the penitent sinner to purgatorial fire.

Literature : see DECREES, PREDESTINATION, and PURGATORY. (A.T.O.)

Reproduction [for deriv. see PRODUCTION]: Ger. *Reproduktion*; Fr. *reproduction*; Ital. *riproduzione*. The recurrence of a content of consciousness considered as dependent on its previous occurrence. Cf. MEMORY, EVOCATION, RECOLLECTION, and REVIVAL.

Reproduction must be distinguished from repeated production. If I look at a tree, then look away, and then look at it again, the recurrence of the visual experience is not a reproduction; it is due to a repetition of the stimulus, and is to that extent independent of my having seen the tree before. But if after I have gone out of sight of the tree a mental image of it rises before consciousness, this is a reproduction; for the mental image owes its existence to the previous existence of the percept. It is obvious that the possibility of reproduction presupposes a persistent after-effect left by the original experience; such an after-effect is a trace or disposition.

Reproduction may be either free or determined by ASSOCIATION (q.v.). So far as it is free, it seems to be mainly determined by dispositional interest (see under INTEREST). The thoughts of the lover tend to fix on his mistress whenever he is not otherwise preoccupied. No associational cue seems necessary to set them in this direction. The same holds good of other absorbing interests. Any unsatisfied conative disposition tends to become conscious spontaneously, and the greater its intensity and complexity the stronger is the tendency. (G.F.S., J.M.B.)

Reproduction (experiments on, and method of): see MEMORY (experiments on).

Reproduction (in biology): see AGAMOGENESIS, FERTILIZATION, FERTILITY, and SEXUAL REPRODUCTION; and cf. HEREDITY, PHYSIOLOGICAL SELECTION, REPRODUCTIVE SELECTION, and STERILITY.

Reproductive (or Genetic) Selection : Ger. *genetische Selektion*; Fr. *sélection génétique*; Ital. *selezione genetica*. The theory according to which the most fertile individuals of one generation produce a large proportion of the next and, by the inheritance of fertility, also of subsequent generations, and so establish any characters which may be correlated with their relatively great fertility.

The theory was propounded and worked out by K. Pearson, and demonstrated for certain statistical data. Its importance as a factor in the theory of descent would seem to depend on the presence and variety of characters which are in uniform correlation with, or in some degree vary with, variations

in fertility. If largely effective it would in part work the preponderance or 'survival' of certain characters hitherto ascribed exclusively to the struggle for EXISTENCE (q. v.) with the elimination of the unfit. See FERTILITY (also for literature), and SELECTION (in biology). (J.M.B., E.B.P.)

Republic: see GOVERNMENT, STATE, and DEMOCRACY.

Repugnance [Lat. *re* + *pugnare*, to fight]: Ger. *Repugnantz*; Fr. *répugnance*, *incompatibilité*; Ital. *ripugnanza*. The relation between two propositions which can neither be true nor false together. (C.S.P.)

Repulsion: see ATTRACTION.

Res [Lat.]. THING (q. v.). In phrases: see IN ESSE, &c. (J.M.B.)

Res (in law) [Lat. *res*, thing]. (1) Property which is the subject of a claim.

An estate in settlement before a court of probate is viewed as property in its possession. 'That court has possession of the *res*, and the proceedings before it are in the nature of proceedings *in rem*' (Rockwell v. Bradshaw, 67 Conn. Law Reports, 18). *Res nullius*: property claimed by the possessor, of which there was before no owner, e.g. wild animals, derelicts, or goods intentionally abandoned.

(2) In expressions: a thing. *Res gestae*: things done, including words said, in connection with another act in such a way as to throw light upon its character, and therefore admissible in evidence for that purpose. *Res*

adiudicata: a matter settled by previous adjudication. *Res integra*: a point of law not previously settled by adjudication. *Res mancipi*: property transferable by *mancipium* under the old Roman law. *Res extra commercium*: things not the objects of private rights. By the Roman law these comprised *res divini iuris*, *res publicae*, and *res omnium communes*.

Right *in rem*: a general or absolute right to a thing availing against every one. Action *in rem*: an action to enforce such a right; also, in admiralty, an action against a thing, e.g. a ship, not naming any persons as defendants, to enforce a maritime lien. (S.E.B.)

Res de re praedicari non potest [Lat.]. Formula of NOMINALISM (q. v.), according to which universals have no independent reality. Cf. UNIVERSAL. (J.M.B.)

Resemblance [Lat. *re* + *similis*, like]: for foreign equivalents see LIKENESS OR RESEMBLANCE. The possession of an aspect or feature by two or more objects, in respect to which one of them might be taken for another, constitutes a resemblance, likeness, or similarity between or among these objects.

Objects are 'dissimilar' in respects in which DIFFERENCE (q. v.) characterizes them, and 'diverse' when these differences are qualitative. Various connections in which resemblance plays part in ancient and modern discussions are noted under LIKENESS OR RESEMBLANCE, IDENTITY (various topics), INDIVIDUAL, and RESEMBLANCE (consciousness of). Cf. also DIFFERENCE.

ILLUSTRATIONS.

A. *Animetic Resemblance.*

I. Coincident Resemblance: ANALOGY.

Psychological.

Like results from Darwin's 'analogous feeling stimuli.' Same movement, both reflex and voluntary.

Biological and Physiological.

ANALOGOUS ORGANS, HOMOPLASY, CONVERGENCE, Darwin's 'analogical' or 'adaptive' resemblance, syncretic resemblance, COINCIDENT VARIATIONS.

II. Recurrent Resemblance: Reduplication.

Recurrent psychic states from same nervous stimulation, 'alternating' psychoses, 'recurrent' insanity.

Reduplicated organs, results of REPRODUCTION, and HEREDITY.

B. *Mimetic Resemblance: MIMETISM.*

III. Serial Resemblance: 'Circular' functions.

Results of pathological mimetism, LALLING, CONTAGION (psychological and social), plastic imitation, psychological mimetism.

CIRCULAR REACTION, self-repeating functions, results of biological MIMICRY (q. v., 4).

IV. Imitative Resemblance: Conscious IMITATION.

Results of conscious and persistent imitation and volition, self and inner imitation, aesthetic SYMPATHY.

Results of self-imitative psychophysical functions.

Resemblance considered as a fact of observation enters into many current topics of science. There are certain general headings under which the various recognized forms of it may be classified. The accompanying table shows the results of such a classification, the principal headings of which are defined below, and in which the small capitals indicate topics treated separately *sub verbis*.

Amimetic resemblance. Resemblance between two objects (*a*, *a'*) produced quite independently of each other, either by (i) separate causes (*c*, *c'*, Fig. 1), or (ii) by the same cause (*c*, Fig. 2). These two cases (of which, as of those following, illustrations are given in the columns to the right in the table) may be called respectively 'coincident' and 'recurrent' resemblance.

Mimetic resemblance or mimetism. Resemblance in which one of the objects (that which is resembled) itself enters into the determination of the other (that which resembles the former) in the respect in which the resemblance holds good. Here, again, we have two cases, in one of which (iii) the copy, model, or object resembled (*a*) is itself the sole or efficient cause (*c'*) of the other object (*a'*)—its own cause (*c*) not acting (Fig. 3)—and in the other of which (iv) a second cause (*c'*) enters with the object *a* (considered as cause *c''*) into the production of *a'* (Fig. 4). These two sorts of resemblance we may call respectively 'serial' and 'imitative' resemblance—names, as before, which the study of the illustrations given in the table has suggested. (J.M.B., G.F.S., E.B.P.)

Resemblance (consciousness of): see LIKENESS OR RESEMBLANCE.

There has been much discussion on the distinction and interrelation of resemblance and identity. The main question at issue is whether all resemblance ought to be regarded as a partial IDENTITY (q. v.) (i. e. material as distinguished from individual identity). It has been recently maintained by certain writers, in particular by James and Stumpf, that this view is inapplicable to simple sensible qualities. When we say that purple resembles blue on the one hand and red on the other, according to them this cannot mean that purple is partially identical with blue and also partially identical with red; for purple is a simple quality, not a mixture. Logically, this position does not seem tenable. For how can the same quality have two distinct relations grounded on its own intrinsic nature if it contains no complexity? Practically, the question only becomes important

when assumed complexity or simplicity forms the starting-point for theoretical reasoning or practical adjustment. If the adherents of the simplicity view affirmed that a very blue purple cannot reproduce an idea by association which a pure blue could reproduce, they would be bringing the problem to a definite issue. If blue purple can function in mental process instead of blue, an element of blueness must belong to it, because this element is operative. (G.F.S.)

Resemblance (law of). A principle of the ASSOCIATION (q. v.) of ideas, according to which RESEMBLANCE (q. v.) between two mental objects of any kind is the reason of the recall of the one on the presence of the other.

This law, called also the 'law of similarity,' is commonly reduced to that of CONTIGUITY (q. v.)—a reduction dating back at least to Th. Brown—the elements, in each of the objects, which constitute them similar being identical and contiguous in each with the remainder of the object respectively. (J.M.B.)

Resentment: Ger. *Verdruss*, *Missbilligung*; Fr. *ressentiment*; Ital. *risentimento*. An emotion of displeasure arising from a sense of injury to oneself or another, and prompting to the resistance of such injury. Cf. ANGER, HATE, MALEVOLENCE, and REVENGE.

Butler uses the term to designate the principle in human nature 'which appears the direct contrary to benevolence.' As the latter principle is a desire for the good of others, the former is a desire for their hurt or evil. 'Resentment is of two kinds: hasty and sudden, or settled and deliberate. The former is called anger, and often passion; its evil consists in the unreasonableness of its occasion or the immoderateness of its degree or duration, not in its intrinsic nature. Deliberate resentment, on the other hand, 'seems in us plainly connected with a sense of virtue and vice, of moral good and evil.' Such resentment is not to be confused with malice. 'It is resentment against vice and wickedness: it is one of the common bonds by which society is held together; a fellow-feeling, which each individual has in behalf of the whole species, as well as of himself' (*Sermons*, viii. §§ 5, 8). (J.S.)

Reservation (mental): see EQUIVOCATION.

Residual: see ERRORS OF OBSERVATION.

Residues (method of) [Lat. *residere*, to remain]: Ger. *Restmethode*; Fr. *méthode des résidus*; Ital. *metodo dei residui*. A

method by which complicated phenomena are accounted for when one feature modifies another.

Thus, in the case of the motion of a planet, we first observe that it makes the circuit of the heavens from east to west once in twenty-four hours. But this is not exact; and if we note its place among the fixed stars at successive oppositions, we find that it moves, in a nearly uniform manner, from west to east. But this is not exact, for at one part of the heavens it always moves faster than at the opposite part, according to Kepler's laws. But this is not exact, for the part at which it moves fastest itself revolves very slowly, &c. Then going back to more obvious motions, when it is not in opposition it describes loops, of which one feature after another has to be taken account of. This is the general procedure of the method.

Literature: Sir J. F. W. HERSCHEL, *On the Study of Nat. Philos.*; JEVONS, *Princ. of Science*; MASCI, *Logica*, 417. (C.S.P.)

Residuum: see TRACE.

Resignation [Lat. *resignare*, to resign]: Ger. *Entsagung*; Fr. *résignation*; Ital. *rassegnazione*. (1) Emotional disposition of calm acceptance of the fortune, and of renunciation of craving and desire. Not an exact term. Cf. ASCETICISM.

(2) A term in the ethics of the 'Stoic School'; see SCHOOLS OF GREECE, and cf. APATHY. (J.M.B.)

Resistance [Lat. *resistere*, to withstand]: Ger. *Widerstand(-sfähigkeit)*; Fr. *résistance*; Ital. *resistenza*. That which withstands, opposes, or acts against a physical force.

Electrical resistance: property of a conductor which opposes the passage of an electric current. It is measured in ohms; the unit, or ohm, being the resistance offered by a column of pure mercury 104.81 cm. long, 1 mm. square, in section at 0°C.

Resistance coil: a coil of wire of known resistance.

Resistance box: a number of such coils arranged in a box; for use in regulating strength of electric potentials. (C.F.H.)

Resistance (sensation of): Ger. *Widerstandsempfindung* (or *-gefühl*); Fr. *sensation de résistance*; Ital. *sensazione di resistenza*. The sensation of opposition to muscular movement or obstruction of it. (J.M.B.)

The sensation of articular pressure is sometimes considered the 'sensation of resistance' (see SENSATION), which is reported by the

organs of touch and movement (skin, tendon, muscle, and joint). Among the sensations furnished by these latter, the sensation of TENDINOUS STRAIN (q. v.) perhaps ranks next in importance after the articular sensation.

Literature: KÜLPE, *Outlines of Psychol.*, 145; BASTIAN, *Brain as Organ of Mind*, 695. See also ARTICULAR SENSATION, MUSCULAR SENSATION, and EFFORT (bodily). (E.B.T.)

Resolution [Lat. *re + solvere*, to loose]: Ger. *Entscheidung* (Judd); Fr. *résolution*; Ital. *risoluzione*. The mental determination of a purpose; the act by which a PROJECT (q. v.) passes into a PURPOSE (q. v.).

Wundt makes the distinction between resolution and DECISION (q. v.) embodied in the definitions. (J.M.B.)

Respect [Lat. *respectare*, to look again]: Ger. *Achtung, Respekt*; Fr. *respect*; Ital. *rispetto*. Sentiment accompanying the recognition of what is excellent or even normally good in a person.

Respect is a term of less positive meaning than HONOUR (q. v., meaning 1). We retain respect for a person when he fulfils normal or average expectations; we honour him when he surpasses them. Yet respect attaches more intimately to personality: we may honour a man for his gifts, attainments, &c., after we lose respect for his character as a whole. Respect is essential to the higher sentiment, REVERENCE (q. v.). (J.M.B.)

Responsibility (consciousness of) [Lat. *respondere*, to respond]: Ger. *Verantwortlichkeit*; Fr. *responsabilité*; Ital. *responsabilità*. The consciousness of obligation attaching to the knowledge that one's acts of voluntary conation have been or may be effective in the determination or conditioning of subsequent events; for these events the actor calls himself, and others call him, in so far responsible.

This may be called psychic responsibility if we make a distinction between PSYCHIC AND PSYCHOLOGICAL (q. v.). Psychological or real responsibility, including moral and legal RESPONSIBILITY (q. v.), covers the case of effective determination of a stream of events by voluntary conation, whether the actor is conscious that this is the case or not. The difficulties gathering about the subject seem to be due (1) to the singular fact that the individual's psychic responsibility is often an *ex post facto* thing, attaching 'after the event' to many items which he did not consciously intend or foresee. The man who shoots his friend in mistake for a burglar, feels a certain responsibility for his friend's orphaned chil-

dren. The man who competes successfully feels a certain responsibility for his ruined commercial rival. This makes it impossible to measure even psychic responsibility in terms of end or intent. And (2) ethical and legal responsibility are still wider; they are not coterminous either with the responsible actor's end or with his consciousness of responsibility. It is, therefore, of the greatest importance that the distinction between psychic and psychological be here observed. (3) The matter is still further complicated by the psychological fact that psychic responsibility is not limited to the immediate nor yet to the remote consequences of volitional acts, but extends to all voluntary acts, whether positive or negative, and even to some which are only potentially or possibly volitional. In short, it is only those actions which are aconative (non-voluntary) or contra-conative (compelling) for which we feel no responsibility. This is reflected in the theory of INTENTION (q. v.) in law, and in the definitions of responsibility in criminal law—intention including permitted and omitted no less than committed acts, and being 'imputed' whether existing psychically or not. For the still further extension of the conception in law see RESPONSIBILITY (in law). Cf. also SANCTION (the various usages).

Literature: see the sections on Freedom and Responsibility in the textbooks of psychology and psychological medicine. (J.M.B.)

Responsibility (in law). The obligation to answer for an act done, to the extent of the sanction provided by law.

It does not necessarily presuppose any wrongdoing on the part of the person so held responsible. The law may make a railroad company responsible for fires set by its locomotives, though every care was taken to prevent the escape of sparks. A master may be held for an act of his servant done contrary to his orders. Responsibility for an act extends to all its natural and direct consequences. In criminal cases, responsibility is generally dependent on a wrongful intent, but such an intent is ordinarily inferred from the act. Insanity or mental incapacity may rebut or exclude such an inference. A statute may also impose a penalty, without regard to the defendant's intent, as by holding him criminally responsible for the act of his servant.

Literature: IHERING, *Zweck im Recht*, and *Geist des römischen Rechts auf den verschiedenen Stufen seiner Entwicklung*; SOHM, *Inst. of Roman Law*, chap. ii. (S.E.B.)

Responsibility (moral and social). Obligation attaching to acts of voluntary conation

to the extent to which they are considered as determining or conditioning ethical or social relationships.

This falls under psychological or real responsibility as contrasted with psychical (see RESPONSIBILITY, consciousness of). We say a man 'does not realize his responsibilities'; yet he is held to them, nevertheless. The term moral responsibility is often used to include both ethical and social situations, and is contrasted with RESPONSIBILITY in law (q. v.); as in cases of social ostracism or condemnation for actions not legally forbidden. (J.M.B.)

Responsibility is a favourite idea of the intuitionist school, who deduce from this essential property of a moral being the freedom of the human will. Mill and others, on the contrary, argue that responsibility means simply liability to punishment, and that, since the will is determined by the strongest motive, punishment is justifiable as an influence necessary to strengthen the weak will of the wrongdoer. Responsibility has often been interpreted theologically, though frequently also it has been understood as responsibility to one's own rational nature or conscience. Butler distinguishes the responsibility of man as a moral agent from the irresponsibility of things. 'A machine is inanimate and passive: but we are agents. Our constitution is put in our own power. We are charged with it; and therefore are accountable for any disorder or violation of it' (Preface to *Sermons*, § 13). (J.S.)

Rest: see MOTION AND REST.

Rest (organic) [AS. *ræst*]: Ger. *Rast*, *Ruhe*; Fr. *repos*; Ital. *riposo*. Cessation of active work to promote the building up in an organ or organism of compounds of higher potential energy and the elimination of waste 'fatigue' substances. Cf. ANABOLISM, and SLEEP. (C.F.H.)

Restraint (1) and (2) **Constraint** [Lat. *re* and *con* + *stringere*, to check]: Ger. (1) *Selbstbezwungung*, (2) *Zwang*; Fr. (1) *frein*, (2) *contrainte*; Ital. (1) *raffrenamento*, (2) *costrizione* (*morale*). The essential and common meaning of these terms is complete or partial arrest; yet what difference there is between them suggests a distinction between (1) self-arrest, as in the phrase 'self-restraint,' for which we never use the other term, and (2) arrest by some cause, reason, or principle foreign to the self, as in the phrases 'external constraint,' 'I am constrained to do this.' This distinction might well be made more general.

It would make all self-control, all ordering of the intellectual and moral life, restraint, not constraint, so far as we find it to be self-regulative.

Another distinction sometimes made, i.e. that restraint is negative or arresting and constraint positive or furthering, can hardly be maintained. Cf. CONSTRAINT (social), and SANCTION. (J.M.B.)

Restraint (ethical): see CONSCIENCE, IMPERATIVE (categorical), and SANCTION.

Result [Lat. *resultare*, to spring back]: Ger. *Ergebniss*, *Resultat*; Fr. *résultat*; Ital. *risultato*. Any determination considered as following upon the forces or conditions which enter into it. Cf. FORCE AND CONDITION.

Used principally for effect (see CAUSE AND EFFECT); but also for CONSEQUENCE, CONSEQUENT, logical CONCLUSION, ACTION (as following upon will), 'solution' in mathematics, &c. Cf. the topics in small capitals. (J.M.B.)

Resultant [Lat. *re + salire*, to jump, spring]: Ger. *Resultante*, *mittlere Kraft*, *Diagonalkraft*; Fr. *résultante*; Ital. *risultante*. The simplest force, or system of forces, which is the equivalent of several given forces.

If the forces act on a point, or pass through a common point, the resultant is a single force acting on that point with an intensity and direction determined by the law of COMPOSITION OF FORCES (q.v.). (S.N.)

Resultant Tone: Ger. *resultirender Ton*; Fr. *son résultant* (L.M.); Ital. *suono risultante*. (1) Tyndall's name for COMBINATION TONE (q.v., also for foreign equivalents).

(2) Melde's name for the intermediate tone that carries the BEATS (q.v.) when the pitch of the two primaries is separated by an interval less than the musical semitone. See *Pflüger's Arch.*, lx. (1895) 623. (E.B.T.)

Resurrection [Lat. *resurrectio*, from *resurgere*, to rise again]: Ger. *Auferstehung*; Fr. *résurrection*; Ital. *risurrezione*. The doctrine that the bodies of the dead shall be restored to life and reunited to their souls in such manner that continuous personal identity will be maintained.

The doctrine of the resurrection is not to be confounded with that of the immortality of the soul. A form of bodily renewal is involved in the transmigration doctrine of the Orientals and of Platonism. The resurrection is dimly foreshadowed also in the Old Testament. But it is raised to a dogma only in Christianity, where the resurrection of Christ is made a pledge of the resurrection of

the saints. The last judgment is to be preceded by a general resurrection.

Literature: ALGER, *Doctrine of Future Life*; BURNET, *State of the Dead* (London, 1835); ZEHRT, *Über die Auferstehung*; HODGSON, *Resurrection of Human Body* (1853).

(A.T.O.)

Retention [Lat. *re + tenere*, to hold]: Ger. *Aufbewahrung*; Fr. *conservation*, *réten-tion*; Ital. *ritenzione*, (*il*) *ritenere*. (1) The persistence of after-effects of mental process considered as conditioning or determining REPRODUCTION (q.v.). (G.F.S.—J.M.B.)

(2) The persistence of the mental DISPOSITION (q.v.). (G.F.S.)

(1) An after-effect of previous experience is necessary to reproduction—to the partial repetition of the original experience without repetition of the original conditions of its occurrence. This usage is recommended.

(G.F.S.—J.M.B.)

(2) If a process has continuity of interest, each phase of its development must be determined by the persistent after-effect of previous phases. When we hear one sound after another, and immediately judge that the second is louder than the first, it is by no means necessary that in framing the judgment the first sound should be present to consciousness as a mental image at the same time with the second. But the first must leave behind it some after-effect which so modifies the second as to determine the judgment. This may also be called retention. (G.F.S.)

Retentiveness. The power of RETENTION (q.v.). (J.M.B.)

Retina [Lat. *rete*, a net]: Ger. *Netzhaut*; Fr. *ré-tine*; Ital. *retina*. The innermost coat of the eyeball, consisting of a screen of nerve elements, some of them especially modified, upon which the image is normally focussed, and which act as the optical nervous mechanism for visual sensations. See EYE under VISION. (C.F.H.)

Retinal Light: see IDIO-RETINAL LIGHT.

Retinal Oscillation: Ger. *oscillirende Netzhauterregung*; Fr. *réaction oscillatoire de la ré-tine*; Ital. *reazione oscillatoria della retina*. See RECURRENT VISION.

Retinal Rivalry: Ger. *Wettstreit der Sehfelder*; Fr. *antagonisme* (or *lutte*) *des champs visuels*; Ital. *antagonismo* (or *contrasto*) *dei due campi visivi*. When the two retinas are stimulated simultaneously by strong lights of different colour (rivalry of colours), or are confronted with fields that cannot be given a unitary interpretation (rivalry of contours),

there results a peculiar instability of impression, an irregular alternation of colours or figures in the combined field, which is known as 'retinal rivalry.' Cf. COLOUR MIXTURE (binocular). The phenomenon has been explained in terms of attention (Helmholtz) and in purely physiological terms (Hering).

Literature: HELMHOLTZ, *Physiol. Optik* (2nd ed.), 916, 924; HERING, in *Hermann's Handb. d. Physiol.*, III. i. 380-5; *Beitr. z. Physiol.*, 308 ff.; H. PARINAUD, in *Ann. d'Ocul.*, cxix (1897). (E.B.T.)

Retribution [Lat. *retributio*, from *retribuere*, to repay]: Ger. *Vergeltung*; Fr. *rétribution*; Ital. *retribuzione*. The reward or punishment which awaits the soul in the future state of existence on account of the merit or demerit of the present life. In Christian theology, the future punishment of those who reject the offer of salvation and die impenitent.

The notion of retribution in the general sense is prominent in the religious thought of both East and West. The idea is usually associated with the process of transmigration through which the soul works out its destiny. The principle of retribution in Hindu thought is Karma, which is the very soul of transmigration itself. The Christian scheme is unfavourable to the notion of transmigration, and the tendency is to regard retribution in the light of finality. There are bodies of Christians, however, who hold to limited retribution and the final salvation of all men.

Literature: see KARMA, PUNISHMENT, TRANSMIGRATION, and UNIVERSALISM. (A.T.O.)

Retrospection and Retrospective Reference: see ORIGIN *versus* NATURE.

Return (economic) [Lat. *re + tornare*, to turn]: Ger. *Ertrag*; Fr. *produit*; Ital. *risultato, prodotto*. Price considered as a function of the form: cost \pm net profit.

Return would ordinarily be measured in the form of total price received, rather than of price per unit of product.

Any productive process begins with the consumption in one form or another of a certain amount of capital, and ends with the production of an uncertain amount of new wealth. From the private standpoint, the capital consumed or invested represents an expense, and the resulting wealth sold takes the form of a money return. From the public standpoint, the amount of capital consumed is properly measured as waste, and the wealth produced takes the form of a return in means of public enjoyment which may more than

replace the original amount wasted or sunk in the process. (A.T.H.)

Reuchlin, Johann. (1455-1522.) Educated in the chapel of the margrave of Baden, and at Paris and Orleans (law). Lectured on jurisprudence and belles-lettres at Tübingen, 1481, receiving the title of imperial councillor from the emperor; lived at the court of the elector palatine of Heidelberg, 1492-6; went to Rome, 1498, and became president of the Swabian confederate tribunal upon his return; professor at Ingolstadt, 1520.

Revelation (in theology) [Lat. *revelatio*, from *revelare*, to reveal]: Ger. *Offenbarung*; Fr. *révélation*; Ital. *rivelazione*. Any self-manifestation of the deity through natural or supernatural agencies. Especially: the communication of the divine thought or will through inspired human agencies; also the subject-matter thus communicated.

All religions presuppose some method of communicating the divine will to man. The term revelation acquires a specific import, however, in connection with the documents of religion. The sacred scriptures of any religion are the inspired basis of its doctrine and claims, and the question of the nature and import of revelation becomes one of great moment. In general it may be said that our estimate of revelation will depend upon our theory of inspiration.

Literature: see INSPIRATION; LÜCKE, *Versuch einer vollständigen Einleitung in die Offenbarung* (2nd ed., 1852); also the various New Testament Introductions. (A.T.O.)

Revenge [Lat. *re + vindicare*, to claim, through Fr.]: Ger. *Rache*; Fr. *vengeance*; Ital. *vendetta*. The emotion whose impulse prompts to return ill for ill: applied also to the ill which is returned.

Revenge has close affiliation with the other destructive emotions—anger, hate, malice. Its differentia seems to be the sense of owed and deserved ill to which the wrongdoer has made himself liable. It has a more organic instinctive form in the animals. In primitive societies it is not only measure for measure, but kind for kind—'an eye for an eye and a tooth for a tooth,' as well as 'a life for a life.' It is often made the germ from which social and statutory JUSTICE (q.v.) develops. The returning of good for good has no correspondingly urgent emotion, the feeling of gratitude being a tame and colourless affair compared with that of revenge. It illustrates—what is to be noted in other instances—that the unpleasant emotional states and

reactions are more developed, both as specific qualities and as having names, than the pleasant emotional states; e. g. there is no word for the opposite of jealousy, and no well-marked emotion of pleasure of such a type.

Literature: Revenge has had little special treatment; it is spoken of in passing in many of the treatises on EMOTION (q. v.). See also under JUSTICE. (J.M.B.)

Reverence [Lat. *revereri*, to be in awe, through Fr.]: Ger. *Achtung* (respect), *Ehrfurcht*; Fr. *respect* (respect), *révérence*; Ital. *riverenza*. (1) 'The feeling which accompanies the recognition of superiority or worth in others' (Sidgwick); disinterested RESPECT (q. v.) directed towards what is spiritually elevated and ideal.

Thee I revere for what thou art,
Nor fear for what thou hast,
Still undiscovered by me, in heart
And will. Reveal thy cast
Of soul more fully—still 'tis fast
I feel but reverence.

Thee I revere, unseen the fact
That moves thee for the day—
Unknown the motive to the act
That helps or hurts! But stay,
But go, our friendship by the way—
Still thee I reverence!

(J.M.B.)

(2) Kant so denominates the feeling which is aroused in a rational being by the contemplation of the moral law in its purity, or apart from inclination and self-interest.

As it is 'self-wrought by a rational concept,' this feeling is specifically different from all other feelings which arise from inclination and fear: it 'merely signifies the consciousness that my will is subordinate to a law.' 'Respect is properly the conception of a worth which thwarts my self-love.' See Kant, *Grundlegung z. Met. d. Sitten*, 22, note; Eng. trans. (Abbott), 17, note. Cf. RELIGION (psychology of). (J.S.)

Reversion (in biology) [Lat. *revertere*, to turn back]: Ger. *Rückschlag*, *Reversion*; Fr. *réversion*; Ital. *sopravvivenza*, *reversione*. ATAVISM (q. v.).

Literature: see ATAVISM. Important late titles are PEARSON, *Grammar of Science* (2nd ed.), and Proc. Roy. Soc. London, lxvi. (1900) 140. (J.M.B.)

Revery [Fr. *rêver*, to dream]: Ger. *Reverie*, *Träumerei*; Fr. *réverie*; Ital. *reverie*. Somewhat continued dwelling upon a train of recollections, usually from an emotional motive.

Revery differs from day-dreaming in that the latter constructs situations of an agreeable

and extravagant kind—'castles in Spain'—while revery selects trains of agreeable or emotionally toned recollections of real situations. (J.M.B.)

Revival (or **Recall**) (psychic or mental) [Lat. *re + vivere*, to live]: Ger. *Wiederaufleben* (in der Erinnerung); Fr. *réveil*, *rappel*; Ital. *reviviscenza*. The recurrence of a psychic state together with the identification of it as belonging to earlier experience.

The term includes the phenomena of MEMORY (q. v.), both voluntary (recollection) and spontaneous, and also those of EVOCATION (q. v.), i. e. the bringing up of images by suggestion; but it is narrower than mere REPRODUCTION (q. v.), since it involves the identification or RECOGNITION (q. v.) of the state revived. The noun recall is little used and is not needed; the use of recall as a verb is for a voluntary act of recollection.

This definition is made broad in order to allow for the differences of theory as to the nature of revival. The older and still very current theory holds that only images, cognitive states, are capable of revival, affective and conative experiences being revivable only as they are themselves first made objects of cognition. On this view only a certain kind of mental states, i. e. images, would fall under the definition. The opposed theory, of which that of 'affective memory' is the principal form, holds that this reduction of other states to cognitions is not necessary, since they can be directly revived as such. Upon this latter position depends the possibility of an 'emotional or affective logic,' which proceeds upon the abstraction and generalization of affective states together with certain aesthetic theories (cf. SENTIMENT, aesthetic). The definition leaves open this possibility.

Literature: that of MEMORY (q. v.) generally; see also the other topics referred to. On the revival of affective states see RIBOT, *L'Imagination créatrice* (with references to earlier papers by the same writer); PILLON, *Rev. Philos.*, Feb. 1901; MAUXION, *ibid.*, Feb. 1901; WITASEK, *Zeitsch. f. Psychol.*, xxv; URBAN, *Psychol. Rev.*, May, 1901, 262; July (especially), 1901, 360, 432 (critical articles with citations).

(J.M.B., G.F.S.)

Reward: Ger. *Belohnung*; Fr. *récompense*; Ital. *compenso*. See SANCTION, and cf. PUNISHMENT.

Reward (in theology) [OF. *rewarder*, an older form of *regarder*, to notice or heed]: Ger. *Vergeltung*; Fr. *rétribution*; Ital. *ricompensa*. The award of good or evil which the

soul receives after death on account of the deeds of the present life.

In the Hindu religion the reward is involved in Karma and the process of transmigration, and is evil rather than good. In Judaism and Mohammedanism the reward is good or evil as the divine grace may determine in view of the deeds of the present life. In Christianity the atonement of Christ makes it possible for every soul to escape Karma and attain the reward of good, evil being the lot of the finally impenitent only. (A.T.O.)

Rhetoric [Gr. *ῥητορικὴ*, from *ῥήτωρ*, public speaker]: Ger. *Rhetorik*, *Redekunst*; Fr. *rhétorique*; Ital. *rettorica*. The art of correct and effective discourse.

The Greeks, who more than any other people conceived of language as a plastic material of art, developed this art under an aesthetic instinct, though with a practical purpose. The purpose was to persuade, but to persuade through satisfaction of the sense for harmony in language as the direct exponent of life and personality. (B.I.W.)

Rhythm [Gr. *ῥυθμός*, measured motion]: Ger. *Rhythmus*; Fr. *rhythme*; Ital. *ritmo*. A repeating series of time intervals; events which occur in such a series are said to have rhythm. (J.M.B.)

Its stimulus is a succession of impressions (tactual and auditory are most favourable) which either vary regularly in objective intensity or are variously emphasized at recurrent intervals by the perceiving subject ('subjective accentuation'). The limits of the rhythmical 'unit' and the most favourable intervals between impression and impression (or maximal intensity and maximal intensity) have been made out. No general theory has as yet been proposed; but the available material has been collected in a monograph by E. Meumann, 'Untersuch. z. Psychol. u. Aesth. d. Rhythmus,' *Philos. Stud.*, x. 249 ff., 393 ff. (E.B.T.)

Literature: the citations above; see also the Psychol. Index, i. ff. 'Movement,' and the next topic.

Rhythm (aesthetic). (1) Primarily, the periodic recurrence of stress, emphasis, or accent in the movements of dancing, the sounds of music, and the language of poetry. Applied also, in music and poetry (both inclusive and exclusive of the previous usage), to the relations of time and quantity, represented by measure and metre. The term is loosely employed in connection with prose.

(2) Applied secondarily and somewhat meta-

phorically to the relatively regular recurrence of the same or similar features in architecture, drawing, and painting. In this sense closely related to SYMMETRY, and PROPORTION (q.v.).

Rhythm is historically one of the earliest factors employed in the production of aesthetic effects. It appears as fundamental in the primitive development of dancing, music, and poetry. The evolution of poetry and music into independent arts has been accompanied by a distinct decrease in the relative importance attaching to rhythm, as compared with the other elements from which these arts derive their aesthetic values. In aesthetic theory, rhythm has played an equally conspicuous part, and has, with its related categories, harmony, proportion, and symmetry, been universally recognized by aestheticians who deal at all with the formal elements of beauty. Its agreeable effect has been explained, in part at least, by reference (1) to its physiological basis (Marshall) as involving recurrent activities of organs refreshed by immediately preceding periods of repose (after the analogy of muscular fatigue and recuperation), organic activities under such conditions being highly efficient and pleasurable; also by reference to the heightened sense of expansion and life, which connects itself with the augmentation of muscular movements, induced by the more extensive nervous discharges following rhythmic stimulation (thus Gurney, who also recognizes the other physiological and psychological explanations here mentioned); (2) by reference to its psychological basis, as involving the arousal and subsequent satisfaction of expectation (Allen); and (3) by reference to its cosmological basis, as representing, like harmony, symmetry, and proportion, the definite order to which the cosmos is attuned, and in which, therefore, the organism, like all other cosmic elements, finds its own, and to which in consequence it most naturally and effectively responds (Aristotle).

Literature: KÖSTLIN, *Aesth.* (1869); GURNEY, *Power of Sound* (1880); WALLASCHKE, *Primitive Music* (1893); GROSSE, *Beginnings of Art* (1897). On wider sociological phases of rhythm and their connection with aesthetic processes see BÜCHER, *Arbeit und Rhythmus* (1896); SAURIAU, *L'Esthétique de Mouvement* (1889). (J.R.A.)

Richard of St. Victor. Died 1173. Educated by Hugo of St. Victor, and became an intimate friend of St. Bernard. Sub-prior of the convent of St. Victor, 1159; prior, 1162-73.

Right [AS. *riht*, Lat. *rectus*]: Ger. *Recht*; Fr. *droit*; Ital. *dritto*, *diritto* (a right). (1) A right action, intention, motive, or attitude is one which fulfils or conforms to DUTY (q. v.). (J.S.—J.M.B.)

The intuitionists have regarded the 'right' as an ultimate ethical category, while the hedonists have explained it as simply the means to the 'good.' The Greek moralists generally followed the latter course, if they did not substitute the notion of 'good' for that of 'right.'

(2) A 'right' is the correlate of a duty; e.g. it is the duty of a child to obey his parents, and his parents have a right to his obedience. Besides moral and 'natural' rights, there are legal rights; and the relation of the latter to the former has been a subject of much controversy in both moral and political science. Cf. RIGHT (in law), STATE (philosophy of), and NATURAL RIGHTS.

(3) The term is used in German to denote the general system of rights and obligations, especially as capable of being enforced by law. Right in this juridical sense is called by Hegel 'abstract right,' and is for him the first and most external stage of the ethical process which, as a whole, is the subject-matter of Rechtsphilosophie. Cf. STATE (philosophy of).

Rightness is the quality by virtue of which anything is right (in any of the senses given). For the distinction between material and FORMAL RIGHTNESS, see the latter topic.

Literature: works on ethics; RITCHIE, Natural Rights. See also the topics mentioned. (J.S.)

Right (in law). (1) A legal power of one person over another; 'a capacity residing in one man of controlling, with the assent and assistance of the state, the actions of others' (Holland, *Jurisprudence*, chap. vii. 71).

(2) The aggregate of the principles by which rights (sense 1) are determined; the science of rights (Smith, *Right and Law*, §§ 228, 244).

No right can exist in one person without a correlative duty on the part of another or others. *Relative rights* are those involving duties of particular persons; *absolute rights*, those involving duties on the part of all other persons, as the right to life, liberty, and property. My right to my house in my possession is a *real right*: it attaches to the thing (*res*) against all the world. If I am wrongfully dispossessed, I have a *personal right* to recover possession from the wrongdoer in a real action. *Vested rights*: those already existing

in a certain person, as owner, whether absolute or defeasible.

Ius, Recht, droit, diritto may signify either right or a right. 'To express the distinction between "law" and "a right," the Germans are therefore obliged to resort to such phrases as "objectives" and "subjectives Recht"; meaning by the former, law in the abstract, and by the latter, a concrete right' (Holland, *Jurisprudence*, chap. vii. 72).

'Right,' or abstract law, in the views of the historical school of jurisprudence, as expounded by Savigny, is no absolute, universal, and immutable rule, but one of the forces of society with which it changes, in accordance with fixed laws of development. Cf. STATE (philosophy of).

Literature: for an exposition of the moral theory of legal rights, see SMITH, Crit. Hist. of Mod. Eng. Jurisprudence, chap. viii; and for an elaborate discussion of civil rights, WOOLSEY, Polit. Sci., i. Pt. I; BOSANQUET, Philos. Theory of the State; RATTO, Sociologia e Filosofia del Diritto, chap. v ff. (1894); FILOMUSI-GUELFI, Del Concetto del Diritto, &c. (1874); MIRAGLIO, Filosofia del Diritto. (S.E.B.)

Right and Wrong Cases (method of): see PSYCHOPHYSICAL METHODS.

Righteousness [Gr. *δικαιοσύνη*]: Ger. *Rechtlichkeit*, *Gerechtigkeit*; Fr. *justice*; Ital. *giustizia*. (1) Disposition to observe law and to aid its enforcement.

Righteousness becomes legalism when it attaches importance to the letter and form of law as positively enacted. Cf. JUSTICE. (J.M.B.)

(2) Plato's term for the most fundamental of the four cardinal virtues, the presupposition of all the others. It is sometimes translated 'justice.' He defines it as the doing of its own proper work by each part of the soul, and by each class in the state. The state is righteous when the legislators legislate wisely, when the auxiliaries enforce this legislation, and when the subject class obeys; the soul is righteous when reason plans its good, when 'spirit' (*θυμός*) keeps the appetitive element (*τὸ ἐπιθυμητικόν*) in subjection to reason's law, and when appetite obeys (*Republic*, iv. 433-43). Aristotle distinguishes two main senses of the term, a wider and a narrower: (1) obedience to law, synonymous with complete virtue; (2) fairness or equality (*Eth. Nic.*, v. 1). (J.S.)

Righteousness (in theology) [AS. *rihtwises*, 'righteousness']: Ger. *Gerech-*

tigkeits; Fr. *justice*; Ital. *giustificazione*. (1) The righteousness of Christ, the merit purchased by Christ's obedience which may be imputed to the sinner as the ground of his justification. (2) Righteousness of the creature, the state of conformity to the divine law and of acceptance with God: more specially, the state of the sinner to whom the merit of Christ's obedience has been imputed and appropriated through repentance and faith.

Literature: A. RITSCHL, *Die christliche Lehre v. Rechtfertigung*, &c. (1870-4; Eng. trans. of vol. i, Edinburgh, 1872); theologies of HODGE, SHEDD, VAN OSTERZEE, DORNER. (A.T.O.)

Right-handedness: Ger. *Rechtshändigkeit*; Fr. *dextralité*; Ital. *destrismo*: see DEXTRALITY.

Rightness: see RIGHT (ad fin.).

Right Reason: trans. of the Gr. *ὁρθὸς λόγος* (Lat. *recta ratio*). Used by Aristotle (*Eth. Nic.*, vi. 13, 1144 b 23) for moral or PRACTICAL REASON (q. v.). For other usages see Eisler, *Wörterb. d. philos. Begriffe*, 'Orthos Logos.' Cf. Logos under REASON. (J.M.B.)

Rights (philosophy of): see STATE (philosophy of).

Rigorists (-ism): Ger. *Rigoristen (-ismus)*; Fr. *rigoristes (-isme)*; Ital. *rigoristi (-ismo)*. Rigorism is a term used by Kant in a special sense—and sometimes used by later writers in a wider sense—to signify an ascetic or anti-hedonistic point of view in ethics.

In the wider sense, Kant himself would be included, with the Stoics, in the school of rigorists.

'It is in general important for ethics,' says Kant, 'to admit, as far as possible, no intermediates, either in actions (*adiaphora*) or in human characters. . . . Those who are attached to this strict view are commonly called rigorists (a name that is meant as a reproach, but which is really praise); and their antipodes may be called latitudinarians. The latter are either latitudinarians of neutrality, who may be called indifferentists, or of compromise, who may be called syncretists' (*Die Religion innerhalb d. Grenzen d. blossen Vernunft*, 23, 24; Eng. trans. (Abbott), 329). (J.S.)

Rigour [Lat. *rigor*, stiffness]: Ger. *Starrheit*, *Totenstarre* (rigor mortis); Fr. *rigidité*; Ital. *rigidità*. A stiffening of the tissues (generally applied to muscles) due to coagulation of their fluid or semi-fluid protoplasm, which occurs after death (*rigor mortis*, or

cadaveric rigidity) or upon heating (*rigor caloris*, or heat stiffening).

Rigormortis occurs in warm-blooded animals and in man in from ten minutes to seven hours after death, and may last from one to six days. Heat is given off in the process; and since different muscles contract at somewhat different periods, movements may occur which give rise to the notion that the body may have moved, or is still alive. Under exhausting disease, especially of the brain and spinal cord, in conditions of extreme fatigue, rigor mortis may occur so quickly as to catch the body in its last living attitude. This is known as 'cataleptic rigour.' (C.F.H.)

Ritschl, Albrecht. (1822-89.) Studied at Bonn and at Halle. Became Privatdocent, and later professor of the theology, at Bonn, 1846-64; at Göttingen, 1864-89. He adhered to the Tübingen school until 1857, when he left it. Cf. RITSCHLIANISM.

Ritschlianism: Ger. *Lehre von Ritschl*; Fr. *doctrine de Ritschl*, *Ritschlianisme*; Ital. *dottrina di Ritschl*. The principles of the school of Ritschl, which represents, negatively, opposition to dogmatism and rationalism in religion, while positively it builds on the personal experience and person of the historic Christ as the subjective and objective sources of religious truth.

The Ritschlians seek to divorce theology from speculation by denying the validity of all judgments in the religious sphere except judgments of value. They also reject dogmatic Christianity with its presupposition of the supernatural, and seek in the person of Christ as an historic phenomenon the source of objective revelatory truth. The words and deeds of Christ and dogmatic statements about them are of secondary importance. The person of Christ as a persistent objective fact, in articulate union with the subjective religious consciousness, is the fountain of all religious truth and knowledge.

Literature: RITSCHL, *Rechtfertigung*, u. *Versöhnung* (3rd ed., 1888), and *Theol. u. Met.* (2nd ed., 1887); HERMANN, *The Communion of the Christian with God*; STÄHLIN, Kant, Lotze u. Ritschl. (A.T.O.)

Ritter, Heinrich. (1791-1869.) Educated in theology and philosophy at Halle, Göttingen, and Berlin. Professor of philosophy at Berlin, 1824; at Kiel, 1833; and in Göttingen, 1837-69. His *History of Philosophy*, in twelve volumes, is his greatest work.

Ritual [Lat. *ritualis*, from *ritus*, a rite]:

Ger. *Ritual*; Fr. *rituel*; Ital. *rituale*. A body of prescribed forms for conducting religious rites, ceremonies, and worship.

In the broad sense ritual includes any prescribed form, whether the words be dictated or not. Strictly, ritual and liturgy are employed as equivalent terms. The Protestant churches have tended as a rule to simplicity of ritual in contrast to the elaborate forms of the Roman Catholic communion. There sprang up towards the end of the 19th century, however, an important movement in the Anglican communion in the direction of a more elaborate ritual.

Literature: see TRACTARIANISM. (A.T.O.)

Rivalry [Lat. *rivalis*, pertaining to a river]: Ger. *Wettstreit*; Fr. *rivalité*; Ital. *rivalità*. Of the three forms of rivalry distinguished below, COMPETITION (q.v.) and struggle for EXISTENCE (q.v.) are defined under those topics. The third, personal rivalry, is the relation between two persons, or more, which arises from their mutual intention or effort to excel each other in attaining an end which they have in common.

There are three great cases of rivalry which it is essential to distinguish, especially in view of current confusions arising from lack of discrimination: (1) biological rivalry, or struggle for existence; (2) personal or conscious rivalry or emulation, to which the term rivalry is more generally restricted; and (3) commercial and industrial rivalry, or competition.

(1) The forms of struggle for existence are pointed out under that term: the essentials of biological rivalry are survival, with subsequent production of offspring by and with physical heredity. No use of this form of rivalry by analogy to or from other forms is legitimate which does not recognize this fact of physical reproduction. Without this there is no *effective* biological rivalry.

(2) In personal rivalry we have all forms of individual competition for personal pleasure, profit, gain, victory, &c. It is, so far as the actual contest goes, the same as the second form of struggle for EXISTENCE (q.v., 2); but it is narrower, since it includes only those cases in which the individuals are directly and consciously exerting themselves against each other. It is a psychological fact, never a purely biological one. Cf. EMULATION.

The psychological factors involved include: (a) the particular impulse appealed to in exciting the effort: whether 'desire of being a cause' (Groos), called in the older English

literature 'love of power'; desire to gain advantage—pleasure, reward, gratified pride, &c.—the older 'love of gain'; intellectual exercise—PLAY (q.v.) of the faculties; or other. All of these enter in cases of personal rivalry; and in adult life probably also in many instances reflective motives, such as pure love of success, love of the game as such, and malice towards and jealousy of competitors. (b) The psychological requisites of the *personal-rivalry-situation* as a whole. These are those of the social bond, in which the self and the other (ego and alter) are held in a common network of social relationships within which the contest takes place, and by which its rules and conditions are prescribed. This, it is well to note, involves as much co-operation as competition. The rivalry is never entirely rivalry, and it could not be rivalry at all but for the great mass of co-operative thinking, feeling, and action which precedes and conditions it. In short, personal rivalry is an essentially co-operative thing: it is a social situation in which, it is true, the pole of self-emphasis, assertion, and even aggression is very prominent, but in which, nevertheless, it is only one pole of the play of elements which constitute the thought of self as a 'socius' or personal companion to others.

It is, therefore, sharply distinguished from biological struggle for existence. The latter is operative under the law of physical reproduction, guided by natural selection with reference to utility in a biological environment. This, on the contrary, is operative in a social environment where social tradition through imitation and invention are the conserving and ordering factors, where the environment is psychological and moral, and where the criterion of utility yields to that of individual choice, selection, reflection, and, it may be, caprice.

This is not to say, however, that personal rivalry may not be involved in biological survival. It is evident that the capacity for personal psychologically motivated struggle may be of critical utility to a species, and so its possessors may be 'naturally' selected. But true as that is, it still remains a case of biological rivalry, and is subject to its laws. The purely social rivalry, as such, remains a different phenomenon, and cannot be subsumed under the biological.

(3) Industrial and commercial COMPETITION is treated under that topic. Its relation to the two preceding forms of rivalry may, however, be briefly indicated.

Two typical forms of it should be distinguished: (a) competition of individuals, which we may call 'free' competition; and (2) competition of agencies either individuals or organizations, which we may call 'restricted' competition. This distinction is essential, for it indicates two types of competitive activity analogous respectively to 'personal' and 'biological' rivalry.

(a) Free competition, considered as a type operative in industrial and commercial affairs, leaves to the individual freedom of enterprise, initiative, and method of operation in his attempt to succeed. It is, therefore, psychologically motivated, and rests directly upon the individual's capacity, temperament, and social feeling. The economic motive is tempered and modified by the individual's character, and varies all the way from pure egoism or love of gain to the most humane and social concern for others' welfare and success. It appears, therefore, that in free competition we have in operation the factors involved in personal rivalry, but directed to an economic end. This end or view gives to the agencies of production, trade, &c., a certain real disinterestedness which appears inhuman, and is often made the excuse for what is really so; but yet industrial organization in which free competition is the dominant form is a mode of social organization in which the factors involved are those essential to the maintenance of social life, and consistent with its other and more altruistic modes. Hence the growth, within the ordinary machinery of industrial economics, of various purely social and ethical features: humane labour laws, hygienic surroundings, libraries and reading-rooms, baths, lecture courses, lyceums, &c., not only permitted but provided by employers, together with such more intrinsic arrangements as profit-sharing, increasing wage, pensions, labour insurance, &c. In essentials, therefore, this form of competition *is* (not merely represents) personal rivalry inside the industrial world. It is not, *nor is it analogous to*, biological struggle for existence.

In another point commercial competition involves psychological factors; appeal is made to the desire and choice of the consumer—what is known as demand. This demand may be reached either by direct rivalry for the consumer's patronage, or indirectly through means which increase the use of certain articles, set the style, limit variety, &c. In these ways of directing,

stimulating, and controlling demand, all the competitors may be alike benefited by the success of one. This is different from the use of brute force, and also from the division of a fixed amount of patronage or gain: these latter bring the usual methods of biological rivalry. Cf. SOCIAL ORGANIZATION.

(b) The second form of economic rivalry—'restricted' competition—is a different matter. It arises when individuals band together, either voluntarily or under social compulsion or persuasion, to pursue common economic ends in association. This gives to the group economic standing as an *agency*; and the members cease to act as individuals. The result is the formulation of purely economic rules of procedure—of defence and offence—and the elimination of individual temper, judgment, and sense of personal and social responsibility.

The direct result is that such a society becomes a *group*, and when engaged in competition with other groups, gives the phenomenon of GROUP SELECTION (q. v.); yet it is group selection, in the strict biological sense, only in part. As to the struggle, strictly speaking, of group with group, it is struggle for existence in so far as it means elimination of some groups and survival of others. But its results are socially conserved and handed down, not passed on by physical reproduction and heredity. So the resemblance is still partly analogy. Even restricted competition is not a biological fact. Even its most iron-clad and 'inhuman' forms are intelligent; intelligence unmoved by feeling is its watchword. And its forms of rivalry are very largely those of one master intelligence pitted against another.

Yet in this phenomenon of restricted competition we have the nearest social approach to biological rivalry as such, and that in certain unaesthetic features in which economic utility is the controlling end, if not the only one. First among these is the opportunity it affords of subordinating and destroying normal personal competition with its natural control by social and moral sentiment. Second, follows, to take the place of these controls, the need of state control: there would seem to be no other alternative. Third, we find not only group competing with group, but class organizations arrayed against each other, when the closest co-operation is essential even for the purest economical utilities; as of labour organizations against capital, employed against employer. And fourth, all are contributory to the great damage done to society by the

interference with personal liberty of contract and choice of work under the oppressive sanctions of the organization, which claim to regulate economic conditions. In all these respects the industrial environment in which modern corporate agencies operate is analogous to the biological: for utility is the criterion of survival, and economic utility is in many respects analogous to biological. See UTILITY.

The contrasts presented by these three sorts of rivalry are sharply brought out when we ask what forms of co-operation of individuals they severally involve. So far as co-operation enters into biological struggle for existence, it is instinctive and unreflective: as the gregarious and mass actions of herds or other companies of animals. It is a phenomenon of a biological sort produced by the operation of natural selection. Intelligent co-operation, to be available in the struggle, must be not for its direct results, but as representing a type of individual which it is of utility to preserve by the laws of heredity.

In personal rivalry, and with it free economic competition, we have the intelligent and reflective co-operation which illustrates the presence of a social and moral self in some degree of development.

In 'restricted' competition we revert to the formula which makes economic utility paramount, and only that form of co-operation possible which subserves it. This may arise among individuals within the group so far as it renders the group as such more efficient as against others, and also as between different groups or agencies for the ends of common utility.

Literature: see EXISTENCE (struggle for), and COMPETITION (especially title by EFFERZ); also ELY, Competition, Pres. Addr. Amer. Econ. Assoc., December, 1900. Cf. SOCIAL ORGANIZATION. (J.M.B., F.H.G., A.T.H.)

Rochow, Friedrich Eberhard von. (1734-1805.) Feudal superior of Rekahn, patron of the bishopric of Halberstadt.

Roman Law: Ger. *römisches Recht*; Fr. *droit romain*; Ital. *diritto romano*. (1) The law of Rome as it existed from time to time, throughout its history, until the fall of the Eastern empire.

(2) The law of Rome as codified under Justinian. See CODE.

The gradual growth and development of Roman law is sketched in the *Digest*, i. 2, *de origine iuris*, &c. It found its first definite written expression in the Twelve Tables ('XII'), promulgated in the 5th century

B.C. Upon these a system of jurisprudence was built up, mainly by the efforts of private juriconsults, whose opinions and treatises were from time to time adopted as rules of decision by the praetors in their annual edicts. This praetorian law was in the early empire put into the form of a perpetual edict. It was the principal part of the *ius honorarium*, which applied the principles of equity and natural justice in softening the rigour and formality of the earlier law (*ius civile*). It was largely in the form of a law regulating civil actions, the nature of the remedy really defining or creating the legal right. Then came the Theodosian Code (5th century of our era), and the *Corpus Iuris Civilis* of Justinian in the following century, the latter putting Roman law into a shape convenient both for students and practitioners. After the division of the empire, the Roman law long remained in the West the personal law for the Romans, even when the barbarians held rule. In the East (where Justinian reigned) it became overlaid by new imperial constitutions, and obscured by Greek commentaries, but was partly restored by an official code known as the *Basilica*, promulgated in A.D. 887. No trace of it remains in Turkey, but the *Basilica* have had great influence in shaping the legal conceptions of modern Greece. Roman law is the foundation of the jurisprudence of Central and Southern Europe, England and Ireland excepted.

Literature: SAVIGNY, *Gesch. d. römischen Rechts im Mittelalter*, and Syst. d. heutigen römischen Rechts; GIBBON, *Decline and Fall of the Roman Empire*, chap. xlv; HUGO, *Hist. de Droit romain*; IHERING, *Geist d. römischen Rechts*; CUQ, *Inst. juridiques des Romains*; SOHM, *Inst. of Roman Law*. (S.E.B.)

Romanes, George John. (1848-94.) Educated at Cambridge, England; fellow of the Royal Society, 1879; became an intimate friend of Charles Darwin; Fullerian professor of physiology, Royal Institute of London; Rosebery lecturer on natural history in the University of Edinburgh. He founded the Romanes Lecture at Oxford. He wrote chiefly in general biology and genetic psychology.

Romanism and Roman Catholic Church: Ger. *Dogmen der katholischen Kirche*; Fr. *Romanisme, Eglise catholique romaine*; Ital. *religione cattolica apostolica romana*. The system of doctrines and polity of the Roman Catholic Church. The Roman Catholic Church is that ecclesiastical body

which has its historic centre in Rome and its supreme power vested in a Sovereign Pontiff, who claims to derive his authority directly from St. Peter; as such it is called 'the Papacy.'

The most distinctive features are the papacy proper and the degree to which the individual is subordinated to the organic will of the Church in matters of belief and judgment. Reformed Christianity rejects the Roman hierarchy and recognizes a larger sphere of freedom for individual belief and judgment. See Roman Catholic Church Philosophy, under St. THOMAS (philosophy of).

Literature: C. F. B. ALLNUTT, *Cathedra Petri* (2nd ed., 1878); A. HARNACK, *Dogmengeschichte* (2nd ed., 1888); RUDOLPH SOHM, *Kirchenrecht* (Leipzig, 1892), i. (A.T.O.)

Romantic [Fr. *romantique*, from *romant*, a romance, so named because early romances were written in the Romance dialect]: Ger. *romantisch*; Fr. *romantique*; Ital. *romantico*. (1) Having the characteristics of a mediaeval romance, i. e. marked by freedom of fancy in conception and form, and having for content deeds of adventure, or the expression of love or religious devotion.

(2) As given a more general application, and related to Fichte's doctrine of the Ego as supreme principle, romantic was set over against classic by the Schlegels and others. (a) Classic stands for the objective, for conformity to such laws as clearness, truth, unity. Romantic is subjective, 'the will or caprice of the poet admits no law above itself' (F. Schlegel). Fancy is unrestrained. (b) Classic emphasizes the TYPE (q. v.); romantic the individual and CHARACTERISTIC (q. v.). (c) Classic prefers REPOSE (q. v.); romantic makes feeling and passion primary, prefers the vague, mystical, and obscure to the clear and distinct, and is opposed to any laws, social, political, or moral, which would limit feeling or its full enjoyment.

(3) With Hegel the terms classic and romantic were used in a sense similar to (2), but with less emphasis on the capricious element of feeling. Classic art is that in which the idea is embodied in exactly adequate form, giving the ideal; romantic art has a more inward content, and so transcends any effort to embody it completely in sensible form. The term is applied by Hegel to modern art in general. Painting, music, and poetry are the romantic art forms.

(4) Present usage makes the characteristic of the romantic, subjectivism, the embodiment

of feeling, with more or less of the various sub-characteristics indicated under (2) above. 'Romanticism' is applied to varieties of this tendency, and to the Romantic movement and school (below).

Romantic movement. The movement of revolt against the modern classic (e. g. Pope in England, the French 17th and 18th century drama, &c.), beginning about the middle of the 18th century (Rousseau, Goethe, Byron, &c.), and including as later representatives Victor Hugo and Wagner.

Romantic school. A group of writers in Germany advocating the views of art and life indicated under (2). It included A. W. and F. Schlegel, Tieck, Novalis, Schleiermacher, and others.

Literature: J. H. SCHLEGEL, *Ueber den Begriff des Romantischen* (Wertheim, 1878; Programm); ZIMMERMANN, *Aesth.*, ii. 89-101; SCHASLER, *Gesch. d. Aesth.*, 777-826; HEGEL, *Aesth.*, ii. Th., 3. Absch.; WALLASCHKE, *Aesth. d. Tonkunst*, 282-9; VAN DYKE, *Princ. of Art*, chap. v; ROYCE, *Spirit of Mod. Philos.*, chap. vi; CARRIERE, *Die Kunst in d. Kulturentwicklung*, v; BRANDES, *Die Hauptströmungen in d. Litteratur* (1892); PHELPS, *The Beginnings of the Romantic Movement* (1893); KÖSTLIN, *Aesth.*, 170 f.; BEERS, *English Romanticism in the 18th Century* (1899); T. GAUTIER, *Hist. du Romantisme* (3rd ed., 1877); HERFORD, *The Age of Wordsworth* (1897); OMOND, *The Romantic Triumph* (1900); A. BIESE, *Die Entwicklung des Naturgefühls im Mittelalter u. i. d. Neuzeit* (2nd ed., 1892); J. E. SPINGARN, *Hist. of Lit. Criticism in the Renaissance* (1899); K. FRANCKE, *Social Forces in German Lit.* (2nd ed., 1897). (J.H.T.)

Romanticism: see ROMANTIC (2, and Romantic School).

Root (linguistic) [Icel. *rót*]: Ger. *Wurzel*; Fr. *racine*; Ital. *radice*. That part of a word which remains after all the formative elements recognizable by grammatical analysis have been removed.

Such formative elements are prefixes, suffixes, and inflectional endings. This analysis is purely formal, serving merely the purposes of scientific convenience, and asserts nothing concerning the original independent identity of these elements. In the earlier history of Indo-European comparative grammar the dogma of original monosyllabic root-words was generally accepted, but the present tendency of the science is to see in the stems, rather than in the roots, the type of the

primitive word. The nomenclature 'root,' 'stem,' representing originally a crude translation from the German Wurzel, 'root of a tree,' Stamm, 'trunk of a tree,' has now lost its force even in German. (B.I.W.)

Roscelin (Roscellinus, Rousselin, Rucelinus). Born in Lower Brittany about the middle of the 11th century. Studied at Soissons and Rheims; attached to the cathedral of Chartres; canon of Compiègne. He is called the founder of nominalism, because of his lifelong defence of a tri-individual doctrine of the Trinity. He was opposed by Anselm. He recanted in 1092, but continued his teaching. A second council condemned his opinions (1094), and he fled to England. Forced to return to France later, he taught at Tours and Locmenach (where Abelard was his pupil). Lived as late as 1121. See SCHOLASTICISM.

Rosenkranz, Johann Karl Friedrich. (1805-79.) Studied philosophy in Berlin and in Halle. Professor of philosophy at Königsberg, 1833-79. The 'best representative' of the Hegelian centre.

Rotation (sensation of): Ger. *Drehungsempfindung*; Fr. *sensation de rotation*; Ital. *sensazione* (or *percezione*) *di rotazione*. Sensation from the rotation of the body.

Rotation may be perceived by the eye, or if the movement be fast enough, by the organ of the STATIC SENSE (q. v.). Functionally regarded, the sensation of DIZZINESS (q. v.) may be termed the 'sensation of rotation' (see SENSATION). A common illusion of rotation, known as Purkinje's dizziness, is due to involuntary movements of the eyes. See ILLUSIONS OF MOTION AND MOVEMENT.

Literature: SANFORD, *Course in Exper. Psychol.*, expts. 47-50. (E.B.T.)

Rotation and Rotation Table: see LABORATORY AND APPARATUS, III. B, (c), (3).

Rothe, Richard. (1799-1867.) Studied theology and philosophy at Heidelberg and Berlin; preacher to the Prussian Embassy at Rome, 1823; professor at Wittenberg, 1828; at Heidelberg, 1837; at Bonn, 1849; again at Heidelberg, 1854, where he died. A follower of Hegel.

Roughness and Smoothness: Ger. (1) *Rauhempfindung* (and *Rauigkeit*), *Glattermpfindung* (and *Glätte*); Fr. (*sensation de*) (1) *rugeux* and (— *de*) *lisse, uni*, (2) *rude, inégal* and *égal*; Ital. (*sensazione di*) *ruvidità*, (— *di*) *liscio*. (1) Sensations of: the quality of CONTACT SENSATION (q. v.) arising from intermittent stimulation of the same skin-area, as from the unevennesses of an explored surface,

is roughness; continuous contact with movement of stimulus, of skin, or of both, has the quality of smoothness.

The surface is the usual case, and so customary that other intermittent contacts which fulfil the conditions, and are not apprehended in other ways, create the illusion of an uneven, or even, surface.

(2) Of tones: when tones sounded together produce BEATS (q. v.) not sufficiently rapid in succession to give a BEAT TONE (q. v.), and not sufficiently slow to be separately heard, they are heard as 'roughness.' See Sanford, *Course in Exper. Psychol.*, 79 a. Tones from which beats are absent are sometimes called 'smooth.' (J.M.B., H.C.W.)

Rousseau, Jean Jacques. (1712-78.) Born at Geneva, he was placed about 1722 in the family of a clergyman, sent 1723 to a notary, and afterwards to an engraver. Sent by a Roman Catholic priest to Madame de Warens at Annecy, she became the important factor in his life, 1729-38. During this time he studied for the priesthood, tried to teach music, wandered about much, but always failed. Went to Paris, 1741; secretary of the French ambassador to Venice, 1743; quarrelled with him and returned to Paris, where he devoted himself to literature. In 1765 his *Emile* necessitated his flight to England. His mind seemed affected, and he fled back to France and wandered from place to place, thinking he was pursued. In 1770 he returned to Paris, earning a livelihood by copying music, as he had done in youth; moved to the estate of a friend near Paris, 1777, where he died. His *Contrat Social* supplied the positive tenets of the French Revolution. He has been a principal figure in social evolution, as well as in the philosophy of the STATE (q. v.) and of society.

Royalty (in economics) [Med. Lat. *regalitas*, an attribute of the crown]: Ger. *Urheberrecht*; Fr. *droit de copie*; Ital. *prerogativa reale*. A charge authorized by the sovereign for the right to reproduce an idea, whether embodied in a mechanical invention (patent right) or in a work of literature or art (copyright).

No man will take the lead in a hazardous experiment when those who follow him have practically equal gain in case it proves successful, while avoiding the chance of loss in case of failure. The patent right, by making the gain a permanent one, makes it worth while for the capitalist to develop a new process which would otherwise go untried.

The monopoly conferred by copyright is justified on similar grounds. The royalty is not intended to reward the inventor *as an inventor*, but to make it worth while to risk capital, or to spend time and thought, in order to render the invention or production available for the public. (A.T.H.)

Rüdiger, Andreas. (1673-1731.) Born at Rochlitz in Saxony, he studied theology and jurisprudence at Halle, where Thomasius influenced him. He practised medicine and held positions as professor of philosophy alternately at Halle and at Leipzig.

Rudiment [Lat. *rudimentum*]: Ger. (1) *Anlage*, (2) *Rudiment*, *Spur* (see VESTIGE); Fr. (1) *rudiment* (cf. ANLAGE), *ébauche*, (2) see VESTIGE; Ital. (1) *rudimento* (cf. ANLAGE), *abbozzo*, (2) see VESTIGE. (1) In embryology: the first accumulation of cells in the embryo recognizable as the commencement of a structure, organ, or part.

(2) In anatomy and phylogeny: an incompletely developed part, as regards usually both size and structure.

There has been much discussion on the use of rudiment in embryology. Three other equivalents of ANLAGE (q. v.) have been proposed, 'fundament' by E. L. Mark, 'proton' by B. G. Wilder, 'primordium' by A. Willey. Of these none has been commonly used. The word *Anlage* is now generally used by American embryologists, and is also met with in British authors. (C.S.M.)

As rudiment seems the best rendering for *Anlage* (a term upon which all the authorities of this work agree—except C.S.M., who prefers to use the German term—and which the French and Italian correspondents also recommend in their respective languages) it would seem best to adopt some other term (see VESTIGE) for the anatomical meaning (2). Cf. TERMINOLOGY, German, '*Anlage*.' (J.M.B.)

Rudimentary (organs, &c.): see VESTIGIAL, and cf. RUDIMENT (2).

Ruin [Lat. *ruina*, from *ruere*, to tumble down]: Ger. *Verfall*; Fr. *ruine*; Ital. *ruina*. (1) Applied in theology to reprobation, damnation, punishment, &c., in the future life, whatever doctrinal form this may take on.

(2) In ethics it means confirmed moral disintegration and decay. Its connotation is not exact. (J.M.B.)

Rule [ME. *reule*, rule]: Ger. *Regel*; Fr. *règle*; Ital. *regola*. (1) A formula expressive of an approved mode of procedure. (C.S.P.—J.M.B.)

(2) A law pertaining to matters of detail,

especially the conduct of business or of a game.

(3) A formula expressing what is permissible, and how it should be done, as the rules of algebra.

(4) Any universal proposition, especially the major premise of a direct syllogism.

Antepredicamental rule. One of two rules in the prefatory part of Aristotle's *Praedica-menta*. The first is in substance the *dictum de omni*, namely: 'When one thing is predicated of another as its subject, whatever is said of the predicate may also be said of the subject.' The other rule is: 'The differences of different genera and of things not subordinate one to another are different.'

Rule of philosophizing. One of four rules laid down by Sir Isaac Newton in the beginning of the third book of his *Philosophiæ Naturalis Principia Mathematica*.

They are as follows:—

Rule I. As causes of natural phenomena (*rerum*) not more ought to be admitted than such as are at once true [whence the common phrase *vera causa*] and suffice to explain the observations.

Rule II. And therefore, for natural effects of the same class, the same causes are to be assigned, as far as may be.

Rule III. Physical characters which cannot be increased or diminished, and which belong to all bodies which it is possible to subject to experiment, should be held to be characters of all bodies.

Rule IV. In experimental science, propositions inferred by induction from observation ought to be held as true, whether exactly or approximately, without regard to contrary hypotheses, until new observations may correct them or establish exceptions to them.

The logical accuracy of these rules, especially of the last, is in contrast with the statements of many modern logicians. (C.S.P.)

Rule (ethical): Ger. *Regel*, *Norm*; Fr. *règle*, *norme*; Ital. *regola*, *norma*. (1) A specific practical precept, or maxim of conduct.

The mediaeval casuists tried to provide such specific rules for the direction of the individual conscience. Modern intuitionists have contented themselves with the discovery of general principles, leaving to the individual judgment the determination of their particular application. A recent classification and discussion of 'Rules of Conduct' is by Baldwin, *Social and Eth. Interpret.*, chap.

xiv.

(2) Some of the earlier British moralists use the term as synonymous with STANDARD (q.v.), criterion, or norm. Butler says of man: 'He hath the rule of right within; what is wanting is only that he honestly attend to it' (*Sermons*, iii. § 3). Cf. CASUISTRY. (J.S.)

Rule (legal): see LAW.

Rule of Faith (in theology) [Lat. *regula fidei*]: Ger. *Glaubensverordnung*; Fr. *règle de foi*; Ital. *regola, norma di fede*. The sufficient and final standard for the determination of truth in matters of religious faith and doctrine.

A conflict arose in Judaism as to the rule of faith; one party ascribing absolute authority to the written Scripture alone, while the other admitted oral tradition to equal standing with the written word. The same issue has arisen in Christianity between the Reformed and the Roman Catholic churches; the former adhering to the Bible as the only

standard, while the latter includes authorized tradition. (A.T.O.)

Ruskin, John. (1819-1900.) An English essayist and critic, born at London. Receiving his early education from private tutors, in 1836 he entered Christ Church, Oxford. The first volume of his *Modern Painters* appeared in 1843, and was at once effective in influencing English art and art criticism. Professor in the Cambridge School of Art in 1858, Rede lecturer at Cambridge, 1867; Slade professor of fine art at Oxford, 1869-79, and again, 1883-5. He established St. George's Guild in 1871. Died at his home, Brantwood, on Coniston Lake, in the Lake Country.

Ruysbroek, Johannes (also **Rusbrock, Rusbroch, &c.**). (1293-1381.) So called from the name of his native village Ruysbroek, near Brussels, he was (1317) priest and vicar of St. Gudule, Brussels. Retired to the Augustine monastery at Grünthal, 1353, where he became prior and died.

S

S — SACRAMENT

S (in logic). (1) In the mnemonic names of moods, *s* signifies that the proposition denoted by the preceding vowel is to be converted simply in reduction. See **CONVERSION** (in logic).

(2) Used for the subject of a proposition or the minor term of a syllogism. (C.S.P.)

σ [Gr. letter, sigma]. Symbol for .001 sec. in experimental psychology. See **REACTION TIME**. (J.M.B.)

Sabbatarianism [Lat. *sabbatarius*, pertaining to the Sabbath]: Ger. *die Lehre der strengen Sabbaths-Beobachter*; Fr. *sabbatisme*; Ital. *sabatismo*. The doctrine that the obligation to observe the Christian Sabbath rests on the divine injunction as expressed in the fourth commandment.

The Sabbatarian rejects the view which would rest the obligation of the Sabbath on relative grounds and claims for it the absolute divine command. Associated with Sabbatarianism, but not necessarily involved in it, is the tendency to overstrictness in its observance. On the other hand, the rejection of Sabbatarian views is often accompanied with a tendency to extreme laxity in the observance of the day. (A.T.O.)

Sabellianism: Ger. *Sabellianismus*; Fr. *Sabellianisme*; Ital. *Sabellianismo*. A theory of the Godhead, named after its founder Sabellius, in which the divine nature is conceived to be unitary both in substance and personality, the Trinity arising as a threefold but temporary manifestation of God in his relation to creation and the redemption and sanctification of man.

Sabellianism arose as a reaction against polytheistic tendencies and moved in the direction of extreme Jewish monotheism. It

asserts the essential oneness of the divine nature and person. The distinction into the trinadic manifestation is one of mode and not of nature. The Trinity is, therefore, a purely temporary manifestation, and disappears with the temporal death of Christ. The doctrine was condemned as a heresy at Alexandria in 261 A.D., but still survives as a tendency.

Literature: Schaff-Herzog's *Cyc.*, art. Anti-Trinitarianism; M. J. ROUTH, *Reliquiae Sacrae*; SCHAFF, *Hist. of the Christ. Church*, ii. 580 f.; *Church Hist.*, by MILMAN, MOSHEIM, &c. (A.T.O.)

Saccus: see AMMONIUS SACCUS, and ALEXANDRIAN SCHOOL.

Sacerdotalism [Lat. *sacerdotalis*, pertaining to the priest]: Ger. *Priesterwesen*; Fr. *sacerdotalisme*; Ital. *sacerdotalismo*. The theory that the characteristic functions of the minister of religion are sacrificial and priestly.

The sacerdotal character has been prominent in most religions in connection with the demand for propitiatory or expiatory sacrifice. In Christianity the great expiatory sacrifice has been made once for all by its Founder and great High Priest. The sacerdotal feature survives, especially in the Romish Church, in connection with the conception of the sacrament of the Eucharist as essentially a sacrifice requiring priestly mediation. Reformed Christianity rejects this sacrificial conception, and with it, to a great degree, the priestly conception of the minister of religion. (A.T.O.)

Sacrament [Lat. *sacramenta*, from *sacrare*, to dedicate]: Ger. *Sacrament*; Fr. *sacrement*; Ital. *sacramento*. A solemn rite of religion administered according to prescribed forms, which is supposed to carry with it the

divine sanction and to communicate needed grace to the believing recipient.

The sacrament is an incident of the sacrificial feature of religious worship, and varies with it. In Christianity it attains its maximum of importance and meaning in the Roman Catholic communion. Reformed Christianity tends to reduce the number as well as the importance of the sacraments relative to other features of worship.

Literature: Canons and Decrees of the Council of Trent; J. CH. AUGUSTI, *Denkwürdigkeiten aus d. christl. Archaeologie* (1827-31); CHEATHAM, *Dict. Christ. Antiq.* (1875-80). (A.T.O.)

Sacred Books: Ger. *heilige Schriften*; Fr. *livres saints*; Ital. *sacre scrittura*. See SCRIPTURES.

Sacrifice [Lat. *sacrificium*, an offering]: Ger. *Opfer*; Fr. *sacrifice*; Ital. *sacrificio*. An offering, consecrated and set apart for a religious purpose, which is solemnly offered according to prescribed forms to some object of worship as an act of propitiation, consecration, reconciliation, penitence, or thanksgiving.

For the sacrificial idea of SACRAMENT see that term; see also ATONEMENT. Sacrifice is employed to designate any expiatory act or suffering, as the sacrifice of Christ. But it also includes acts of religious service and devotion, as the giving of alms and the sacrifice of a broken and contrite heart. In general, however, sacrifice in the religious sense is associated with solemn and ceremonial forms. (A.T.O.)

Sacrifice of Christ: see ATONEMENT.

Sadduceeism [Heb. *Tsadok*, the Just One]: Ger. *die Lehre der Sadducäer*; Fr. *saducéisme*; Ital. *sadduceismo*. The doctrine of a school of Judaism (known as Sadducees) in the time of Christ who opposed the Pharisees in both religion and politics, rejecting the authority of the oral tradition and the ascetic formalism of the Pharisees, and favouring the introduction of foreign influences and ideas.

In modern times Sadduceeism has come to be a synonym for indifference in religion and the spirit of worldly compromise. The school or party no doubt originated among the Jews as a protest against the extreme rigidity of the Pharisees. It was at first distinctly religious, but in time was led to take a political attitude in opposition to the extreme conservatism of the Pharisees. In the time of Christ the dominating interests of the party were political rather than religious.

Literature: WELLHAUSEN, *Die Pharisäer und die Saducaei* (1874). (A.T.O.)

Saisset, Émile Edmond. (1814-63.) Born at Montpellier, and educated in Paris under Cousin and Jouffroy, he taught philosophy at Cahors, Caen, and Paris. In 1856 he succeeded Damiron at Paris, and retained the chair until his own death. He belonged, with Cousin, to the French Eclectic school.

Salisbury, John of (Joannes Parvus, also John of Chartres. (cir. 1110-80). Named from his birthplace Salisbury, England, he was educated in France, where he became the zealous pupil of Abélard. Returned to England, his native land, 1148, and became intimate with Theobald and Thomas à Becket. Bishop of Chartres, 1176-80.

Saltation (in biology) [Lat. *saltare*, to jump]: Ger. *sprunghafte Entwicklung* (K.G.); Fr. *discontinuité, saccade, saut*; Ital. *evoluzione saltuaria* (or *a salti*). 'The phrase "evolution by saltation" has been used for the sudden appearance of divergent types, first used by W. H. Dall' (Hyatt, *Science*, Jan. 29, 1897, 170).

Similar conceptions are covered by the terms 'transilient' (Galton) and 'discontinuous' variation (Bateson), and MUTATION (q. v.). (J.M.B.)

Saltus [Lat., a jump]: Ger. *Sprung*; Fr. *saut*; Ital. *salto*. (1) Saltus in concludendo: a paralogism which consists in proving something as an aid in proving something else and then supposing that something different has been proved. But by some writers a mere omission of an obvious step in a proof is called a saltus.

(2) A 'saltus in change' is defined by Kant as a passage from one state to another without passing through a continuous line of intermediate changes. (C.S.P.)

Salvation [Lat. *salvatio*, from *salvare*, to deliver]: Ger. *Erlösung*; Fr. *salut*; Ital. *salvazione, salute (dell' anima)*. The deliverance which religion promises from the sins and sufferings and imperfections of the present life. See SOTERIOLOGY.

In Christianity it is provided in the Christian scheme of redemption, and to a less degree in Buddhism in the ascetic discipline and the attainment of Nirvana.

Literature: see SOTERIOLOGY, BUDDHISM, NIRVANA, and ORIENTAL PHILOSOPHY (India). (A.T.O.)

Same (the) and (the) **Other**: Ger. (*das Gleiche und (das) Andere*; Fr. (*le même et (le) différent*; Ital. (*il medesimo e (l') altro*). These terms, with sameness and otherness, are corre-

lates which have their technical meaning as translations of certain terms in the Platonic philosophy—being otherwise equivalent to the terms **IDENTITY** and **DIFFERENCE**, **PERMANENCE** and **CHANGE** (q.v.). Plato used the term *ταὐτότης* (*taútótē*) for sameness.

Self-sameness is the characteristic sign of the Idea, the essential Being; while the material, having movement as its defining feature, is in continual change or process, a fact which is expressed by calling it the Other (*τὸ ἕτερον* = *hétéron*). The Sophist (254–60) aims to show that logically the Same and the Other require each other; and thus to refute the Eleatic conception of pure Being. According to Timaeus (35–8, and 44), God made the soul (the World soul primarily) by taking the Same (which is indivisible and unchangeable) and mixing it with the Other (which is divisible and has to do with material things), and then mixing them both with existence. This mixture was then subdivided according to complicated mathematical principles; the various proportions and positions of the Same and the Other account for the peculiarities of the universe (e.g. the uniformity of the stellar heavens, and the regular irregularity of the planetary), and also for the possibilities of true knowledge and of certain belief. This identification of the logical principles of identity and difference with the cosmic principles of permanence and change, reinforced by mathematic speculation upon the **ONE** and the **MANY** (q.v.), had great influence upon the later Neo-Platonic theories of the constitution of the world. Hegel revived the conception of the Other (*das Andere*) as expressing the Non-Being, involved in every Somewhat (*Etwas*) or defined Being (*Dasein*), constituting its finitude and its intrinsic tendency to change (*Veränderung*). Thus nature is the other of spirit, and as such is otherness in itself and to itself, and thus a world of space and time (Hegel, *Werke*, iii. 115–8). (J.D.)

Sameness (consciousness of): see **IDENTITY**.

Sanchez, Francis. (1562–1632.) A Portuguese, educated at Bordeaux. Professor of medicine in Montpellier, 1584; of medicine and philosophy in Toulouse until his death. Like Montaigne and Charron he was a sceptic.

Sanctification [Lat. *sanctificatio*, from *sanctus*, holy, and *facere*, to make]: Ger. *Heiligung*; Fr. *sanctification*; Ital. *sanctificazione*. In Christian theology, the process by which the sinner who has repented and

been justified through faith, is gradually purified from the corruption of sin and made holy.

Sanctification presupposes the atonement, and the repentance, faith, and justification of the sinner. It stands correlated with conversion, which is grace begun in the human heart; whereas sanctification is the process by which the work of grace is completed. The nature of sanctification is somewhat differently conceived by Protestants and Roman Catholics; the former distinguishing it more specifically from justification, and laying the greater emphasis on the agency of sovereign grace; the latter practically identifying justification and sanctification, and emphasizing more the penance and good works of the believer.

Literature: see **THEOLOGY**. (A.T.O.)

Sanction (ethical) [Lat. *sanctus*, sacred]: Ger. *Sanktion*, *Handlungsbegründung* (psychological—Barth); Fr. *sanction*; Ital. *sanzione*. Any influence, whether negative or positive, whether of the nature of punishment or of reward, which enforces the observance of the moral law, or stimulates to such observance. In general, however, as a result of juristic influence, the term has been largely restricted to its negative sense of punishment. Cf. **DUTY**.

The doctrine of moral sanctions is specially prominent in the Utilitarian school. Bentham regards pleasure and pain as not only final, but efficient causes. As efficient causes, or as capable of giving a binding force to any law or rule of conduct, pleasure and pain are termed sanctions. Bentham distinguishes four such sanctions: the physical, the political, the moral or popular, and the religious. According to J. S. Mill: 'The question is often asked, and properly so, in regard to any supposed moral standard: What is its sanction? What are the motives to obey it? Or more specifically: What is the source of its obligation? Whence does it derive its binding force?' Mill distinguishes the internal from the external sanctions. The latter are—'the hope of favour and the fear of displeasure from our fellow creatures or from the Ruler of the Universe, along with whatever we may have of sympathy or affection for them or of love and awe of him, inclining us to do his will independently of selfish consequences.' 'The internal sanction of duty, whatever our standard of duty may be, is one and the same—a feeling in our own mind, a pain, more or less intense, attendant on violation of duty, which, in properly cultivated moral natures, rises, in the more serious cases, into shrinking

from it as an impossibility: this feeling, when disinterested, and connecting itself with the pure idea of duty, . . . is the essence of Conscience. . . . Its binding force consists in the existence of a mass of feeling which must be broken through in order to do what violates our standard of right, and which, if we do nevertheless violate that standard, will probably have to be encountered afterwards in the form of remorse.' 'This basis of powerful natural sentiment' constitutes 'the strength of the Utilitarian morality. This firm foundation is that of the social feelings of mankind, the desire to be in unity with our fellow creatures.' Spencer follows Mill in differentiating the internal or properly moral control from the external or pre-moral controls which are preparatory to the moral, and from which the latter gradually frees itself. The moral control consists in the insight into the intrinsic superiority, as principles of conduct, of the more complex, representative, and later-evolved feelings to the simpler, presentative, and earlier-evolved. The sense of duty, so far as coercive, is the product of the pre-moral controls, and decreases with the increasing moralization of conduct.

Literature: BENTHAM, *Introd. to Mor. and Legisl.*, chap. iii; MILL, *Utilitarianism*, chap. iii; SPENCER, *Princ. of Eth.*, Pt. I. chap. vii. (J.S.)

Sanction (legal). That by which a law is enforceable.

'The real meaning of all law is that, unless things proceed in the manner prescribed by it, the state will, either of its own accord or if called upon, intervene. The intervention of the state is what is called the "sanction" of law' (Holland on *Jurisprudence*, chap. viii. 76). *Civil sanctions* are for the redress of civil injuries; *penal sanctions* are for punishing crime. A law without a sanction is imperfect (see Markby's *Elements of Law*, chap. xix). *Pragmatic sanctions*: in late Roman law, an imperial decree relating to the affairs of a community (*Cod. Theodos.*, xvi. 5, *de Haereticis*, 52); in modern law an ordinance by the sovereign authority concerning objects of the first importance as to the civil or ecclesiastical administration, especially that of Charles VII of France touching the liberties of the Gallican Church.

In early societies sanctions are of a moral character, coming from reverence for the gods, custom, and public opinion; or else arbitrary, coming from private vengeance

or royal will (see Maine's *Early Hist. of Inst.*, lect. ii. 30). The idea of law probably precedes that of sanction. 'Law is enforced by the state because it is law: it is not law merely because the state enforces it' (Pollock on *Jurisprudence*, chap. i. 27). 'Sanctae quoque res, veluti muri et portae civitatis, quodammodo divini iuris sunt; et ideo nullius in bonis sunt. Ideo autem muros sanctos dicimus, quia poena capitis constituta est in eos qui aliquid in muros deliquerint. Ideo et legum eas partes, quibus poenas constituimus adversus eos qui contra leges fecerint, sanctiones vocamus' (*Inst. of Just.*, ii. 1, *de Rerum Divisione*, &c., 10). Yet there is difference of opinion as to this relation. See PUNISHMENT, and JUSTICE. (S.E.B.)

Sanction (in psychology). Any ground or reason for action, whether or not the individual is conscious that this is his ground or reason. Cf. SANCTION (ethical, legal, social).

It seems to be impossible in the present state of discussion to confine this term to negative reasons, in accordance with the legal usage whereby sanctions are mainly penalties and not rewards. Both psychologically and philosophically these two classes stand on the same plane with reference to the individual's action: both enter to influence him from the point of view of consequences. In law the distinction is of more or less importance, since by penalties more enforcement can be given to a command than by rewards; but when we consider that both enter as preliminary data, deterrents or inducements, into the actor's mental life, this difference is seen to be principally, if not only, one of degree. As a matter of fact, law has actually developed a system of punishments rather than one of rewards, probably under the necessities of compulsion, such as imprisonment, &c.

From the psychological point of view the important distinction is not that between deterrent and inducing sanctions, but between conscious and non-conscious sanctions; which means between the sanction as end, on the one hand, and as a lower form of motive on the other, the latter being, perhaps, an influence of the affective or suggestive order which the individual does not apprehend at all. Many of the most important of the social sanctions are of the last-named sort; e.g. public opinion, custom, style, crowd action, &c. The following classification of sanctions, mainly with reference to this type of social influences, has been drawn up by the present writer with

greater detail elsewhere (*Social and Eth. Interpret.*, chaps. ix, x) :—

Sanctions	1. Personal (psychic)	<ul style="list-style-type: none"> S. of impulse. Lower hedonic S. S. of desire. Higher hedonic S. S. of right.
	2. Social (psychological)	<ul style="list-style-type: none"> Natural S. Pedagogical and conventional S. Civil S. Ethical and religious S.

Following the distinction recommended elsewhere (see PSYCHIC OR MENTAL AND PSYCHOLOGICAL), group (1) of the table above may be called psychic or mental, in so far as the sanction as such enters into the mental state of the actor. In so far as not entering into the actor's mental state as conscious reasons or motives for action, but still being reasons for his action, the sanctions of group (2) are psychological, but not psychic. The particular cases may work from one group to the other, notably from group (2) to group (1).

Literature : titles given under the other topics SANCTION ; AUSTIN, *Province of Jurisprudence*. More psychological are STEPHEN, *Sci. of Eth.*, chap. iii ; BAIN, *Mor. Sci.*, chap. ii ; BALDWIN (as cited above). (J.M.B., G.F.S.)

Sanction (social). Any means by which society induces the individual to act in accordance with the general will of the community.

Originally sanction was the act of making sacred ; hence later, making sacred by binding, as by an oath ; still later, making solemnly authoritative, as by a decree ; and finally, the penalty attached by law to an illegal act. From this last conception we have the notion of the social sanction, i.e. any penalty which society attaches to conduct that public opinion or common sentiment condemns, or any reward or distinction that society confers for conduct generally approved. Strictly speaking, all legal sanctions are included in social sanctions, which comprehend not only ridicule, public blame and praise, socially conferred distinction or office, boycotting, but also such penalties as fines, imprisonment, and death inflicted by common consent and by concerted action, whether legally or illegally. Cf. the other topics SANCTION. (F.H.G.)

Sanguine [Med. Lat. *sanguinitas*, blood-relationship] : Ger. *sanguinisch* ; Fr. *sanguin* ; Ital. *sanguigno*. Of a hopeful TEMPERAMENT (q. v.). (J.J.)

Sanity (and **Sane**) [Lat. *sanitas*] : Ger.

Gesundheit (*gesund*) ; Fr. *santé* (*sain*) ; Ital. *sanità*, *salute* (*sano*). Soundness of mind ; the possession and control of normal mental faculties. Cf. INSANITY. (J.J.)

Sankhya Philosophy : see ORIENTAL PHILOSOPHY (India).

Satan [Heb. *Satan*, an enemy] ; Ger. *Satan* ; Fr. *Satan* ; Ital. *Satana*. A name used in the Hebrew and Christian Scriptures for the great adversary who is represented as a fallen Archangel. See DEVIL.

Literature : CARUS, *Hist. of the Devil* (1901). See also DEVIL. (A.T.O.)

Satisfaction [Lat. *satis*, enough, + *facere*, to make] : Ger. *Befriedigung* ; Fr. *satisfaction* ; Ital. *soddisfazione*. Happiness arising from a conscious condition of wellbeing usually connected with the gratification of (i.e. the attainment of the end of) some particular sentiment.

So far as satisfaction is contrasted with happiness, it is (1) by limitation to the more settled or dispositional sources of pleasure. We get happiness from the gratification of lesser desires, but satisfaction from the consciousness of well-directed sentiments, such as friendship, intellectual endeavour, the successful issue of a thought-out plan, &c. We speak of ethical and aesthetic satisfactions where the term happiness would not be appropriate. (2) By the relative degree of conscious reflection or contemplation which is given to the pleasurable state and its object. A happiness may become a satisfaction or a gratification when we think upon it and remark its value to us. We take satisfaction in thinking upon situations which at the first gave us happiness. Gratification, as a term, is closely akin to satisfaction, having in it rather more emphasis on the first distinguishing mark noted above, and also more emphasis on the thought of self. This latter appears in the gratification of such emotions as pride, vanity, ambition, &c. (J.M.B.)

Butler speaks of 'happiness or satisfaction' (*Sermon*, xi. § 6). Hobbes, on the contrary, opposes happiness and satisfaction. 'The felicity of this life consisteth not in the repose of a mind satisfied. For there is no such *finis ultimus*, utmost aim, nor *summum bonum*, greatest good, as is spoken of in the books of the old moral philosophers. Nor can a man any more live, whose desires are at an end, than he whose senses and imaginations are at a stand. Felicity is a continual progress of the desire, from one object to another, the attaining of the former being

still but the way to the latter. The cause whereof is that the object of man's desire is not to enjoy once only and for one instant of time, but to assure for ever the way of his future desire' (*Leviathan*, chap. xi). Cf. Mill's distinction between happiness and contentment (*Utilitarianism*, chap. ii). The term is also sometimes used as equivalent to pleasure, or the constituent element of happiness. Shaftesbury, e. g., speaks of 'pleasures or satisfactions' (*Inquiry concerning Virtue*, Bk. II. Pt. II. § 1). Green and other Neo-Hegelians use the term 'self-satisfaction,' as well as 'self-realization,' to characterize the good—holding that the self is satisfied only by being realized. Cf. Green, *Prolegomena to Ethics*, Bk. III. chap. i, and Spinoza, *Ethica*, Pt. IV. prop. 52. (J.S.)

Satisfaction (aesthetic). (1) SATISFACTION (q.v.) in what is aesthetic.

(2) The term is specially connected with the principle of the 'satisfaction of expectancies,' in accordance with which an aesthetic content will be so constituted that its various parts lead naturally up to one another, as if in response to a definitely formulated expectation.

This phrase is Marshall's, who follows closely after Bergmann in his development of the idea borrowed from Schiller in connection with beauty of form.

Literature: BERGMANN, Ueber das Schöne (1887); MARSHALL, Aesth. Princ. (1895).

(J.R.A.)

Saturation [Lat. *saturare*, to fill]: Ger. *Sättigung*; Fr. *saturation*; Ital. *saturazione*. The correlative term to purity of colour; the relative deficiency in black-white admixture in any colour sensation. (C.L.F.)

It is the third determinant of the total colour impression, besides colour tone and brightness. It is sometimes spoken of as the colour intensity of the 'colour.' Cf. Visual Sensation under VISION, and BRIGHTNESS.

(E.B.T.)

Satyriasis: see NYMPHOMANIA.

Savage [Lat. *silvaticus*, belonging to a wood, through Fr.]: Ger. (*der*) *Wilde*; Fr. *sauvage*; Ital. *selvaggio* (man), *selvatico* (animals)—(E.M.) Pertaining to the lowest condition of normal human development.

Owing to the various connotations of a derogatory character which attach to the word savage, the term 'primitive man' is preferred by many writers; this includes as well the prehistoric races whose status must be inferred from their relics, as well as the

crudely organized tribes visited by modern travellers.

Owing to the essential differences of habitat, race, endowment, &c., it is impossible to describe any group of mental qualities or of industrial and social status as characteristic of savages; but it may be said that their implements and industries are simple adaptations of natural materials; that the search for food, or the warfare with neighbouring tribes, occupies a prominent part of their occupation; that their moral and religious life is largely built up on animistic conceptions of the forces of nature; that their mental life is limited and monotonous, and their social organization crude and often conditioned by nomadic habits. It has been customary in comparative psychology to compare mental characteristics in the child with those of savages; the analogy is suggestive, but the difference in physical development between the two must not be lost sight of. It has been customary to contrast savagery with barbarism, and these with civilization. However useful in current speech, these distinctions of large and variable culture stages are too indefinite to be scientifically precise. Cf. CULTURE, RACE, and ANTHROPOLOGY. (J.J.)

Savart's Wheel: see LABORATORY AND APPARATUS, III, B, (b), (4).

Saving Faith: see FAITH for equivalents of that term. In Christian theology, that act on the part of the repentant sinner by means of which or in which the atoning grace of Jesus Christ is secured and appropriated and the sinner justified before God. Cf. FAITH. (A.T.O.)

Saviour [Lat. *salvator*, from *salvare*, to deliver]: Ger. *Heiland*; Fr. *Sauveur*; Ital. *Salvatore*. One who delivers or provides a way of deliverance from the evils and imperfections of the present existence.

In the broad sense, Zoroaster, Buddha, Mohammed were saviours, inasmuch as they were the authors of schemes of deliverance from the evils of life. But none of these claim to save by his own power. They either profess to be prophets of God, like Mohammed, or, like Buddha, point out the way which men must realize in their own strength. In Christianity, on the contrary, the Saviour also professes to be divine and to save by his own power; the Christ of Christianity not only points out the way, but promises divine help and grace in its realization. (A.T.O.)

Scent (or **Odour**) [Lat. *sentire*, to per-

ceive]: Ger. *Geruch*; Fr. *odeur*; Ital. *odore*. A specific sort or quality of SMELL SENSATION (q.v.).

(J.M.B.)

Scepticism [Gr. *σκέψις*, doubt, hesitation, from *σκέπτεσθαι*, to look at carefully, to scrutinize]: Ger. *Skepticismus*; Fr. *scepticisme*; Ital. *scetticismo*. (1) The theory that positive and certain truth is not attainable by the human intellect; or (2) the theory that it is necessary to doubt before reaching truth.

As scepticism denotes a certain mental attitude or temper, or method of attacking philosophical problems, the purely formal definition is worth even less than are most terms which characterize philosophical systems. It varies from dogmatic assertion of unbelief, uncertainty, and the impossibility of attaining truth, to the most nicely balanced doubt which will not even assert that all is doubtful, into thoroughgoing subjection of all philosophical concepts to disbelief until rational grounds can be found for them. In this last sense it is opposed to dogmatism, rather than to theories of the impossibility of true knowledge. In this sense scepticism has been at least an implicit factor in all independent philosophy; it has been asserted by some (Descartes) to be the necessary preliminary to all philosophic belief, and by others (Hegel) to be a necessary moment in the complete self-evolution of every philosophic idea and system.

Very different motives have also contributed to the development of the sceptical attitude. There is (1) the strictly *philosophical*. This is generally evoked as reaction from highly dogmatic systems; and it endeavours, by criticizing their premises and methods, to show their entire untenability. This *motif* is reinforced, as a rule, by the fact that different dogmatic systems hold quite contrary views, and the arguments of one may be turned against those of another until they mutually demolish one another. Thus the opposition of the schools of Heraclitus and Parmenides was a great factor in calling out the scepticism of the SOPHISTS (q.v.). Moreover, the rapid appearance of diverse and incompatible systems produces a psychological condition of unrest and satiety of system which is highly favourable to scepticism.

(2) The *ethical*. A dogmatic system of thought tends to develop an over-positive and strenuous disposition in action, a temper which insists upon carrying its universals into all the details of conduct, and of imposing them upon others. It is the basis of political

and theological exclusiveness and persecution. This is met by pointing out the fallibility and relativity of all such principles, leading to the consequent position that 'probability is the guide of life.' Hence the necessity of tempering even the most general principles in action by adaptation to circumstances, a moral opportunism; and as regards the conduct of others, of pursuing a policy of toleration. This motive, while not often explicitly stated, has perhaps been the animating spark of the most influential scepticism. It is certainly the chief motive of the scepticism of the middle Academy. It influenced also the school of sceptics headed by Pyrrho, but was overshadowed in him by another ethical motive — that imperturbability (complete balance, to give a somewhat too positive interpretation) is attainable only as the outcome of complete doubt, and this is the pre-condition of complete and undisturbed happiness. Cf. SCHOOLS OF GREECE, and PYRRHONISM.

(3) The *religious*. To do away with the capacity of reason for attaining substantial spiritual truth has been a favourite way of proving the necessity of a revelation of such truth, and establishing the incapacity of reason to impeach this truth when revealed. This motive influenced the Latin fathers of the Church, was active in mediaeval thought, the nominalistic theory of twofold truth (see SCHOLASTICISM) being only the explicit statement of what after all was a logical presupposition of the orthodox philosophy. Its most celebrated modern adherent is Pascal; but the point of view appears in another form in Mansel's *Limits of Religious Thought*, and, combined with other *motifs*, is contained in Balfour's *Foundations of Belief*.

(4) The *culture point of view*. This is generally united with the first and second tendencies, and arises from the feeling that dogmatism of thought is not compatible with wide learning and with the polite and urbane temper. It made itself felt in the Academics, particularly in Cicero. Montaigne is its consistent and delightful representative in modern thought; Hume is touched by it; while secondary philosophic writers, like Matthew Arnold, are quite sure to be permeated with it.

The arguments adduced in ancient thought for scepticism may be summed up as follows:

(1) The relativity of the senses: in man and animals; in different men; in the same man in different conditions; among the different senses at the same time. (2) The relativity

of objects: dependent upon the medium; upon position and distance; and manifest in their constant change and dissolution. (3) The relativity of belief and opinion: customs, manners, fundamental moral and religious beliefs differ radically in different peoples. (4) The reasoning process itself is intrinsically inadequate, because all demonstration depends on prior assumptions or premises, and so on *ad infinitum*—the exact converse of the reasoning which made Aristotle assume ultimate unproved or self-evident premises—the axioms. The writings of Sextus Empiricus (about 200 A.D.) were a summary of all ancient arguments, and exercised great influence upon thought after the revival of learning.

Modern scepticism, as in Hume, draws freely upon the ancient arguments, and yet has a distinct colouring of its own. It consists largely in turning the senses and reason, as the two supposed sources of knowledge, against each other, as with Hume; and attempts by an analysis of the process and elements of (supposed) knowledge as such, rather than by accumulating particulars, to show its inherent incapacity to reach valid conclusions. It has thus been an indispensable factor in the evolution of the modern theory of knowledge. Indeed, the chief difference appears just here. Ancient scepticism acted simply as a check, or as resource to minds that could not accept the dogmatic systems. It reacted *from* them, but not *into* them; they continued practically unaffected, save in details. Modern scepticism has been an integral factor in constituting not merely the form, but the content of modern thought. In this general sense, at least, Kant's assertion that CRITICISM (q.v.) unites dogmatism and scepticism, and Hegel's contention that sceptical doubt is an immanent factor in all philosophizing, must be accepted.

Scheiner's Experiment: Ger. *Scheiner'scher Versuch*; Fr. *expérience de Scheiner*; Ital. *esperienza dello Scheiner*. An experiment in ocular accommodation, illustrating

the formation of double images in the single eye. A needle is observed monocularly through two pinholes in a card, separated by a less distance than the diameter of the pupil. The arrangement has been employed in optometry (Helmholtz, *Physiol. Optik*, 2nd ed., 128), and, by Czermak, for colour mixture (*ibid.*, 351).

Literature: SCHEINER, *Oculus*, 1619; SANFORD, *Course in Exper. Psychol.*, expt. 106; WALLER, *Human Physiol.* (1891), 420. (E.B.T.)

Schelling, Friedrich Wilhelm Joseph von. (1775-1854.) Educated at Tübingen in theology, philosophy, and philology. Went to Leipzig (1796) and studied mathematics, natural science, and medicine for two years. Began lecturing in Jena as a colleague of Fichte. Became editor of the *Zeitschrift für speculative Physik*, 1800; professor in Würzburg, 1804; secretary of the Academy of Arts and Design in Munich, 1808; lecturer in Erlangen, 1820-6; professor of philosophy in the University of Landshut, 1826; called to Berlin, 1841. See IDEALISM.

Schema [Gr. *σχῆμα*, a diagram]: Ger. *Schema*; Fr. *schème*; Ital. *schema*. (1) The product, in the Kantian philosophy, of the exercise of the transcendental imagination in giving generality to sense and particularity to thought. See SCHEMATISM.

(2) A mode of construction; a formula for synthesis which as formula or method is general, but as embodied or acted upon is particular. Thus the triangle, or circle, to the geometer, is schematic. An image which illustrates a method of space construction (Kant, *Krit. d. reinen Vernunft*, 126-30 of Müller's translation).

The schema of quantity is number; of a reality is the continuous and uniform production of degrees of sensation; of substance is permanence in time; of causality, succession of manifold in time so far as subject to rule; of reciprocity, coexistence of the manifold in time so far as subject to rule. Democritus used the term *schemata*, *σχήματα*, to denote the characteristic forms of his atoms. It was also employed to designate the figures of the Aristotelian syllogism. (J.D.)

Schematism: Ger. *Schematismus*; Fr. *schématisation*; Ital. *schematismo*. The theory, in the Kantian analysis of knowledge, of the use of the transcendental imagination as mediating between sense and understanding.

Kant pushed his dualism between sense and understanding, or more strictly between the matter of intuition and the concepts or

functions of discursive thought, to such an extreme as to require a connecting bit. The former is immediately given, or received, in sensibility; it constitutes the material of knowledge, is manifold, and in itself is blind and unordered. The latter has only mediate reference, is an active and unifying process, and in itself is empty, i. e. is lacking in objective content and validity. Kant seems to have thought at first that the *a priori* forms of perception, space, and time would suffice to order the otherwise chaotic material of sense. At least, they are treated in the *aesthetic* as given and complete in themselves. But in the *analytic* it became apparent that space and time forms themselves had to be construed by means of the synthetic functions of thought. It also became obvious that the concepts needed to be imaged in order to exist even as definite subjective thoughts, to say nothing of acquiring valid objective reference. Hence the need of a go-between to overcome the heterogeneity of the two factors in all knowledge, a go-between, moreover, which is necessary even for the formally distinct existence of each factor. This was found in the pure or transcendental imagination which constructs the pure logical concepts in relation to the function which they perform in ordering time elements (the moment, duration, and succession). Time is like thought, as *a priori*; like sensibility as a manifold; and thus it possesses characteristics which render it homogeneous with both, and which fit it for occupying an intermediate position. Thus the schematism of the pure understanding 'treats of the sensuous conditions under which alone pure concepts of the understanding can be used' (Kant, *Critic of Pure Reason*, Pt. II. Bk. II. chap. i; see 119-24 of Müller's translation). (J.D.)

Schiller, Johann Christoph Friedrich von. (1759-1805.) German poet and critic. Educated in law and medicine in the new Carlsschule at Stuttgart. Appointed military surgeon to a regiment in that city, he ran away when ordered to desist from writing poetry, concealing himself for a year near Meiningen. He became dramatic poet for the Mannheim theatre; went to Leipzig and Dresden with Körner, 1785; visited Weimar and met Goethe, 1787; professor of history at Jena, 1789; formed Goethe's friendship about 1794; moved to Weimar, 1800; was ennobled, 1802, by Emperor Francis II.

Schilling, Gustav. (1815-72.) Born and educated in part at Köthen, he began

the study of medicine in the Nikolaischule at Leipzig, but was won over to the study of Herbartian philosophy by Drobisch and Hartenstein. In 1840 he became Privatdocent at Giessen; professor extraordinary in 1846; and professor ordinary in 1851. He died at Giessen.

Schism [Gr. *σχίσμα*, a cleft]: Ger. *Schisma*; Fr. *schisme*; Ital. *scisma*. A breach within an ecclesiastical organization, caused by differences regarding doctrine or discipline, which leads to the formation of the dissenting party into a separate body.

The term schism, which etymologically signifies a split within a body, according to current usage is applied only when the breach has resulted in secession and separate organization. A schismatic is any one who promotes divisions which threaten secessions. (A.T.O.)

Schlegel, Friedrich. (1772-1829.) Educated at Göttingen and Leipzig; lectured (1801) in Jena, and (1802) in Paris; studied oriental languages in Paris; joined the Roman Catholic Church, 1808; settled in Vienna, where he lectured and wrote until his death. A native of Hanover, he was a historian of art, aesthetics, and philology.

Schleiermacher, Friedrich Ernst Daniel. (1768-1834.) Born at Breslau, he attended the Pedagogium of Niesky and the Barbyseminary of the United Brethren; studied theology at Halle; private tutor and assistant preacher before 1796; after 1796 preacher for the *Charité* in Berlin; court chaplain at Stolpe, 1802; assistant professor of theology in Halle, 1804; preacher in the church of the Trinity, Berlin, 1809; professor at Berlin, 1810; secretary of the Academy, 1814. Cf. RELIGION (philosophy of, and psychology of).

Schmid, Leopold. (1808-69.) Born at Zürich; studied at Tübingen and Munich; professor of theology in the seminary at Limburg, 1831; at Giessen, 1839; elected bishop of Mainz, but Pope Pius IX refused to confirm him on account of his liberal views; left the theological, and entered the philosophical faculty at Giessen, 1867.

Scholastic: see LATIN AND SCHOLASTIC TERMINOLOGY, SCHOLASTICISM, and PATRISTIC PHILOSOPHY, and cf. VERBAL.

Scholasticism (the Schoolmen) [Lat. *scholasticus*, trans. of Gr. *σχολαστικός*, from *σχολάζειν*, to lecture, to be master of a school]: Ger. *Scholastik*, *scholastische Philosophie*; Fr. *philosophie scolastique*, or simply *scolastique*; Ital. (*la*) *scolastica*. (1) The

name of the period of mediaeval thought in which philosophy was pursued under the domination of theology, having for its aim the exposition of Christian dogma in its relations to reason. See HISTORY OF PHILOSOPHY, and LATIN AND SCHOLASTIC TERMINOLOGY.

(2) Any mode of thought characterized by excessive refinement and subtlety; the making of formal distinctions without end and without special point.

Scholasticism is distinguished, on one hand, from Arabian philosophy (see, however, lower down) carried on outside the pale of the Church; and from MYSTICISM (q.v.), which is found within the Church paralleling Scholasticism. The latter emphasizes logical and formal processes; as the former, feeling and inner experience. Charlemagne founded schools of learning all over France, which was, thereafter, the special home of learning and of science. The teachers were termed *doctores scholastici* (Ueberweg, *Hist. of Philos.*, i, according to whom the use of the term may be traced back to Theophrastus), while the wandering scholar-teachers from the mission schools of the Church were termed *scholastici* (Erdmann, *Hist. of Philos.*, i. 288). They were ecclesiastics, so it is not a matter of surprise that they philosophize wholly in the interests of the Church. The language is Latin. The method is comment upon and exposition of selected passages of Scripture and the early logicians, and finally of the Church fathers and Aristotle. They combined with their strictly philosophic pursuits all the science and culture of their age (in the *Trivium* and *Quadrivium*). Cf. PATRISTIC PHILOSOPHY.

The schools were founded in the 8th century, but it is not till the 9th that specifically philosophic thought appears. While in one sense scholasticism still continues as the official teaching of the Roman Catholic Church, its dominance and its independent career ceased with the Renaissance and the 15th century. The intervening five centuries are conveniently divided into three sub-periods: (1) the formation of scholasticism, formulation of its problems; (2) its systematization; (3) its decline. The three periods may also be characterized by their reference to antiquity. The first was based upon fragments of Aristotle's logical writings and Neo-Platonic commentaries; the second is due to systematic acquaintance with Aristotle; the third to the humanistic revival of all

ancient learning, which, even when honouring Aristotle, gave him a freer interpretation.

I. In the first period, Scotus Erigena is in many respects nearer to the mystics than to the scholastics proper, and is pantheistic in his theology. He is influenced chiefly by the Neo-Platonists rather than by Aristotle. But in two respects he is extremely important for scholasticism in the narrower sense. (a) He asserts the essential identity of the content of faith and reason, and in the most immediate way. Any dictum of authority is reasonable, and every rational principle may be considered as dogma; true religion *is* true philosophy, and vice versa. The problem thus raised of the relation between the two is of determining importance for the entire period. (b) He assumes a complete parallelism of the hierarchy of being on one side, and thought on the other, proceeding from the most universal to the most particular; the former comprehends and produces the latter. Creation is equivalent to the logical unfolding or making explicit of the supreme universal, from God down, in a graded scale of beings, to the individual things of sense—the lowest form of reality. This might be termed the deductive process. On the other hand is the eternal return to God—i.e. the logical inclusion of the particulars again in the universal, the inductive movement. This involves, as applied to man, the theory of redemption, immortality, &c. Now the significance of this is not only in its frankly stated REALISM (q.v., 1), but in the use of this realism to state and explain the fundamental doctrines of the Church—those of creation, the Trinity, sin, and redemption.

In this connection the discussion becomes one of tremendous import—of the relation of God as the universal to the individual, to man. When separated from this relationship, the whole realistic-nominalistic discussion degenerates into formal subtleties and refinements. It is Anselm who carries out in a systematic and reflective way the philosophical statement of all the dogmas of the Church, and who sees in realism the only justification of the supreme authority of God, of the doctrine of the Trinity, and asserts that nominalism is only the deification of sensible things. It also leads him to the ONTOLOGICAL ARGUMENT (q.v.). Roscelin, as a nominalist, had shown that its effect on theology is to substitute a doctrine of tritheism for the Trinity, while Berengar

had used it to attack the doctrine of transubstantiation. Thus the doctrine was brought under the ban of the Church. But the statement of realism as a theory of the divine nature and of creation revealed the essential difficulties in it. Admitting that the universals are the real in the mind of God, and the archetypes of all created things, the problem arises as to just how these are related to the things of the sensible world. The doctrine easily lent itself to a pantheistic interpretation or absorption of individuals in God. This tendency was evident in William of Champeaux and also in Bernard of Chartres. It also led to the conclusion that since the class as substance is in all the individuals it includes (these being indeed only its accidents), one and the same substance must have mutually contradictory attributes. Hence Abélard attempts a mediation of these extreme views in a realistically tempered conceptualism. This theory was long completely victorious, and put to rest this strife, appearing satisfactory both theologically and logically.

But as to the other problem raised by Erigena, Abélard leaned decidedly to the side of reason; he attributes to it a decisive, not merely a formalizing power, and criticizes the fathers freely, bringing out their contradictions not to show how they may be nullified, but in order that reason may get at the truth of the matter—the *real* content of faith. So far as the logical movement is concerned, we find it after this time carried on in a highly rationalistic theology, as in Gilbert of Poitiers, and in the development of that system of argumentative distinctions which is still to some minds the chief characteristic of scholasticism. This brought out a reaction—a condemnation of all dialectic; and the assertion of the content of faith as supreme above all reason, as in Hugo, and still more the VICTORINES (q. v.)—following a more or less mystic path and occupied mainly with the anthropology of the inner religious life. John of Salisbury reacts in another direction, and occupies himself with a psychological examination of the questions which, on their logical side, had gone to seed in empty formalism—questions of the relation of sensation, perception, and understanding in arriving at concepts, and the psychical relations of faith, opinion, and knowledge; and also with scholarly synopses of previous thought.

II. The second period is not only richer in content, but much clearer in its main features.

The struggle with oriental Mohammedanism and the outcome of the crusades resulted in opening Europe not only to Arabian philosophy with its interpretation of Aristotle, but also to Arabian and Jewish science, much wider and more exact than was occidental, and systematized, after the Aristotelian fashion, by relation to metaphysical principles. The period commences accordingly in the 13th century; and while in the early part of this century the writings of Aristotle are condemned by the Church, in the next century Aristotle stands on practically the same level with Augustine, the greatest of the fathers, and is officially declared to be the forerunner of Christ in natural matters, as John the Baptist was in matters of grace, and is known, briefly, as *The philosopher*. The writings of Aristotle were made known in their completeness; not simply the logical treatises—in fragmentary form at best. The scholastic method gets shape, consisting first in the breaking up of the text discussed into a number of propositions; secondly, questions are raised, and the variety of possible answers set forth; thirdly, arguments, *pro* and *con.*, are adduced in a syllogistic chain, leading to a conclusion. The logical distinguishing or dialectic, so developed in the previous period, and yet having little or no aim outside itself, now becomes a useful instrument, and is handled with great power, being reinforced by the more substantial parts of the Aristotelian logic. When we apply this apparatus, both of the substance—metaphysics, physics, psychology, and ethics—and form—the modified logic, or dialectic of thought—to the service of the doctrines of the Church (themselves the richest summary in existence of spiritual and ethical experience), we have the scholastic philosophy of this period, of which Windelband (*Hist. of Philos.*, 311) says it was ‘an adjustment and arrangement of world-moving thoughts upon the largest and most imposing scale history has known.’

Alexander of Hales, Albertus Magnus, and St. Thomas Aquinas are the greatest of many names here. The first develops the method in a practical way, as a help to the orderly exposition and demonstration of dogma; the second develops it in a theoretical way, and as applied to the entire philosophy of Aristotle as well as to the dogma of the Church; while the third makes an organic fusion of the two factors, and thus brings the movement to its culmination. As to the content of their philosophy, it must be borne

in mind that Arabian Aristotelianism was conceived in a Neo-Platonic sense. It was pantheistic in tendency, denying the transcendence of the absolute reason or God; holding to the eternity of matter, 'creation' being the realization of potentiality, not a distinct act of effecting the world out of nothing; and denying the individual immortality of the soul. Hence Albertus and St. Thomas must, while adhering to Aristotle, justify the doctrines of the transcendent and creating God, and the immortal individuality of the soul, as distinct from its realistic absorption in deity. Cf. ST. THOMAS (philosophy of).

The Aristotelianism of these men produced a reaction, of which Duns Scotus is the leader: Bonaventura and Eckhart are classed among the mystics. Their controversy concerned three points in particular: (1) the relation of faith to reason; (2) the relation of intellect and will; (3) the nature of individuality.

(1) In spite of (or, better, because of) the conviction of Albertus and St. Thomas as to the relation of Aristotle to Church dogma, they are compelled to set aside certain doctrines as simply the products of revelation, utterly inaccessible to the natural mind—it being clear that Aristotle had not taught the doctrine of the Trinity or the Incarnation, &c. (In this period, as in the earlier one, it was the mystics who, drawing on Neo-Platonism, attempted a speculative construction of these doctrines.) They are above reason, but not contrary to it. The natural light can lead to certain truths, the content of natural religion and morality; but above this is supernatural religious and ethical truth, which is 'of grace,' not of nature, and is revealed, not discovered. This, the so-called doctrine of the *twofold truth*, is the basis of the teachings of Albert and St. Thomas. But having gone so far, it is difficult not to go further; and here is the rift in the lute which finally destroys the unity of scholasticism. Duns Scotus (generally regarded as the most acute philosophical mind of the period) held that theology was only a practical matter, aiming at salvation from sin, having to do with the will, not the intellect, while philosophy is pure theory. Each is right in its own sphere. The doctrine was conceived in good faith in order to give to dogma a claim untouched by reason; for Scotus was acute enough to see that if reason can assist or confirm theology, it can also attack or criticize it. But its actual effect was in the other direction. Reason was given greater scope and stringency;

all sorts of propositions, theologically heretical, were proved, with the pious clause (sometimes in good faith, sometimes not) that though this was so according to reason, the opposite was true according to faith.

(2) The same insistence upon the practical side is found in the psychology and ethics of Scotus. While St. Thomas followed the Greek position which uniformly made knowledge, contemplation, identity of subject and object in rational intuition, higher than the will, Scotus followed Latin thought, which had found its religious expression in St. Augustine. The will, according to the Thomists, is determined by the good, which is discerned, both in general and in particular cases, by the reason (see PERSEITY); moreover, reason has an objective metaphysical significance, an intrinsic relation to truth. But Scotus gives a psychological, or historical, account of knowledge; it is a natural process, and hence, if the will is dependent upon it, it in turn is really determined by nature with its necessity. Hence the will, as self-included power of choice, is really fundamental. God is free, because of the radical primacy of the will. He created the world out of his sheer will, not in conformity to prescriptions of reason—a position which, of course, dovetailed excellently into the separation of theology from philosophy. Moreover, salvation is not the eternal vision or contemplation of God, but a state of will—love—superior to contemplation.

(3) The emphasis upon reason tends to leave the individual in a precarious condition, for it is connected with the Greek realism, the assertion of the higher reality of universals. While Aristotle had held to God as a transcendent individual, as pure form, Averroës had insisted that there is no form without matter, and thus developed a pantheistic theory. St. Thomas here, as in his theory of the sphere of grace and of nature, attempted to establish an equilibrium. In the immaterial world, pure and *subsistent* forms are real and active without any attachment to matter; while in the material, forms are realized only in matter (are *inherent*). Now man belongs to both worlds: as rational soul, he is the lowest of pure immaterial forms; as animal soul (having body), he is the highest of the other type. And in man both of these are bound together into a single unity—the only form which is both subsistent and inherent. But St. Thomas had also to deal with differences of personality—the so-called *principium*

individuationis. God is absolute genus and individual at the same time, and uniquely so. Each angel is relative genus and individual in one. But different human individualities have but one genus. Their differentiation is due to the determination of matter, to distinctions of time and place; hence they are substantialized only through their relations to definite bodies. Against this view, which seemed to them to deny spiritual and ethical individuality, the Scotists protested. According to them, the individual soul, *qua* individual or differentiated, is a self-subsistent reality, and is not a mere determination of a genus (see REALISM, 1).

III. There are both intrinsic and, relatively speaking, extrinsic reasons for the break-up of scholasticism. Intrinsically, in Thomism it reached its culmination. After reason and faith had each received its exact position, and reason had been used wherever possible to demonstrate faith, and when this was not possible, to show that, at least, the dogma was not contrary to reason, the scheme was virtually complete. To develop it was to transform it. And the Scotist teachings threatened in a more active way the unity of the system. This happened not only by emphasizing the rights of reason within the theoretical world, but by its assertion of the reality of the individual soul, which easily developed—as in William of Occam—into extreme nominalism, the doctrine that only individuals are anywhere real. Moreover, this led to empiricism, for while the universal can be apprehended in thought, the individual (as even Scotus had taught) must be met with in experience to be known. Moreover, Scotism had everywhere a more psychological colouring than Thomism, and by furthering reflection in empirical psychology, went far to usher in a new way of thinking. The external causes (stimulated, however, by these intrinsic ones) were HUMANISM (q. v.), the revival of learning, and the newly awakened interest in nature, with its daughter, mathematical and physical science. The latter finds its forerunner in Roger Bacon and its expression in Copernicus and Galileo. With them, the natural world of the scholastics, so intimately bound up with their metaphysics and theology, is destroyed, and a new order of conception ushered in.

Literature: of the histories of philosophy, ERDMANN is unusually full in this period; and WINDELBAND (who has been largely followed) is noteworthy in his seizing upon

main problems and streams amid all the diversity of writings—a thing more difficult in Scholasticism than elsewhere. PRANTL'S *Gesch. d. Logik* is the authority on the logical side. The art. 'Scholasticism' in the *Encyc. Brit.* is an excellent summary. As general histories, we have HAURÉAU, *Hist. de la philos. scol.*; KAULICH, *Gesch. d. skol. Philos.*; and STÖCKL, *Gesch. d. Philos. d. Mittelalters*. See also ST. THOMAS (philosophy of). (J.D.)

Schoolmen (theology of the): Ger. *Lehre der Scholastiker*; Fr. *théologie scolastique*; Ital. *teologia degli scolastici*. The religious system developed by the Schoolmen of the middle ages, having for its characteristic aim the translation of the dogmas of the Christian faith derived from Scripture and tradition into a body of organized scientific knowledge by means of the application to them of the concepts and processes of philosophical reflection. See PATRISTIC PHILOSOPHY, SCHOLASTICISM, and ST. THOMAS (philosophy of).

The scholastic movement begins properly with the 11th century and extends on to the Reformation. Its differentiating characteristics as a theological movement are (1) its assumption of the Church dogmas as absolute and indisputable truth; (2) its introduction of philosophy, principally the dialectical system of Aristotle as an instrument for the translation of the proposition of faith into one of rational knowledge. Beginning practically with Anselm, the great Schoolmen include the names of Roscellinus, William of Champeaux, Abélard, Bernard of Clairvaux, Peter Lombard, John of Salisbury, Alexander of Hales, Bonaventura, Albertus Magnus, Thomas Aquinas, Duns Scotus, Roger Bacon, William of Occam, Raymond of Sabunde, and Nicholas of Cusa. The scholastic movement is divisible into two great periods, separated by the Arabian revolution of the 12th century, which placed a fuller knowledge of Aristotle at the disposal of European scholars.

Literature: HAMPDEN, *The Schol. Philos. considered in its Relation to Christ. Theol.* (London, 1838); THOMASIIUS, *Dogmengeschichte des Mittelalters* (Erlangen, 1870); TOWNSEND, *The Great Schoolmen of the Middle Ages* (London, 1882); histories of philosophy, UEBERWEG and ERDMANN. See also SCHOLASTICISM. (A.T.O.)

Schools of Greece: Ger. *Philosophenschulen der Griechen*; Fr. *écoles philosophiques de la Grèce*; Ital. *scuole filosofiche dei Greci*. (1) In a looser sense, the various groups of

SCHOOLS OF GREECE

Greek thinkers, allied by race, locality, or opinion, e. g. Ionics, Sceptics.

(2) In a stricter sense, the more or less definitely organized groups which had personal relationship as a more or less fundamental element, and carried on joint labours under a recognized head or 'scholarch.' The ideas of some founder, such as Plato or Epicurus, were thus defended and elaborated by successive generations of the school.

I. The more important schools in the narrower sense may be grouped under three periods, Pre-Socratic, Socratic, and Post-Socratic. To the first belong (1) the Milesians, located at Miletus, comprising Thales, Anaximander, and Anaximenes, of the 6th century B.C. Heraclitus of Ephesus (about 536-470 B.C.) is often grouped with them under the general term Ionic school. (2) The Pythagoreans, of Crotona in Italy, founded by Pythagoras of Samos (born about 580 B.C.), and having Philolaus of the next century as the most prominent philosopher. (3) The Eleatics, of Elea in Italy, together with Xenophanes (of Colophon, born about 570 B.C.; his connection with Elea is doubtful), Parmenides (who wrote about 470 B.C.), and Zeno (about 490-430 B.C.); Melissus of Samos shared Eleatic views. (4) The Atomists, of Abdera in Thrace, of which Leucippus and Democritus (about 460-360 B.C.) are the leading members, although Protagoras (about 460-410 B.C.) went out from this city also. All the above, as well as Anaxagoras of Clazomenae (about 500-430 B.C.), who founded a school at Lampsacus, were Ionians. For their theories see PRE-SOCRATIC PHILOSOPHY. In the second half of the 5th century B.C. the schools or philosophical societies, with the exception of the Pythagoreans and the school of Abdera, gave place to the freer and more public discussion which characterized the teaching of the SOPHISTS (q.v.) and of Socrates.

II. The second period is that of Socrates (469-399 B.C.) and the Socratic schools. Socrates himself conducted his discussions in so public a manner that he could hardly be said to have a school. But his disciples founded several, each claiming to represent the teaching of the master. For Plato and his school, the Academy, as well as Socrates, see SOCRATIC PHILOSOPHY, and below.

The other Socratic schools were: (1) the school of Megara (the Megarians or Eristics), founded by Euclid, which applied the Eleatic metaphysics to the Socratic principles, maintaining the good to be the

only being, and asserting that the actual and the possible are one. Eubulides, Alexinus, Diodorus Cronus, and Stilpo were members of the school, which was famous for its skill in 'eristic' or polemic, with a use of catch-questions and logical subtleties. Little is known of (2) the Elean-Eretrian school founded by Phaedo of Elis, which lasted but a short time, and had Menedemus as another member. (3) The Cynic school (named from the gymnasium Cynosarges, in which it was conducted) was founded by Antisthenes. Starting from the principle that virtue is the only good, the school argued that virtue must therefore make man independent of fate and fortune. It must then consist in freedom from wants—in living in a 'state of nature.' Diogenes is the famous representative of this. (4) The Cyrenaic school, founded by Aristippus of Cyrene, maintained that the good is to be found in pleasure. The Socratic element manifests itself in the doctrine that the completest pleasure can be gained only by intelligent insight and appraisal. This led to a preference of mental over bodily pleasure by later members of the school (Anniceris). Hegesias drew a pessimistic conclusion. The Epicureans were the heirs of the Cyrenaic teaching. See HEDONISM.

III. In the third period are included the most celebrated schools: (1) The *Academy* (from a grove and gymnasium named from the hero Academos), at first, as (a) the 'Older Academy,' developed Plato's teaching, especially on the ethical side, and combined with it the Pythagorean number theory; then, as (b) the Middle Academy, under Arcesilaus (about 315-241 B.C.) and Carneades (214-129 B.C.), was an exponent of SCEPTICISM (q.v.); and finally, in (c) the New Academy, under Philo of Larissa (about 100 B.C.) and Antiochus, turned to dogmatism and eclecticism. Plato's doctrines were later studied and developed in the form known as NEO-PLATONISM (q.v.) at Alexandria by Ammonius (175-250 A.D.) and Plotinus (204-69 A.D.), and also in a Syrian school founded by Iamblicus (died about 330 A.D.). Neo-Platonism at Athens was represented by Plutarch (died about 120 A.D.) and Proclus (411-85 A.D.). Damascius was head of the Academy when it was closed by the Emperor Justinian in 529 A.D.

(2) The *Peripatetic* school, founded by Aristotle (384-322 B.C.) was located in the Lyceum, a gymnasium sacred to Lycaean Apollo (Lycaeus, a mountain in Arcadia). The school was named from the shady walks

(*περίπατοι*) in which Aristotle talked with his disciples. Theophrastus (370–287 B.C.) and Strato, his successor, as head of the school, maintained and developed Aristotle's theories, but the school was especially active in literary, historical, and scientific studies. In ethics the school maintained a less extreme view than either Stoics or Epicureans, holding that external goods are necessary for the attainment of complete wellbeing, although, on the other hand, virtue is worthy to be sought for its own sake, and other goods without virtue are valueless.

(3) The *Stoic* school, founded at Athens by Zeno of Cyprus (about 340–265 B.C.), was so named from the porch (*Στοά Ποικίλη*) where Zeno taught. Of Zeno's successors, Cleanthes is known as the author of a hymn to Zeus, and Chrysippus (died 206 B.C.) for his extraordinary productivity, and for the ability with which he systematized and defended the Stoic principles. The Stoic principles proved especially congenial to Roman thinkers, to whom they were presented especially by Panaetius (cir. 180–111 B.C.), with more or less of an eclectic adoption of ideas from other schools. Seneca (4–65 A.D.), Epictetus (cir. 100 A.D.), and Marcus Aurelius Antoninus (Emperor 161–180 A.D.) represent a Stoicism modified by religion. The doctrines of the school will be treated below in connection with those of the Epicureans.

(4) The *Epicurean* school was founded by Epicurus (341–270 B.C.) and conducted in the gardens of the master. Many works of Philodemus, a contemporary of Cicero, were found at Herculaneum, but the best known literary representative of the school is the Roman poet Lucretius (98–54 B.C.). The school was noted for the personal friendships which it fostered, and for the strictness with which it adhered to the founder's doctrines. It continued as late as the 4th century, and its principles were taken up and reproduced for the modern world by Gassendi (1592–1655).

The Socratic philosophy had (a) grown out of an attempt to interpret the life of Greek culture at its height. (b) It was given a dualistic development by Plato under the influence of the cult of Dionysus. It was partially restored to a philosophy of 'this world' by Aristotle, but the Platonic influence remained manifest in the very conceptions through which reality was conceived. (c) In this development the theoretical interest was always present, and in Aristotle assumed the commanding position. The Stoic and Epicurean schools represented a different

attitude in each of these three respects. (i) Greek civic life had disintegrated. The rich artistic and political activity of the citizen had given place to the quest for a measure of happiness for the individual. (ii) The Stoic harked back to the more primitive animistic view of the world, especially in the form in which this was presented by Heraclitus (see PRE-SOCRATIC PHILOSOPHY), and the Epicureans took up a negative attitude towards all religious conceptions. (iii) The dominant aim in both Stoic and Epicurean schools was practical. Theoretical interests were kept entirely subordinate.

(a) The common problem of both schools was—How can the individual lead a happy life? The Greek demand for intelligence, especially as formulated in the philosophy of Socrates, led both schools to give a common formal answer to their problem in their ideal of the sage—the wise man who knows the true good. Further, the political uncertainties, and the change from an attitude of boundless hope and thirst for achievement to an attitude of accepting certain limitations as inevitable, found expression in both systems in certain qualities of the ideal sage. He must above all be independent of the world's fortunes. This meant that he must be master of his own emotional life, for it is only through the feelings that we are at the mercy of events. Repose, imperturbability, apathy are the conditions most prized. But in defining how this shall be attained, the ways part. The Epicureans, following the Cyrenaics, seek this peace by a choice of the calmer pleasures, especially those of friendship and culture, by avoiding political or other responsibilities, and by freeing the mind from superstitious fears of the gods and the future. Far from teaching a coarse sensualism, Epicurus maintained that a wise man would not allow himself to become the slave of violent desires or passions; he will remain master of himself. The Stoics, on the other hand, maintained that the sage shows his wisdom, not in distinguishing *between* pleasures—as if feeling were after all the only good—but in maintaining the supremacy of reason as *against* feeling. The controlling or ruling faculty is the most important part of man. To obey reason is to 'follow nature'; to keep reason ever supreme is the chief excellence or virtue, and virtue is the only good; to overcome the world means to be completely free from passions or emotions. This is 'apathy.'

(b) The Stoic and Epicurean views of nature

stood in close connection with their ethical ideas. Epicurus found in the atomic theory of Democritus a view of the cosmos which offered a purely mechanical theory, and was hence adapted to banish superstitious dread of the unseen. The only important deviation from the earliest atomism was the assumption that to form the first complexes, the atoms deviated voluntarily from a straight line of fall. 'Voluntarily' here means 'without cause,' and the same conception of uncaused action was applied by Epicurus to the choice of the will (see FREEDOM). The Stoics, on the other hand, developed the primitive animistic theory of the cosmos in such a way as to make their conception capable of being characterized at once as pantheism and as materialism. This was effected through the conception of the PNEUMA (q. v., see also PSYCHE), which was on the one hand the all-pervading and animating spirit or life of the universe, and on the other was still a material substance, a finer air or fiery breath. In this pneuma each individual shares. Accordingly, to follow nature means not merely to follow human nature's highest principle of reason, but to conform to the all-pervading and controlling principle of the world, to the divine law or LOGOS (q. v.) which characterizes the pneuma in this its rational aspect.

Resignation to destiny, voluntary conformity to the on-going of the world, was thus given a rational motive, and with many took on the distinctly religious aspect of submission to the divine ordering of events. The early emphasis upon the control over the individual by some system or authority had retreated into the background in the presence of the search for a principle which should be first good and therefore binding. In the Stoic system this emphasis is restored in the conception of 'duty.' Further, this conception of participation in a common world-reason favoured the conception of man as a social being and a citizen of a world-state—a philosophic ideal which Cicero and later Roman thinkers applied to the Roman Empire. The law of this universal state is the 'law of nature,' i. e. of the universal reason. The Epicureans consistently held an individualistic view of the state, regarding it as formed by a 'compact' to supply human wants. Finally, in defending their view of the world as controlled by reason, the Stoics developed the leading arguments of TELEOLOGY (q. v.), while the Epicureans refused to admit their validity.

(c) As respects the problems of logic and epistemology, the Stoics and Epicureans were forced to assert some criterion as against the SCEPTICS (q. v.). Both schools assume that all knowledge comes from sense-perceptions. The Epicureans made the clearness or vividness of these the test. The Stoics found a further basis for the value of certain general conceptions in their metaphysical theory that the various human spirits or pneumata are emanations from the one world-pneuma. Ideas common to all men—*communes notiones*—may be presumed to be true. This theory as transformed into the doctrine of 'innate ideas' long remained influential. The Stoics also asserted the distinction between ideation and JUDGMENT (q. v.), and recognized in this latter a volitional element.

MUNRO, 1886); MASSON, Atomic Theory of Lucretius (1884); GUYAU, La Morale d'Epicure (1878); works of SENECA, EPICETUS, and M. AURELIUS. See also under the titles HEDONISM, PYRRHONISM, NEO-PLATONISM, SOCRATIC PHILOSOPHY; and reports of recent literature on the earlier period by DIELS and WELLMANN, and on the later period by JOEL, in the Arch. f. Gesch. d. Philos. (J.H.T.)

Schopenhauer, Arthur. (1788-1860.) Born at Danzig, his father a banker, he studied at Göttingen, under the sceptic Schulze, being specially interested in Kant and Plato; heard Fichte in Berlin, 1811. Received the doctorate, 1813. Moved from Weimar to Dresden (1814-8), where he wrote his most important works. He made

two journeys into Italy, and two unsuccessful attempts (1820 and 1825) to lecture on philosophy at Berlin. After 1831 he lived in retirement at Frankfort-on-the-Main. See VOLUNTARISM, and OPTIMISM AND PESSIMISM.

Schopenhauerism (or **-eanism**): Ger. *die Schopenhauer'sche Philosophie*; Fr. *Schopenhauerisme*; Ital. *Schopenhauerismo*. (1) The philosophy of Schopenhauer. (2) VOLUNTARISM (q. v.). (J.D.)

Schubert, Gotthilf Heinrich. (1780–1860.) Naturalist and philosopher, educated at Jena and Leipzig. He became professor of natural science at Erlangen.

Schulze, Gottlob Ernst. (1761–1833.) An opponent of Kant. Born at Heldrungen in Thüringen. Professor at Göttingen after 1810.

Science [Lat. *scientia*, knowledge]: Ger. (1) *Wissenschaft*, (2) *Naturwissenschaft*, *exakte Wissenschaft*; Fr. *science*; Ital. *scienza*. (1) Knowledge; in particular, knowledge in the eminent sense as the outcome of the systematic and trustworthy functioning of the cognitive processes. Systematic co-ordination and certainty have, therefore, often been specified as the notes of science.

In this sense the term may be used of knowledge as a whole, or of any branch or department of knowledge which is so far ordered and reliable that it is entitled to the name. Distributively (or in contrast to philosophy, see below), the various subordinate branches of knowledge are known as the sciences, the particular sciences, the special sciences, &c.; and various distinctions are drawn in definition of the differences among them. The formal sciences are contrasted with the sciences of content, and pure science with applied science. The exact sciences are those which admit of precise quantitative treatment. Physical science or the physical sciences, material science or the material sciences, deal with the facts and laws of the physical world; the terms natural science and the natural sciences have an equivalent meaning, except when they are employed, as becomes increasingly the case, to cover the knowledge of the psychical as well as of physical nature (cf. NATURAL, and see NATURALISM, 3).

Mental science is generally used as a synonym for psychology, and, especially since the differentiation of psychology from philosophy, for empirical, in distinction from rational, psychology; it is also employed, but the practice is obsolescent and of doubtful propriety, in designation of philosophy. In a similar way, moral science may denote

empirical and speculative ethics, sometimes practical science or practical philosophy in all their several divisions. Philological science, historical, political, or social science, metaphysical science, theological science, &c., are further illustrations of the comprehensive significance of the term according to its etymology and historical usage.

(2) In a more limited sense, empirical science or the empirical sciences, positive science or the positive sciences, or science without qualification, signify that form of investigation which confines itself to phenomena and the laws of phenomenal reality, together with the results of such investigation. This type of thought is also called inductive science, experimental science, &c.; while, in a looser way, physical science, natural science, &c., have been used to designate it in consequence of the prominence of the sciences of material fact in the historical development of empirical inquiry.

Various accounts have been given of the relation of philosophy to the particular sciences, and to science in the restricted sense. The distinction between them has been made to depend on the partial and more concrete character of the special sciences, in contrast to philosophy as general and universal science; on the functions of philosophy in determining the boundaries of the particular sciences, in discussing the logical and epistemological principles which they imply, and, especially, in framing a critical synthesis of their results; on the fact that science abstracts from the relation to the knowing subject as well as from the ideal aspects of thought and being; on the 'merely hypothetical validity' of science, whereas philosophy has to do with 'ultimate reality'; on the limitation of science to phenomena over against the relation of philosophy to ultimate and to transcendent problems, &c. But whatever view is adopted, there is now a much larger measure of agreement than in previous times in recognizing the intimate and vital connection of the two forms of knowledge. See PHILOSOPHY, CLASSIFICATION OF THE SCIENCES, BIOLOGICAL SCIENCES, MENTAL AND MORAL SCIENCES, PHYSICAL SCIENCE, MATHEMATICS, ETHICS, PSYCHOLOGY, and SOCIAL SCIENCE. (A.C.A.Jr.)

The characteristics of exact or experimental science—apart from its inductive procedure—are (1) the use of measurement, giving quantitative statements of results, and (2) the reduction of more complex to more simple

groups of phenomena, the latter being accomplished mainly by experimentation. These characteristics are realized in the physical sciences, where the conservation and transformation of energy permit the use of exact units of measurement. Here the mathematical principles of substitution, continuous change, and deduction apply. So soon, however, as we come to the natural or biological sciences, the use of measurement is subject to a remarkable limitation. Transformation of energy has not been made out and no exact units of quantity have been determined. The fact of growth presents difficulties to the theory of change, because organic groupings seem to have inherent principles of development. So far as natural science has gone in being quantitative, it is mainly for purposes of classification. The difficulty is in part surmounted by the resort to the theory of probability, vital phenomena in many cases being treated as variations, and their laws of distribution, relative frequency, &c., investigated by the theory of ERRORS (q. v.). Cf. VARIATION (statistical treatment of).

This difficulty goes deeper also; it affects the results of experimentation. The analysis which it is the main utility of experiment to afford cannot be adequate or really explanatory without units of exact statement; that is, the analysis of a more complex group into a more simple group of phenomena must show that all the elements of the former are statable in certain units of the latter. But without vital units of measurement this cannot be done. No stage of subsequent growth is adequately stated in terms of earlier growth. The best that can be done is to get a series of curves of variation for the different stages (say the height of children of 8, 9, &c., years) and investigate the relation of these curves to one another. When that is done, the results are, or may be, laws of growth, but they do not state the analysis of the higher stages in terms of the lower, nor of either in terms of elementary units.

In view of these limitations of quantitative measurement and of experimental analysis, the biological sciences may be described as evolutionary or genetic. Genetic statements largely take the place of quantitative statements. The attempt to reduce vital changes to redistribution of matter in motion under mechanical principles has been made in a schematic but altogether hypothetical way. If it be ever done it will be an achievement

of chemistry; but when we remember that not only the cycle of the individual life with its infinite chemical compositions and decompositions must be accounted for as occurring in a single system, but with it occur the combinations of systems in reproduction, and the projection of new vital systems in heredity—a sort of returning upon itself of life at birth-nodes—we find an undertaking before which even the investigation of the celestial system pales into insignificance. When we talk of a chemical or mechanical explanation of life, we forget that life is a system, and that to explain it we must have a principle by which we can not only account for all its minute phenomena, but predict them all as well. Cf. BIOLOGICAL SCIENCES.

In much the same sense PSYCHOLOGY (q. v.) and ETHICS (q. v.) are genetic; they present certain peculiar features which remove them even more widely from the quantitative sciences. Cf. MORAL SCIENCES. (J.M.B.)

Scientific Method: Ger. *wissenschaftliche Methode*; Fr. *méthode scientifique*; Ital. *metodo scientifico*. The general method of successful scientific research. The following are some of its characteristics. Cf. SCIENCE.

(1) The student's first step is to form a perfectly definite and consistent idea of what the problem really is; then he ought to develop the mathematics of the subject in hand as far as possible; and to establish a mathematical method appropriate to the particular problem, if it be one which allows exact treatment. As examples and models of what is meant, may be mentioned Maxwell's researches on colour sensation in the *Philos. Trans.* for 1860, Flinders Petrie's book *Inductive Metrology*, the last chapters of Pearson's *Grammar of Science*. Of course, as the student's understanding of the matter advances, he will return to this first task, and continually improve upon his first essays.

The second step will be to consider the logic and methodetic of the research in hand, unless it is itself a question of pure mathematics, where the logic is inseparable from the mathematics. He will do well to study the manner in which questions somewhat analogous to his own have been successfully resolved in widely different fields; for the greatest advantage has accrued from the extension of methods from one subject to a widely different one, especially from simple to intricate matters.

The third step should be to reform his metaphysics, if the question is a broad one. Perhaps he thinks he has no metaphysics, and does not wish to have any. That will be a sure sign that he is badly handicapped with metaphysics of the crudest quality. The only way to disburden himself of it is to direct his attention to it. But he cannot reduce himself to anything like absolute scepticism in metaphysics without arresting his work. [This is especially true and important for psychologists.—J.M.B.]

The fourth step will be to study the laws of the phenomena dealt with, so far as they can be made out at this stage. The general order of discovery in the nomological sciences is first to pick up the phenomena by excursions in those fields in which they are to be found, with alertness of observation, with those clear ideas that makes the new fact instantly recognizable as new, and with the energy that seizes upon the faint trace and follows it up. Witness the manner in which all the new phenomena of radiation have been brought to light during the last generation: cathode rays, X rays, Becquerel rays, etc. After making some acquaintance with the phenomena, the next discovery is of their laws (nomological). In the light of one's metaphysics and general conception of the department of truth dealt with, one considers what different hypotheses have any claims to investigation. The leading considerations here will be those of the 'economics' of research. If, for example, a hypothesis would necessitate an experimental result that can be cheaply refuted if it is not true, or would be greatly at variance with preconceived ideas, that hypothesis has a strong claim to early examination. But one must not give up a hypothesis too readily. Many a discovery has been missed by that fault. Gravitation would have been known a decade earlier if Newton had not hastily thought it refuted, and so set back all the subsequent history of physics by something like that amount of time lost. It is

likely that thousands of persons more will die of consumption—as remote as that may seem—than would have died if he had not made that error. The testing of the hypothesis proceeds by deducing from it experimental consequences almost incredible, and finding that they really happen, or that some modification of the theory is required, or else that it must be entirely abandoned. The law of the phenomena once made out, it only remains to measure with precision the values of the coefficients in the equation which expresses it.

The problem under investigation may not be of a nomological kind. Not that the phenomena are not conceivably subject to law, so that the subject may ultimately be received into the nomological sciences,—as chemistry, for example, promises some day to mature into a nomological science; but in the present state of knowledge the question, we will suppose, cannot be so studied. Still, a certain amount of nomological study is a necessary preliminary to engaging with the problem itself. Biology calls for aid from physiology. The student who is studying the growth of languages must avail himself of all the knowledge that there is about the physics of speech sounds. In case, then, the question has not yet reached the nomological stage, the sixth step in the work will be of a classificatory nature. Such order, of a more or less imperfect kind, as can be traced in the phenomena must be made out. Students of the classificatory sciences like to call such regularities laws. The tendency is a symptom of health; because it shows that law is their ideal, and that they are striving to bring their sciences to the nomological stage. But such orderlinesses as 'Grimm's Law' (see GENDER) and 'Mendeléeff's Law' are not laws in the sense in which the association of ideas and the three laws of motion are laws. They are not satisfactory for a minute. They are nothing that can blend with our metaphysics; they are not of a universal kind; and they are not precise. You may imagine that there might be a chain of more and more universal, precise, and reasonable regularities leading from these to those. But there is, in fact, a great gap, which has to be acknowledged. A hypothesis may be made about the cause of the three laws of motion; but we can have no present hopes of satisfactorily proving the truth of such a thing; while we at once set to work with great hopes of making considerable steps towards explaining Mendeléeff's Law and Grimm's Law. But the most important dis-

inction between true laws and such regularities lies in the very different way in which we proceed to the discovery of the one and of the other. The whole attitude of mind is so different that it is difficult to believe that the same man would have great success in the two tasks. We have seen in our day the establishment of a grand example of each kind, the Law of the CONSERVATION OF ENERGY (q. v.) and the Periodic Law. The one dealt with a small number of observations. Exactitude was the main thing. The hypothesis itself sprang almost immediately from the natural light of reason. In the other case, it was necessary with a positive effort to put ideas of exactitude aside and to find order in a great tangle of facts.

Perhaps the problem in hand relates to one of those sciences basely called descriptive, that is, sciences which study, not classes of facts, but individual facts, such as history, descriptive astronomy, geography. No science is merely descriptive. These sciences are investigations of causes. The historian's facts of observation are not those contained in his text, but those mentioned in the foot-notes—the documents and monuments. It is the supposed causes of these which make the text. Nor is he contented with a mere chronicle of striking public events; he endeavours to show what the hidden causes of them were. So the astronomer's real business is to prove the NEBULAR HYPOTHESIS (q. v.) or whatever ought to replace it. The geologist does not merely make a geological map, but shows how the existing state of things must have come to pass. To do this the historian has to be a profound psychologist, the geologist a master of physics and dynamics. Just as the classificatory sciences tend to become nomological, so the descriptive, or explanatory, sciences tend to become classificatory. The astronomer finds so many examples of systems in formation, that he can formulate the cycle of events through which they generally pass; as the historian formulates cycles through which communities usually pass, and the geologist formulates cycles through which continents commonly pass. These are analogous to the cyclical laws of the classificatory sciences.

But perhaps the problem before the student is not one of theoretical physics or of theoretical psychics, but a practical problem. He wishes to invent. In that case he ought to have a great knowledge both of facts about men's minds and of facts about matter; for

he has to adapt the one to the other. He ought to know more than any pure scientist can be expected to know. Of course, as the world goes, he does not.

(2) The most vital factors in the method of modern science have not been the following of this or that logical prescription—although these have had their value too—but they have been the moral factors. First of these has been the genuine love of truth and conviction that nothing else could long endure. Given that men strive after the truth, and, in the nature of things, they will get it in a measure. The greatest difference between the scientific state of the modern scientific era from Copernicus and the middle ages, is that now the whole concern of students is to find out the truth; while then it was to put into a rational light the faith of which they were already possessed. The chief obstacle to the advance of science among students of science in the modern era has been that they were teachers, and feared the effect of this or that theory. But the salvation from this danger has been the fact that there was no vast institution which anybody for a moment hoped could withstand the mighty tide of fact. The next most vital factor of the method of modern science is that it has been made social. On the one hand, what a scientific man recognizes as a fact of science must be something open to anybody to observe, provided he fulfils the necessary conditions, external and internal. As long as only one man has been able to see a marking upon the planet Venus, it is not an established fact. Ghost stories and all that cannot become the subject of genuine science until they can in some way be welded to ordinary experience. On the other hand, the method of modern science is social in respect to the solidarity of its efforts. The scientific world is like a colony of insects, in that the individual strives to produce that which he himself cannot hope to enjoy. One generation collects premises in order that a distant generation may discover what they mean. When a problem comes before the scientific world, a hundred men immediately set all their energies to work upon it. One contributes this, another that. Another company, standing upon the shoulders of the first, strike a little higher, until at last the parapet is attained. Still another moral factor of the method of science, perhaps even more vital than the last, is the self-confidence of it. In order to appreciate this, it is to be remembered that the entire fabric of science has to

be built up out of surmises at truth. All that experiment can do is to tell us when we have surmised wrong. The right surmise is left for us to produce. The ancient world under these circumstances, with the exception of a few men born out of their time, looked upon physics as something about which only vague surmises could be made, and upon which close study would be thrown away. So, venturing nothing, they naturally could gain nothing. But modern science has never faltered in its confidence that it would ultimately find out the truth concerning any question in which it could apply the check of experiment.

These are some of the more vital factors of the method of modern science. For the purely logical elements the reader should consult special topics, e.g. REASONING, PROBABLE INFERENCE, PSYCHOPHYSICAL METHODS, ERRORS OF OBSERVATION, EMPIRICAL LOGIC, VARIATION, &c. (C.S.P., J.M.B.)

Sclerosis [Gr. σκληρός, hard]: Ger. *Sklerose*; Fr. *sclérose*; Ital. *sclerosi*. Induration of the substance of the central nervous tissue, usually by the increase of fibrillary connective tissue.

The medullary sheaths are destroyed, but the axis cylinder often persists for a long time thereafter. The blood-vessels show an increase in their nuclei and a thickening of the walls.

Multiple sclerosis: a diffuse sclerosis where foci of hardening are scattered throughout the central nervous system, especially in the white matter. The cause of the disease is obscure, and its symptoms vary by reason of the diverse sites of the lesions.

Amyotrophic (myoatrophic) lateral sclerosis: an affection of the cortico-muscular tract of the cord, appearing as a degenerative atrophy in the lumbar region. Atrophy of the muscles soon supervenes. The hardening of the interstitial tissue goes hand in hand with the swelling of the axis cylinders and atrophy of the motor neurones. The cause of the disease is unknown.

Primary lateral sclerosis (spastic spinal paralysis): this disease is characterized by exaggerated tendon reflexes and paralysis of the limbs.

Combined lateral and dorsal (posterior) sclerosis resembles TABES (q. v.). (H.H.)

Scope (in logic): Ger. *Umfang*; Fr. *étendue, portée*; Ital. *estensione*. The aggregate of subjects to which a term, proposition, reasoning, inquiry, treatise, &c., refers or is intended to refer; the logical *breadth*. Cf. EXTENSION (in logic).

Whether it embraces real individual things external to the mind, or individual percepts, or general terms, is a question upon which there is no agreement among logicians. We may accept the statement of B. Erdmann that the aggregate of species constitutes the scope (Umfang) in the proper sense of the term, while in a broader sense it comprises the collection of single objects. (C.S.P.)

Scotism: Ger. *Scotismus*; Fr. *Scotisme*; Ital. *Scotismo*. The philosophic system and tendencies of Joannes Duns Scotus; opposed to Thomism, the system of St. THOMAS (q. v., philosophy of). It is characterized by its tendency to separate philosophy from theology (see TWOFOLD TRUTH); its indeterminism, and emphasis upon will (see VOLUNTARISM); and by a movement in the direction of nominalism, although Scotus himself remained a realist. See TERMINISM, OCCAMISM, and REALISM (1). (J.D.)

Scottish Philosophy: see NATURAL REALISM, and REALISM.

Scotus Erigena: see ERIGENA, SCOTUS, and SCHOLASTICISM, I.

Scotus, Joannes Duns: see DUNS SCOTUS, JOANNES, and SCHOLASTICISM, II.

Scriptures [Lat. *scripturae*, from *scribere*, to write]: Ger. *heilige Schrift*; Fr. *Écritures*; Ital. *Sacre Scritture*. The sacred writings or books of any religion containing inspired and authoritative enunciations regarding doctrine, worship, or the conduct of life. In particular, the sacred writings of Judaism and Christianity as contained in the BIBLE (q. v.).

Literature: see BIBLE, and KORAN. (A.T.O.)

Scruple [Lat. *scrupulus*, a small sharp stone]: Ger. *Skrupel*; Fr. *scrupule*; Ital. *scrupolo*. Less important ground of moral hesitation; applied also to moral hesitation without ground. (J.M.B.)

Secondary (or -darily) Automatic: see AUTOMATIC ACTION.

Secondary Quality: see QUALITY AND QUALE.

Secrétan, Charles. (1818-95.) Educated at Lausanne, and studied at Munich under Schelling. After some years as lawyer and editor of the *Revue Suisse*, he became professor of philosophy at Lausanne (1841), Neuchâtel (1850), and Lausanne again (1866). Besides his work in general philosophy, he was a strong factor in French Protestant theology, and took a prominent part in the social movements of Latin Switzerland.

Secretion [Lat. *secretio*, a dividing]: Ger.

Absonderung; Fr. *sécrétion*; Ital. *secrezione*.

(1) The elaboration and separation of substances by glandular cells. See GLAND.

(2) Substance thus elaborated or separated.

The term was early applied to the original conception, viz. that a gland simply separated out different constituents already existing in the blood and lymph. More careful analysis soon demonstrated that the characteristic substances of many secretions were not present in the blood, hence, more and more importance has come to attach to the work of secreting cells in transforming and elaborating their special products. The secreting cells must be supposed to have the power of causing their secretions to flow in a definite direction, generally towards the duct of the gland or towards a free surface, while other products of their activity are turned back towards the basement membrane and enter the lymph and blood stream. The entire secretion of certain ductless glands, such as the glandular portion of the pituitary body, thymus, and adrenal body, as well as an important part of the secretions of other glands, come into this relation with the blood. These are called internal secretions. Substances secreted that are of use to the body are sometimes designated as true secretions; while those that are injurious and must be removed from the body are termed excretions. (C.F.H.)

The importance of certain of the internal secretions has recently been shown both in the economy of organic life and growth and as of developmental significance; especially in two ways: (1) as being necessary to the health and normal function of organs seemingly very remote, and (2) as showing utility in organs having apparent function. (J.M.B.)

Sect [Lat. *secta*, from *secare*, to cut]: Ger. *Religionspartei*, *Sekte*; Fr. *secte*; Ital. *setta*. A body within a larger organization, whose members are bound together, and to a greater or less degree differentiated from the remaining members, by certain distinctive doctrines or practices.

A sect may exist without organization or it may organize and reach the stage of a schism. The Reformation created a schism in the Romish Church, and many of the sects of Protestantism have led to schisms.

The topic and the term have become important in recent sociological discussion (cf. Simmel, 'The Persistence of Social Groups,' *Année Sociol.*, i); see (for literature) SOCIOLOGY, and SOCIAL PSYCHOLOGY, and cf. GROUP (social). (A.T.O.)

Secundum quid [Lat.]: relatively; under limitations in certain respects. See PERSEITY, *passim*. (C.S.P.)

Segmentation [Lat. *segmentum*, a segment]: Ger. *Segmentation* (cf. CLEAVAGE); Fr. *segmentation*; Ital. *segmentazione*. (1) The division of the developing ovum into several cells. See CLEAVAGE.

(2) The division of the body of an animal into a series of segments, or metameres, of more or less similar structure.

Amongst animals, especially those of elongated shape, there is almost always a tendency, so to speak, towards a reduplication of parts, which may lead to the formation of a series of very similar segments, as in worms and arthropods. Segmentation usually takes its origin in the mid-layer, mesoderm, the coelom being formed as a series of cavities in the embryo. In higher forms this metameric segmentation may again become obscured by the fusion and modification of a number of segments, as for instance in the formation of the vertebrate head. See EMBRYOLOGY, and COELOM.

(C.L.L.M.—E.S.G.)

Segregation: see ISOLATION.

Selection (in biology) [Lat. *selectus*, chosen]: Ger. (1) *Auswahl*, (2) *Auslese*, *Selektion*; Fr. *sélection*; Ital. *selezione*, *scelta*. The process by which preferential survival is effected in the struggle for EXISTENCE (q. v.).

Selection in this sense may be (a) conscious and purposive, i. e. with the improvement of the race as a definite end in view, e. g. man's selection in many of its phases; (b) conscious but not purposive, e. g. sexual selection (selective mating) among animals; or (c) unconscious, as in natural selection, when, for example, hardy birds survive through a severe winter.

Thus (cf. SELECTION, in psychology):

(1) Conscious selection—

(a) Purposive (artificial, social).

(b) Non-purposive, e. g. sexual.

(2) Unconscious selection (natural selection).

Under unconscious selection we have:

(a) *Purposive selection*. Darwin used the phrase ARTIFICIAL SELECTION (q. v.) for the purposive improvement by man of animals or plants by breeding. One of two broadly contrasted methods may be employed in accordance with circumstances: (1) the best animals or plants may be chosen out for the propagation of the race; (2) the weakly, or those which depart in some way from the desired type, may be eliminated or excluded from such propagation. The net result, so

SELECTION

far as the continuance of the race is concerned, is much the same in either case; but the method by which it is reached differs according as we begin with the best (chosen for propagation) and work downwards, or begin with the worst (chosen for destruction) and work upwards.

We may use the phrase **SOCIAL SELECTION** (q. v., Baldwin) for purposive selection in and by mankind under social conditions. Here the reference to the improvement of the race and the propagation of the best is largely indirect; but the selection is in conformity with some ideal. And by choosing out the best, morally and intellectually, for positions of trust and emolument, and by hanging or imprisoning the worst—'social suppression'—an influence on the race of the future is produced.

(b) *Non-purposive selection.* This closely corresponds with James Ward's **SUBJECTIVE SELECTION** (see *Encyc. Brit.*, 9th ed., art. Psychology). Here the effects are wrought through an appeal to the consciousness of the organism—though there is no purposive end in view beyond, at most, immediate gratification. Darwin used the phrase **SEXUAL SELECTION** (q. v.) to include (1) selective mating, (2) elimination through combat at the sexual period. The two are no doubt closely connected; but the appeal to consciousness is more direct in the former. In selective mating, that individual is chosen as mate which most strongly stirs the sexual impulse. Selection is from above downwards. In the contests of males the weakest are killed or maimed. Elimination is from below upwards. Apart from sexual selection, consciousness plays its part in the struggle for existence among all the higher animals, though its effects are difficult to disentangle from those of unconscious selection. Where animals, for example, prey upon each other, consciousness as a factor cannot be excluded.

(c) *Unconscious selection.* In very much of what Darwin termed **NATURAL SELECTION** (q. v.), consciousness plays no part throughout the vegetable kingdom, for example. Here the method is entirely that of elimination from below upwards. The weakest go first; only the ultimate survivors reach maturity and mate. In what Weismann has termed *personelle Selektion* (in English individual selection), individuals survive in virtue of the possession of adaptations sufficiently marked to enable them to escape elimination. In **GROUP SELECTION** (q. v.) survival is largely

determined not by individual adaptation *per se*, but by the co-ordinated relationships within the group. The survival of certain groups of insects, for example, may have been determined by the production of imperfect females or neuters, and by the division of labour thus rendered possible. In what Karl Pearson has termed **REPRODUCTIVE OR GENETIC SELECTION** (q. v.), when the variation of an organ or character is correlated with greater fertility, there is under heredity a *vera causa* of progressive evolution of this organ or character; since an increasing number of individuals will be born with the organ in excess (or defect), and consequently the mean of the general population will be progressively modified. The term **INTRASELECTION** (q. v., Roux) has been applied to the results of a competition between the cells, tissues, or organs for the necessary nutriment in the 'struggle of parts.' It would seem to be a factor in the modifications of individual life rather than in the genesis of hereditary variations. Weismann has suggested that there is a similar process in the germinal substance (**GERMINAL SELECTION**, q. v.) whereby the 'determinants' of certain characters absorb nutriment more rapidly or effectually than those of other characters, and thus produce stronger descendants. Mark Baldwin has suggested that the phrase **ORGANIC SELECTION** (q. v.), or indirect selection, be applied to the process by which **COINCIDENT VARIATIONS** (q. v., Ll. Morgan) are favoured and nursed in individuals which survive through accommodation to the environment, reached by tissue modifications. Romanes applied the phrase **PHYSIOLOGICAL SELECTION** (q. v.) to the race survival of those organisms which are sexually compatible, or of those intergenerants whose sexual products ripen at the same period, the sexually incompatible and those intergenerants whose sexual products ripen at different times being eliminated from race-propagation.

Mark Baldwin employs the term **FUNCTIONAL SELECTION** (q. v.) to the conscious selection by the individual through a process of trial and error of those movements by which satisfactory results are attained (cf. **EXPERIMENTATION**, as a mental process). This, like intraselection, is a factor in the modification of individual life, but through 'organic selection' may take effect in the race.

The phrase 'selective agents' is applied to those environmental forces or groups of forces through which selection in any of its

SELECTION

phases is effected. Romanes suggested that the term 'selection value' be applied to that amount of utility which suffices to determine survival. It is beginning to be recognized that the statistical method must be rigorously applied so as to enable biologists to formulate in definite numerical terms the results of selective processes. (C.L.L.M.)

The following table, first printed by the writer in *Science* (Nov. 19, 1897), and revised to include suggestions made by Osborn, Poulton, and L. Morgan, classifies the different sorts of selection in a way to distinguish the means in each case from the result. The phrase 'utility selection' is current for

as cited; GROOS, *The Play of Animals* (Eng. trans.), and *The Play of Man* (Eng. trans.); MORSELLI, *Antropol. gen.*; GROSSE, *Selezione fen. psych.*; the topics referred to. (C.L.L.M.)

Selection (method of): see **MEMORY** (experiments on).

Selection (in psychology; and **Selective Synthesis**): Ger. *Wahlvorgang* (selective process); Fr. *sélection*; Ital. *selezione*. The principle of selection is that out of all the manifold changes of sensory presentation which a given individual experiences, only a few are so related to pre-existing subjective tendencies as to secure lodgment in consciousness.

SORT.	MEANS.	RESULT.
1, 2. Natural Selection.	{ 1. Struggle for Existence. 2. Inherent Weakness; without Struggle.	{ 1. 'Survival of the Fittest' Individuals. 2. Destruction of Unfit Individuals.
3. Germinal Selection.	3. Struggle of Germinal Elements.	3. Survival of Fittest Germinal Elements.
4. Intrasélection.	4. Struggle of Parts.	4. Survival of Fittest Organs.
5. Functional Selection.	5. Overproduction of Movements.	5. Survival of Fittest Functions.
6. Organic Selection.	6. Accommodation, Individual Adaptation, Modification.	6. Survival of Accommodating Individuals.
7. Artificial Selection.	7. Choice for Planting and for Mating together.	7. Reproduction of Desirable Individuals.
8. Personal Selection.	8. Choice.	8. Employment and Survival of Socially Available Individuals.
9. Sexual Selection.	9. Conscious Selection by Courting, &c.	9. Reproduction of Attractive Individuals.

LLOYD MORGAN, *Animal Life and Intelligence*; *Habit and Instinct*; and *Animal Behaviour*; A. WEISMANN, *Germinal Selection*; K. PEARSON, *Chances of Death*; and *Grammar of Sci.* (2nd ed., 1900); J. WARD,

The objects which are thus selected must be such as can be connected with each other in the mind of the subject. This connection is called 'selective synthesis.' Hence selection in general involves selective synthesis, which is also variously called 'selective thinking,' 'mental determination,' &c.

The terrier pays no attention to a daisy, but it is keenly aware of the presence of a rat, and of all that belongs to the pursuit and killing of a rat. The timber merchant as such and the artist as such do not perceive the same features in a wooded landscape. In general, the world as it appears to the

individual subject is relative to his interest. Only those items in it which appeal to his interest are discriminated and related.

(G.F.S.—J.M.B.)

Theories of selection are: (1) that there is immediate fusion or union between new and old elements of experience by immanent laws of 'assimilation,' 'association,' &c., such as resemblance, non-contradiction; (2) that there is actual testing of all new items of experience, those being selected which are found to work; (3) that there is SYNERGY (q. v.) of motor processes which precedes and explains the assimilation of sensory content; (4) that there is a mass of dispositional tendencies—attention, interest, &c.—to which new items must in some way conform. These theories are not mutually exclusive; indeed, the last three are readily united into one—the motor or synergy theory—as against the first, which is the sensory or presentation theory. Cf. SELECTION (in biology), SELECTIVE THINKING, and RELATIVE SUGGESTION, and cf. PRAGMATISM.

In the higher grades of mind the attention is the selecting function, but in lower forms we still find objective signs of selection. So evident is this that it is currently held (Romanes, *Ment. Evolution*; Ll. Morgan, *Habit and Instinct*; Baldwin, *Ment. Devel. in the Child and the Race*) that this is the best criterion or test of the presence or consciousness in an organism—its 'selective' response to stimulation.

The principle of selective synthesis, or synthesis under the leading of selection, has been used to disprove associationism (James, Ward); it has also been invoked as evidence of a purely mental 'activity,' and again, of a mental substance or soul, of which this is the function of self-activity. Further, under the term SUBJECTIVE SELECTION (q. v., and cf. ORGANIC SELECTION), it has been made a philosophical principle (Ward, *Naturalism and Agnosticism*) and applied as well to the function of the organism in selecting its living environment, and so securing its own survival. The same process, looked at from an objective point of view, is termed 'conscious,' as opposed to 'unconscious' SELECTION (q. v., in biology).

(J.M.B., G.F.S.)

Selection (social): see SELECTION, and SOCIAL SELECTION.

Selection (or **Selective**) **Value**: see UTILITY (in biology), and cf. SELECTION (in biology).

Selective Agents: see SELECTION (in biology).

Selective Synthesis: see SELECTION (in psychology).

Selective Thinking: Ger. (*das*) *auslesende Denken*; Fr. (*la*) *pensée sélective*; Ital. (*il*) *pensiero selettivo*. Used by the present writer (*Social and Eth. Interpret.*, and 'Pres. Address,' in *Development and Evolution*), for the 'systematic' or progressive and continuous determination of the stream of thought in the individual's mind.

For theories see SELECTION (in psychology), and PRAGMATISM, which latter includes the theory of selective thinking by the criterion of 'workability' or utility of the elements selected.

Literature: SIMMEL, Arch. f. system. Philos., i. 34; DEWEY, The Significance of the Problem of Knowledge, in Univ. of Chicago Contrib. to Philos., i; and Ped. Sem., v. 3 (Jan. 1898); BALDWIN, as cited; URBAN, Psychol. Rev., July, 1897, vi. 361. (J.M.B.)

Self [Lat. *se*]: Ger. *Selbst*; Fr. (1) *soi-même*, (2) *le moi*; Ital. (1) *l'io*, (2) *il me*. (1) The subject of the individual's consciousness or self-consciousness, and (2) the object of the individual's self-consciousness.

'That subject whose activity is the subject's object' (Volkman, *Lehrb. d. Psychol.*, 4th ed., ii. 217).

Considered simply as subject of experience, whether simply the system of experience itself (Stout) or that to which experience is presented, the self is called the unreflective or primary self as opposed to the subject-self of self-consciousness.

In reflective consciousness the self is not only subject—the subject-self—but it is also object of its own reflection—object-self. The object-self, however, when thus made object, is at the same time identified with the subject-self, which is said to reflect. This peculiar fact, that the subject that reflects is at once also its own object of reflection, is the great mystery of philosophy and the basis of systems of speculative thought. Lotze sees in the fact of self-consciousness a case of identity in change which fulfils the demands of philosophy for an explaining principle of the world order. Kant and Herbart distinguished clearly the so-called empirical and rational selves, and based upon the distinction that between the noumenal or

real and the phenomenal ego. Recent analyses have held that the self-content is complex, and that the subject-self is in some way a fuller statement of the elements which at the same time go to make up the lesser content presented as the object-self (Bradley), or that the subject-self is an active attitude or tendency reacting upon the partial content of self which at the time arouses it (Baldwin). Herbart (*Lehrb. d. Psychol.*) has a classical analysis of the nature and growth of the concept of self. Other important statements are by James Mill and James Ward.

Apart from the interpretation of reflective self-consciousness, the empirical or object-self—called by James the ‘me’—as opposed to the rational or subject-self—called the ‘I’—has had full treatment by the psychologists, both as to its elements and to its genesis. Contemporary psychology has accepted the fact that the self-content is complex. The assertion of an absolutely simple and undecomposable self, revealed by intuition and made the object of knowledge, is now seldom heard, and when it is heard it is usually based upon a failure to distinguish between the ‘me’ and the ‘I’; or, if not that, the reference is to the continuous subject which, by the terms of the distinction, can only be analysed by first converting it into an object, and thereby setting up another subject—which again defeats analysis.

Recently much has been made of the social factor in the development of the concept of self (especially by Royce and the present writers). It has been shown that the self-thought grows by imitation and suggestion, being gradually built up under the stimulus of the social life correlatively with the notion of the personal other-self or ‘alter.’ Cf. EGO, ALTER, SOCIUS, EJECTION, and INTROJECTION.

Literature: the histories of philosophy (their treatment of Descartes), and the great philosophers, notably KANT, BERKELEY, FICHTE; HERBART, *Metaphysik*, ‘*Ontologie*’; HUME, *Treat. on Human Nature*, Pt. IV; LOTZE, *Metaphysics*, Bk. I. chap. vii, and Bk. III. chap. i. On the psychology: JAMES, *Princ. of Psychol.*, i. chap. x; ROYCE, *Spirit of Mod. Philos.*; and *Stud. in Good and Evil*; ARDIGÒ, *L’unità della Coscienza*, Op. *Filosofiche*, vii (1898); BRADLEY, *Appearance and Reality*, chaps. ix, x; STOUT, *Manual of Psychol.*; BALDWIN, *Social and Eth. Interpret.*; MEZES, *Ethics Descrip. and Explan.*, chap. vii. For disturbances of self-consciousness, see PERSONALITY (disorders of). (J.M.B.—G.F.S.)

Self (feeling or emotion of): Ger. *Selbstgefühl*; Fr. *sentiment du moi*, *sentiment égoïste ou personnel* (see Ribot, *Psychol. des Sentiments*, 236—TH.F.); Ital. *sentimento di sè*. Feeling excited by the thought of self. Cf. HUMILITY, PRIDE, and SHAME. (J.M.B.)

Self (pathology of, alterations of, perversions of, &c.): see PERSONALITY (disorders of).

Self-activity: Ger. *Selbstthätigkeit*; Fr. *propre activité*; Ital. *attività propria* (or *autonomia*). (1) Change determined within a being without other conditioning factors, and without destroying the identity of the being; entirely immanent change.

(2) Such change within the psychic self.

The conception of self-activity is subject to all the embarrassments of those of cause and change. The term *causa sui* is the older way of designating it in its application to any sort of reality.

As used in current thought it is applied mainly to the mental self (2), and varies from pure accidentalism to a theory of relative SPONTANEITY (q. v.) in its interpretation of the activity involved, and from pure transcendentalism to sensational empiricism in its interpretation of the self involved. The definition given is the least that the term can mean; it leaves open the further questions as to what besides change activity may mean, and what besides an immanent principle of organization the psychic self may mean. Those who cannot allow even this may argue that there is no self-activity.

The identity of the self having the activity must be preserved in a case of self-activity. Yet it may well be a point of subtle discussion whether a self-active being can commit suicide. We might say in regard to the matter of predication that it is made on the strength of earlier exercises of this activity; but they would be cases, indeed, in which the being remained after the activity. We might say such an activity may be a development which spends itself, reaching an end-state at which it stops; but that would mean that such a development must have started; and how could self-activity start? Its first action would be due to something not itself; and if the first act was not self-activity, neither would the second be in which the first issued, nor the third, &c.

Furthermore, it is difficult to see what a psychic principle of self-activity could be. It could not be knowledge, since knowledge is in some degree conditioned upon its object;

nor volition, since volition involves ends which are, as knowledge, also objects; nor feeling, since feeling seems most of all under organic conditions. Probably a self-active mind could only be an absolute mind; and with it the question of its mode of self-determination would be open for discussion.

Literature: LOTZE, *Metaphysics*; HARRIS, *The Logic of Hegel*, and *Psychol. Foundations of Education*; ORMOND, *Basal Concepts in Philos.*; HOWISON, in *Royce's Conception of God*. (J.M.B.)

Self-consciousness: Ger. *Selbstbewusstsein*; Fr. *conscience de soi-même*; Ital. *coscienza di sè*. (1) The process or state of reflection on the self. See SELF, PERSONALITY (disorders of), and REFLECTION.

(2) Used popularly for the 'nervousness' or 'flurry' which comes from directing attention to one's own person or performances.

In this sense it is a manifestation of SHYNESS (q. v.). (J.M.B., G.F.S.)

Self-control: Ger. *Selbstbeherrschung*; Fr. *maîtrise de soi-même*; Ital. *dominio di sè stesso*. CONTROL (q. v.) exercised in social and moral relationships; it concerns not only the efficiency of volitions when formed, but also the process of forming them.

The volitions of the man who possesses self-control flow from full deliberation and express personal character as a unified system. Absence of self-control is marked by volitions flowing from detached and momentary impulses. (G.F.S.—J.M.B.)

Self-denial or Self-sacrifice: Ger. *Selbstverleugnung*; Fr. *sacrifice de soi-même*; Ital. *abnegazione, sacrificio di sè*. Voluntary relinquishment of something desirable which is within one's reach or which is thought to be one's right.

This is a fundamental conception of Christian ethics. It has two great illustrations: (1) the sacrifice of the lower to the higher self; (2) the sacrifice of self for others. In the former aspect it has sometimes been so exaggerated (by the Cynics and Stoics, and in mediaeval monasticism) as to make morality largely negative. Cf. ASCETICISM. On the other hand, the idea of SELF-REALIZATION (q. v.) gives a positive interpretation of self-sacrifice. In its second aspect, self-sacrifice is the presupposition of a genuine altruism or disinterested service of others, and in this sense it must be regarded as a distinctive and original principle of Christian ethics. Even here, however, as Mill points out (*Utilitarianism*, chap. ii), self-sacrifice is a means rather than

an end-in-itself. Cf. Lecky, *Hist. of European Mor.*, chap. iv. (J.S.)

Self-determination: Ger. *Selbstbestimmung*; Fr. *détermination par soi-même*; Ital. *determinazione per sè (or interna)*. The determination of volition by psychic elements alone.

Held by the theory of 'inner determinism,' which opposes the view of 'external determinism,' that elements of an extra-psychic kind enter into voluntary action. It holds that volition is always conditioned upon motives, dispositions, and other psychic events only, thus being opposed on the other side to INDETERMINISM or ACCIDENTALISM. See these terms, and WILL (also for literature). (J.M.B.)

Self-estrangement: Ger. *Selbstvergessenheit, Vertiefung*; Fr. (not in use); Ital. (*lo straniarsi*). The process of sinking the mind in what is foreign or alien to its customary habit of thought, in order the more fully to absorb and assimilate the new experience.

Self-estrangement and its removal is the twofold process of culture. The commonplace soon fails as a stimulus to growth; the novel, the wonderful, the strange is demanded. As soon as any one of these appears, consciousness departs from its customary mode of activity, and sinks itself in contemplation of the new experience. The self is, in other words, estranged from its ordinary course of thought, only in the end to return to its normal state enriched by the treasures it has seized in its momentary departure from habitual modes of thinking. The estrangement may be the matter of an hour, a day, a year, or a college course. It has been held that the greater the self-estrangement and the longer its continuance, provided it is in the end fully overcome, the greater the culture. Thus a college student may spend years in the study of ancient languages and systems of thought, and yet be the stronger thereby, provided he fully assimilates what he learns, and is able to see its significance in modern life. Herbart appears to limit the process to the absorption and the reflection that are involved in actual instruction from day to day. See ABSORPTION, and REFLECTION (in education).

Literature: ROSENKRANZ, *Philos. of Educ.*, 27; HARRIS, *Psychol. Foundations of Educ.*, 240-7; HERBART, *Sci. of Educ.* (trans. by Felkin), 123. (C.D.E.G.)

Self-evident: see EVIDENCE AND EVIDENT, Self-evidence under TESTS OF TRUTH,

and CLEAR AND DISTINCT; and cf. IMMEDIATE AND MEDIATE (3).

Self-exhibition: Ger. *Selbstdarstellung*; Fr. *parade, étalage de soi*; Ital. (*fare*) *mostrare di sé, pompeggiarsi* (vb.). The display of one's own qualities or capacities before spectators, or as if before them.

Self-exhibition has been recognized in recent literature as a natural impulse, both spontaneous and reflective. In its spontaneous form it has been connected with the display of the animals—notably for sexual attraction, e.g. the male among birds (cf. SEXUAL SELECTION)—and with native bashfulness and COYNESS (q.v.) in the opposite sex (see also TIMIDITY).

Its value in the social life is very great, since it brings the characters of the individual to the attention of his fellows, and thus secures social recognition and response. In its higher forms—in which the actual audience is no longer necessary, but the self-exhibition is 'as if' before spectators—it has been considered one of the fundamental elements of the art-impulse (see ART AND ART THEORIES).

It would be well to designate the purely impulsive and instinctive forms of self-exhibition associated with mating by the term 'display,' which is already in use by the biologists (cf. RECOGNITION MARKS); reserving 'self-exhibition' for cases in which there is a more or less developed consciousness of self. The English term was suggested by the present writer (*Psychol. Rev.*, 1, Nov. 1894, 620).

Literature: MARSHALL, Pain, Pleasure, and Aesthetics; and Aesthetic Principles; GROOS, Play of Animals, and Play of Man (Eng. trans. of each); HIRN, The Origins of Art, chap. xiv; BALDWIN, Social and Eth. Interpret.; the literature of SEXUAL SELECTION (notably DARWIN and WALLACE). (J.M.B.)

Self-interest: Ger. *Eigennutz*; Fr. *intérêt personnel*; Ital. *interesse proprio*. That which is conceived to be in some respect advantageous for self. Cf. INTEREST (2). (J.M.B.)

Selfishness: Ger. *Selbstsucht*; Fr. *égoïsme*; Ital. *egoismo*. Regard for one's own interests to a degree which prevents full recognition of the interests of others. Cf. SELF-INTEREST.

(J.S.—J.M.B.)

As contrasted with egoism, selfishness relates to the practical evident utilities or gains accruing to the self through action. A man may be an egoist from absorption in self and in exclusive interests, to whom the term selfishness would not commonly be applied.

The reference to others is either positive or negative. Selfishness may show itself either in actual conduct or only in the omission of something which bears upon the interests of others. (J.M.B.)

Butler distinguishes 'cool or settled selfishness' from 'passionate or sensual selfishness.' His usual term for the former is SELF-LOVE (q.v.). 'But the most natural way of speaking plainly is to call the first only, self-love, and the actions proceeding from it, interested: and to say of the latter, that they are not love to ourselves, but movements towards somewhat external: honour, power, the harm or good of another; and that the pursuit of these external objects, so far as it proceeds from these movements (for it may proceed from self-love), is no otherwise interested than as every action of every creature must from the nature of the thing be: for no one can act but from a desire, or choice, or preference of his own' (Pref. to *Sermons*, § 29). For literature see SELF-LOVE. (J.S.)

Self-knowledge: Ger. *Selbsterkenntniss*; Fr. *connaissance de soi*; Ital. *conoscenza di sé*. Loosely used—as in the γνῶθι σεαυτόν of the oracle—for a more or less adequate apprehension of one's own capabilities. No technical use of the term is recommended. (J.M.B.)

Self-love: Ger. *Selbstliebe, Eigenliebe*; Fr. (*l'*) *amour de soi, égoïsme*; Ital. (1) *amor di sé*, (2) *amor proprio*. (1) The impulses to SELF-PRESERVATION (q.v.).

(2) Disposition to pursue the interests of self; the motive to EGOISM (q.v.).

In the first sense the term covers both the organic and the mental attitudes of an impulsive sort, prompting to self-preservation, called variously 'love of life,' impulse to 'self-defence,' 'conatus' (Spinoza), &c. It is only in the latter of the two senses given that self-love is a matter of ethical or religious sanction, although the distinction has not always been made in the history. (J.M.B.)

(2) Self-love is a sentiment having for its object the good of the self as distinguished from the good of others, leading to action intended to promote this good or to defend it, and to various emotions which are pleasurable in so far as the private advantage of the self is believed to be advanced, and unpleasant in the reverse case. (G.F.S.)

The Christian principle of self-sacrifice has often been so interpreted as to negate and condemn the principle of self-love or self-interest, as its opposite, and the root of all moral evil. The leading Christian moralists,

however, have distinguished between excessive and legitimate self-love, as Thomas Aquinas, who says: 'Every act of sin proceeds from an inordinate craving after some temporal good. This, again, proceeds from an inordinate love of self; for to love any one is to wish him good. Therefore inordinate love of self is the cause of all sin.' He quotes St. Augustine's saying that 'self-love, reaching to contempt of God, makes the city of Babylon' (*Summa*, I. ii. Q. 77, art. 4, Eng. trans. by Rickaby; *Aquinas Ethicus*, 240-1). On the other hand, 'There is a well-ordered self-love, due and natural, whereby a man wishes for himself the good that befits him; but the love that is set down as a cause of sin is an inordinate self-love, leading to a contempt of God' (loc. cit.). 'A man ought to love himself, after God, more than any other person' (ibid. II. ii. Q. 26, art. 4). It is only the good who can thus truly love themselves, for they alone truly know themselves, i.e. as rational beings, and they alone are worthy of love, i.e. as good, or partakers in the divine goodness (ibid. II. ii. § 25, art. 7). This true self-love, so far from contradicting the love of others, is its presupposition. 'As unity is the principle of union, so the love wherewith one loves oneself is the form and root of friendship: for our friendship for others consists in bearing them that regard which we bear ourselves' (ibid. II. ii. Q. 25, art. 4).

Butler similarly distinguishes rational, or reflective, from passionate self-love. Regard for our own interest or happiness is a no less rational principle of action, he holds, than regard for the interest or happiness of others (benevolence). Both principles are approved by conscience, since both are, like conscience itself, reflective principles. Butler also insists strongly upon the harmony of self-love and benevolence as moral principles, and upon the suicidal character of a self-love which should exclude the disinterested love of objects and of other persons. The true self-love sees in the satisfaction of the particular 'propensions' the only means of its own fulfilment, the only possibility of happiness.

For Kant, self-love or self-interest is the radical principle of evil, summing up as it does that life of natural inclination which opposes the life of duty. 'All the inclinations together (which can be reduced to a tolerable system, in which case their satisfaction is called happiness) constitute self-regard (Solipsismus)' (*Critique of Pract. Reason*, chap. iii. 197; Abbott's trans., 165). In a different

and somewhat strained sense, Kant admits the possibility of a rational self-love. 'Pure practical reason only checks selfishness, looking on it as natural and active in us even prior to the moral law, so far as to limit it to the condition of agreement with this law, and then it is called rational self-love' (loc. cit.).

Spinoza defines self-love as 'the joy which arises from contemplating ourselves' (*Ethica*, Pt. III. Prop. 55, Schol.).

Literature: AQUINAS, SPINOZA, BUTLER, KANT, as cited; SPENCER, Data of Eth.; SIDGWICK, Pract. Eth.; PAULSEN, Syst. of Eth. (Eng. trans.), 179 ff., 244 ff.; WUNDT, Ethics, i; BALDWIN, Social and Eth. Interpret., 20, 266, 286. (J.S.)

Self-preservation (impulses of): Ger. *Selbsterhaltungstrieb*; Fr. *conservation personnelle*; Ital. *conservazione propria* (or *individuale*). The group of feelings and dispositions connected with the maintenance and development of life.

The term instinct, often used, is less exact than impulse, for reasons given under PLAY, which presents analogous conditions. Apparatus and tendencies for self-preservation are recognized both in biology and in genetic psychology as fundamental natural facts. In biology it appears in rejuvenation and regeneration, in defensive reflexes, in special instincts, &c.; in psychology, in various emotional conditions such as anger, revenge, and the corresponding active tendencies.

Important special constructions using this principle are those of Herbart ('Selbsterhaltung der Realen') and Avenarius (theory of the 'vital series' and its 'Erhaltung'). Vitalistic writers carry the principle over to the inorganic world (Paulsen), and philosophers bring under the general concept of conservation (Erhaltung, Conatus, Trieb) such different principles as heredity, conservation of energy, and inertia. (J.M.B.)

Self-preservation has been accepted as a fundamental ethical principle by Spinoza and Hobbes, while its importance is also recognized by Shaftesbury, Clarke, and Adam Smith. Spinoza sees in the *perseverare in esse suo* the universal *conatus* of existence, and finds in this principle the clue to virtue. 'Since reason demands nothing which is opposed to nature, it demands, therefore, that every person should love himself, should seek his own profit—what is truly profitable to him—should desire everything that really leads man to greater perfection, and absolutely that every one should endeavour, as far

as in him lies, to preserve his own being. . . . Again, since virtue means nothing but acting according to the laws of our own nature, and since no one endeavours to preserve his being except in accordance with the laws of his own nature, it follows that the foundation of virtue is that endeavour itself to preserve our own being, and that happiness consists in this—that a man can preserve his own being' (*Ethica*, Pt. IV. Prop. 18, Schol.).

Hobbes gives the principle an absolutely egoistic interpretation, and sees in it the fundamental 'natural right.' 'The right of nature, which writers commonly call *ius naturale*, is the liberty each man hath to use his own power, as he will himself, for the preservation of his own nature, that is to say, of his own life; and consequently of doing anything which, in his own judgment and reason, he shall conceive to be the aptest means thereunto' (*Leviathan*, Pt. I. chap. xiv). 'Every man, not only by right, but also by necessity of nature, is supposed to endeavour all he can to obtain that which is necessary for his conservation.' 'The final cause, end, or design of men who naturally love liberty and dominion over others, in the introduction of that restraint upon themselves, in which we see them live in commonwealths, is the foresight of their own preservation, and of a more contented life thereby' (*ibid.*, Pt. II. chap. xvii). All the 'laws of nature' are derived from 'the single dictate of reason advising us to look to the preservation and safeguard of ourselves.'

Shaftesbury distinguishes 'selfishness' or immoderate regard for private good, which is 'inconsistent with the interest of the species or public,' from such an 'affection towards private or self-good' as, 'however selfish it may be esteemed, is in reality not only consistent with public good, but in some measure contributing to it; if it be such, perhaps, as for the good of the species in general, every individual ought to share; 'tis so far from being ill, or blameable in any sense, that it must be acknowledged absolutely necessary to constitute a creature good. For if the want of such an affection as that towards self-preservation be injurious to the species, a creature is ill and unnatural as well through this defect as through the want of any other natural affection' (*Inquiry concerning Virtue*, Bk. I. Pt. II. § 2).

For Clarke, the principle represents the egoistic side of 'the rule of righteousness': 'With respect to ourselves, the rule of

righteousness is, that every man preserve his own being as long as he is able, and take care to keep himself at all times in such temper and disposition both of body and mind as may best fit and enable him to perform his duty in all other instances. . . . That every man ought to preserve his own being as long as he is able, is evident; because what he is not himself the author and giver of, he can never of himself have just power or authority to take away' (*On Natural Religion*, Prop. 1).

According to Adam Smith: 'Self-preservation and the propagation of the species are the great ends which nature seems to have proposed in the formation of all animals.' Accordingly, man is endowed not only with 'a desire of those ends and an aversion to the contrary,' but also with an instinctive apprehension of the means necessary to their attainment (*Theory of the Mor. Sent.*, Pt. II. § 1, chap. v, note).

Spencer regards self- and race-preservation as the ends of conduct, viewed from the standpoint of evolution (*Princ. of Eth.*, Pt. I. chap. ii). (J.S.)

Literature: besides the writers cited above, see WUNDT, *Logik*, ii. 258; HERBART, *Hauptpunkte d. Met.*, 42; AVENARIUS, *Krit. d. reinen Erfahrung*, i. 62 ff.; and the citations made under SELF-LOVE, and in EISLER, *Wörterb. d. philos. Begriffe*, 'Erhaltung.' (J.M.B.)

Self-realization: Ger. *Selbstverwirklichung*; Fr. *propre réalisation*; Ital. *svolgimento della propria personalità*. The fulfilment of the possibilities of development of the self. (J.M.B.)

The doctrine that the supreme end of conduct is self-realization or self-fulfilment is to be traced throughout the course of ancient and modern ethical thought. Its earliest and most important representative is Aristotle, for whom the good is the actualization of the human or rational soul. The Neo-Hegelians have brought the term 'self-realization' into prominence.

Literature: GREEN, *Prolegomena to Eth.*, Bk. III. chap. ii; DEWEY, *Outlines of Eth.*, Pt. I. chap. i; MACKENZIE, *Manual of Eth.*; MUIRHEAD, *Elements of Eth.* (J.S.)

Self-righteousness: Ger. *Selbstgerechtigkeit*; Fr. *propre justice*; Ital. *giustificazione di sé*. The attribution of RIGHTEOUSNESS (q. v.) to oneself.

Used in a derogatory sense, generally, for moral and religious pride. It is often made to include also an element of hypocrisy, as in the case of the Pharisee. (J.M.B.)

Semantics (or **Semasiology**) [Gr. *σημα*, a sign, + *λόγος*, discourse]: Ger. *Semantik*; Fr. *sémanitique*; Ital. *semantica*. The doctrine of historical word-meanings; the systematic discussion of the history and development of changes in the meanings of words. Cf. SIGNIFICATION, SIGNIFICS, and MEANING.

The value of a word at any time is determined solely by its power to convey meaning in a speech-community. What is called the etymology of a word serves only to help explain how a present meaning came to be what it is. Changes of meaning are in general brought about through the interplay of the normal and the occasional or special uses of a word. When the occasional entirely displaces the normal then the change is complete. Thus *head* once meant 'prayer'; it might also be applied to a ball of the rosary. This latter special meaning ultimately displaces the normal. The range of the occasional values of a word differs greatly with different individuals and in different communities. The commonly accepted range is a resultant of compromises dictated by the necessities of intelligibility, and constitutes the meaning of the word. Words empty or uncertain of meaning to the ears of one or more individual speakers may assume for them a meaning suggested by something in their forms or connections; thus *parboil*, whose prefix (*per-*) originally meant 'much,' 'very,' came through false suggestion of *part* to its present value. See PHONETICS, and cf. LANGUAGE.

(B.I.W.)

Locke (*Essay*, iv. chap. xxi. § 4) uses the term 'semiotic' (*σημειωτική*) in the somewhat broader sense of science of the use and meaning of words and signs in general. Further, the term 'semeiology' (also spelt 'semiology'), with 'semeiotic' (adj.), is used in medicine for the science of the signs or symptoms of disease.

(J.M.B.)

Literature: PAUL, *Principien der Sprachgeschichte* (4th ed., 1899); DARMESTETER, *The Life of Words* (1886); TRENCH, *Study of Words* (20th ed., 1888); BRÉAL, *Essai de Sémanitique* (Eng. trans., 1901); OERTEL, *The Scient. Study of Lang.*, 70 ff., 273 ff. (B.I.W.)

Semasiology: see SEMANTICS.

Semblance [Lat. *similis*, like, through Fr.]: Ger. *Schein* (and in compounds, *Schein-thätigkeit*, &c.); Fr. *semblant*; Ital. *sembianza*. A general term for those mental contents which simulate the real, but do not prove to be it.

Under this heading we have the class of facts

covered by the imaginative faculty when working under claim to cognitive validity, whether or not its claim be recognized as artificial and false by the subject. It has been called an 'inner imitation' of reality, in that it is—especially when its false claim is detected—a simulation of the marks of reality. This character is essential, and its nature appears more clearly in the cases distinguished below.

(1) The case of one extreme, 'conscious self-illusion' (*bewusste Selbsttäuschung*, K. Lange; *illusion volontaire*, Souriau); the indulgence in the temporary acceptance of a mental construction as real, with the knowledge, at the same time, that it is not. This is characteristic of much play and art enjoyment; one feature of which is that it throws the observer into a voluntary treatment of an artificial situation as real. Cf. SYMPATHY (aesthetic).

(2) The case of simple or actual ILLUSION (q.v.), in which the subject fails to detect the artificiality of the construction.

(3) The case of MAKE-BELIEVE (q.v., sense 1). In this, the construction has a social reference; the acceptance of it as real to another—an observer—is more or less clearly had in mind or intended, while the subject himself does not accept it as real. This distinction is important enough to be marked by a difference of terms; for while in the earlier cases—(1) and (2)—the acceptance of the construction by the subject carries with it usually also its validity to others as well—as notably in art—yet in them it is the self-illusion which constitutes the essential meaning of the experience.

(4) The other extreme case: feigning (cf. MAKE-BELIEVE, 3) without consciousness of causing illusion or misleading to another. This is the extreme or limiting case from the point of view of the mental life, because while it is semblance to the observer, it is not consciously so to the producer. Yet there is probably a colouring in consciousness corresponding to the quasi-social character of the state—as of lying in wait for, or of being gazed at by another—which is sufficient to allow its inclusion under the definition of semblance. The semblance here seems to be of biological utility, and to have arisen by natural selection.

The two extremes given in (1) and (4) represent an antithesis of points of view, as between psychology and biology, which is embarrassing in cases of other functions as well (e.g. imitation). What is

semblance to the observer may lack that character to the producer; this comes out notably in the cases of play and art (for note of it in the former case, see *PLAY*). Cf. Groos, *Play of Man* (Eng. trans.), Introd., and especially 325, and *Play of Animals* (Eng. trans.) in loc. and in the Preface by Baldwin, ix.

The terms semblance and appearance (*Schein* and *Erscheinung*) are also used in epistemology for that which seems or appears only, in contrast to that which also satisfies the demands of thought or real existence: a distinction covered by the terms *PHENOMENON* (q. v.) and *NOUMENON* (q. v.). On this meaning see the citations in Eisler, *Wörterb. d. philos. Begriffe*, 'Schein.' See also *KANTIAN TERMINOLOGY*, Glossary, 'Schein,' and 'Erscheinung.'

Literature: citations given under *PLAY*, *ART IMPULSE*, and *ART*, notably the works of K. LANGE, V. HARTMANN, and GROOS. See also SOURIAU, *La Suggestion dans l'Art* (1893); HIRN, *The Origins of Art*, 118 (with citation from Jouffroy, 80). (J.M.B., G.F.S.)

Semeiology and Semeiotic: see *SEMAN-TICS*.

Semi- or Half-conscious: see *SUBCON-SCIOUS*.

Seminal Reasons [Lat. *rationes seminales*, trans. of Gr. λόγος σπερματικός]. The forces, lodged in matter, by which natural effects result; active powers of nature, like heat and cold.

It is in virtue of them that the indefinite series of changes take place; they are, after being implanted in nature by God in the original act of creation, the causes of all subsequent combination and differentiation. They find their highest form of expression in the sex-process. As intermediary in the process of natural change and evolution, they are the media by which a universal is differentiated into individuals; these, however, in their specific nature, remain true to their genus. A scholastic term and concept. Cf. Harper, *The Philos. of the School*, ii. 731-2, iii. 412-13. See *LOGOS*, and *REALISM*.

The theory of λόγος σπερματικός found its way into Augustine under the form of the *ratio seminalis*; it was then taken up into the theory of creation by St. Thomas Aquinas, from whom the definition given is derived. The immediate creation had its cause in God, and had accordingly imparted to it the power of continuing the process of creation into the multiplicity of orders, genera, and species (and in the sex-processes) of

individuals. See references to St. Thomas in the passages of Harper referred to. (J.D.)

Semiology and Semiotic: see *SEMAN-TICS*.

Semi-Pelagianism: Ger. *Semi-Pelagianismus*; Fr. *semi-pélagianisme*; Ital. *semi-pelagianismo*. A proposed compromise between the opposing systems of Pelagianism and Augustinianism, in which the freedom of the human will is maintained in connection with a modified doctrine of human ability, by virtue of which the necessity of co-operant grace is admitted as a condition of man's salvation. See *PELAGIANISM*.

In spite of the great part which Semi-Pelagianism has played in the doctrinal history of the Christian Church, it nevertheless seems to be infected with the inherent weakness of compromises in general. As a doctrinal position, it embodies no new spiritual insight. It would seem necessary, in order to attain a real ground of unity between the opposing views, to reach some conception of the relation between the divine and human agencies which would harmonize them without involving the virtual suppression of either.

Literature: see *AUGUSTINIANISM*, *PELAGIANISM*, *ARMINIANISM*, and *JANSENISM*. (A.T.O.)

Seneca, Lucius Annaeus. (cir. 4 B.C.-65 A.D.). Born at Corduba, Spain, he was educated at Rome, his father being a man of literary tastes, wealth, and influence. Trained especially in rhetoric. Travelled in Greece. Practised oratory in Rome with great success. Banished to Corsica, 41-9 A.D. Became tutor, 49 A.D., to Domitius (afterwards Emperor Nero), the son of Claudius. Most of his literary activity belongs to this period. Consul in 56 A.D. Committed suicide at Nero's order, 65 A.D. See 'Stoics' under *SCHOOLS OF GREECE*, III.

Senescence [Lat. *senescere*, to grow old]: Ger. *Greisenhaftigkeit*, *Senescenz*; Fr. *senescence*; Ital. *senescenza*, *senilità*. The physical and mental changes attendant upon old age.

No definite age can be set for the beginning of senescence, but it may be said in ordinary cases to begin between fifty-five and sixty years for women, and between sixty and sixty-five for men, such years being fixed relatively to the termination of full sexual vigour. The physical symptoms of old age are many and characteristic; a general tendency to atrophy is observable and the diminution of elasticity of the blood-vessels (termed arterio-sclerosis) is a most important change. On the mental side the senses lose their delicacy, sight and

hearing being particularly affected. The memory becomes weaker, especially for recent events; apathy and weakness of will, lack of originality and receptiveness are apparent. 'Physiological senility typically means no reproductive power, greatly lessened affective faculty, diminished power of attention and memory, diminished desire and power to energize mentally and bodily, lower imagination and enthusiasm, lessened adaptability to change, greater slowness of mental action, slower and less vigorous speech as well as ideation' (Clouston). Apart from these normal changes there are psychoses especially characteristic of old age. The organic rather than the functional psychoses are typical of this period. In senile insanity heredity is a relatively small factor; for those with marked hereditary neurosis are apt to exhibit mental abnormality in earlier periods of life. An early senility is itself frequently a mark of a neurotic diathesis.

In senescence there is a strong tendency to chronic, progressive decline, and the insanities of old age approximate to the dementia type. The term 'senile dementia' refers to the typical psychosis of this form (see DEMENTIA). Insanities with a marked sexual aspect, delusions of suspicions concerning property, transitory deliria, and progressive mental deterioration, are typical characteristics in senile insanity. Cases of senile insanity, however, vary considerably in their symptoms; some are depressed and melancholic, the grief being often of an automatic type and not deeply felt inwardly; others are maniacal and subject to sudden outbursts of homicidal or destructive tendencies; while motor restlessness, constant motion with little rest or sleep, is a very typical symptom. Throughout, a forgetfulness, lack of appreciation of one's surroundings, degradation of habits, accompany the progressive dementia of the insane dotard.

Literature: NOTHLI, Ueber die Dementia senilis (1895). (J.J.)

Sensal [Lat. *sensus*, a sense]. (1) SENSUOUS (q. v., also for foreign equivalents); belonging to or derived from sense.

J. Grote speaks (*Explor. Philosophica*, ii. 156, 158) of 'sensal' intuition and knowledge; he used also the term sensitive.

(2) Concerned, not with the sound or form, i. e. the strictly verbal character of a word, sentence, or question, but with its import or purport.

Aristotle's division of definitions into 'verbal' and 'real' might be more properly translated

'sensal' and 'real.' So in J. S. Mill's contention (*System of Logic*, chap. vi. § 4) that 'an essential proposition . . . is one which is purely verbal,' i. e. concerned merely with the sense in which it is used, 'verbal' would become 'sensal.' This meaning is suggested by the present writer. Cf. VERBAL (also for foreign equivalents for meaning 2). (V.W., G.F.S.)

Sensation (1) and (2) **Sense** [Lat. *sensus*, a sense]: Ger. (1) *Empfindung*, (2) *Sinn*; Fr. (1) *sensation*, (2) *sens*; Ital. (1) *sensazione*, (2) *senso*. (1) That mode of consciousness which can only be accounted for by the present operation of an external stimulus upon the nervous system, or some equivalent condition.

(2) The specialized nervous apparatus and psychological process by the stimulation of which qualitatively distinct sensations are produced. Cf. SENSE ORGAN.

The verb form 'to sense' is sometimes used with the meaning to apprehend by sensation. The term 'sense process' is applied to the psychophysical function involved.

The word equivalent in the definition of sensation keeps the definition to those psychophysical processes which are normally due to actual stimulation, though in certain cases, such as sense illusions, delirium, &c., the stimulus may not be present. It excludes the cerebral processes belonging to reproductions, images, &c., aroused normally in the absence of peripheral stimulation. To call the mental states associated with these latter processes 'cerebrally initiated sensations,' as is done by certain recent writers (Kölpe), is to destroy a valuable historical distinction which has been maintained with fair consistency from the beginning of psychological inquiry.

The use of the term sense as equivalent to consciousness, as in the phrases 'time-sense,' 'sense of responsibility,' &c., is confusing and inaccurate.

The purely psychical characters of sensation, considered without reference to the conditions of its production, are treated under the topics PERCEPTION, IMAGE, and SENSORY ELEMENTS. The definition here given, though it is not strictly psychological, forms a good starting-point for further discussion. Cf. QUALITY, VIVIDNESS, PSYCHOPHYSICS, and the different sense topics, HEARING, VISION, &c.

(G.F.S.—J.M.B.)

Sensationalism [Lat. *sensus*, a sense]: Ger. *Sensualismus*; Fr. *sensationisme* (*sensualisme* is often used, as is its English equivalent—J.M.B.); Ital. *sensismo*. The theory that all knowledge originates in sensations; that all

cognitions, even reflective ideas and so-called intuitions, can be traced back to elementary sensations.

Historically, it is generally combined with ASSOCIATIONALISM (q. v.). In an ethical sense (for which, however, in English the term sensualism is more often used) it means that all moral values, or goods, are ultimately reducible to states of feeling which, psychologically, determine the will: Epicureanism.

In the first place it is a theory of the *origin* of knowledge, yet since questions arise (a) as to whether truth and certainty exist beyond sensation (in the derived forms), or are restricted to sensation, and (b) whether any truth can be found in purely immediate sensation, it comes to be also a theory regarding the validity of knowledge-forms, and as such is often used as synonymous with EMPIRICISM (q. v.).

Some of the Sophists (Protagoras, in particular, to all appearance) applied the conception of Heraclitus, that all is becoming, in such a way as to give validity, on the side of the knowing process, only to that which is in itself changing and partakes of motion, viz. sense. (But this may be merely the Platonic interpretation in *Theaetetus*.) Aristippus, the founder of the Cyrenaic school, taught most definitely that our knowledge is restricted to sensations. The Stoics asserted the idea of the origin of knowledge in sensations, but not its restriction to them. With them originated the famous simile that the soul is at first a blank tablet (see TABULA RASA) on which the outer world imprints its signs (Windelband, *Hist. of Philos.*, 203).

While the Stoics gave validity to the general ideas which result from perceptions, especially to those ideas which develop in all men alike, the Epicureans held that certainty is found conjoined with the necessity and clearness with which sensations force themselves upon us.

Some of the Latin fathers adopted this sensationalism as a basis for dogmatic orthodoxy. Since the soul in itself is limited to sensations, it cannot acquire the idea of God, salvation, or immortality. Hence the need of revelation to make known and valid these ideas. The Neo-Platonic and Scholastic philosophy universally admits a rational knowledge over and above sensation (in some Nominalists, however, the individual or real appears to have been identified with the individual presented to sense; but this doctrine left next to no impress). Hobbes is the founder

of modern sensationalism, which he conjoined to his theory of moving body as the seat and the source of all sensation. Locke holds to reflection, besides sensation; the former gives us knowledge of our own or inner powers, like memory, judging, &c.; but sensation is the sole source of knowledge of the external world. In three ways Locke's sensationalism was highly influential in settling the problems of later epistemology. (a) He taught the doctrine of 'simple ideas,' or elementary sensations. While he himself attributed positive value to relations, and to general ideas (at least in mathematics), his standpoint raised the question of the possibility and value of relations, and led Hume to his scepticism—to his substitution of the subjective principle of habit for the objective principle of causality. (b) He assumed (after the manner of Hobbes, but with less emphasis upon motion) atoms as the real ground and cause of sensations; but was logical enough to see that if our knowledge is limited to sensation, their existence can be asserted only hypothetically—though it was rather substance or substrate (whose relationship to physical atoms he seems never to have fairly faced) the existence of which is inferential, as the *unknown* cause. Hence the problem of reconciling physical science and sensationalism. (c) He defined knowledge as agreement (relationship) of ideas, and yet, in places, limited *certain* knowledge to the immediately experienced sensation. Hence the problem of knowledge as judgment, and the relation of this to sensation. While the French school, through the influence of Voltaire and Condillac, translated Locke's wavering sensationalism into a thoroughgoing system, and made it the fashionable philosophy of the ENLIGHTENMENT (q. v.), it is Hume who, realizing the epistemological and metaphysical consequences of it, continues the main line of thought. Kant, stirred directly by Hume, revises the empiricism of one period of his thought, gives up his naïve assumption that the object as such can be given in sense, and reduces sense to one co-ordinate factor in knowledge, that which gives its matter, which, however, is chaotic and disconnected till acted upon by the forms of sense and the categories of the understanding. While it is perhaps too much to say that, since his time, sensationalism is a historic anachronism (since, for example, Spencer holds it and even tries to combine it with the results of physical science), yet it is certain that he weakened greatly the concep-

tion of the origin of knowledge through atomic, disconnected sensations; and, for the most part, 19th-century sensationalism is simply a popular survival of the philosophy of the Enlightenment. (J.D.)

Sense: see SENSATION, and SIGNIFICATION; and cf. SIGNIFICS (1, a).

Sense (spiritual): Ger. *geistiger Sinn*; Fr. *sens spirituel*; Ital. *senso spirituale*. A function thought to be analogous to ordinary sensation, by which the soul is alleged to apprehend spiritual truth immediately.

The existence of a spiritual sense, different from the ordinary forms of cognition, is held by religionists of the mystical school generally, and as uniformly denied by those of scholastic and naturalistic tendencies. In one form it seems to be involved in the Christian doctrine of the new birth. Jonathan Edwards, in his sermon on Spiritual Light and in other places, calls it a 'sense of the heart,' and ascribes to it the perception of spiritual beauty or excellence. (A.T.O.)

Sense Discrimination: Ger. *Unterschieds-empfindlichkeit*; Fr. *discrimination, sensibilité aux différences*; Ital. *sensibilità di differenza* (or *distintiva*—E.M.). A term used by Fechner to cover the introspection of different sense-experiences and the apprehension of their difference.

We speak of a qualitative, intensive, extensive, and temporal sense discrimination, as we speak of a qualitative, &c., SENSIBILITY (q. v.). The aim of all measurements of it is the ascertainment of the difference threshold, or the apparent equality of two stimulus differences, just as the aim of all measurements of SENSIBILITY (q. v.) is the ascertainment of the stimulus threshold, or the apparent equality of two stimuli. Cf. DIFFERENCE (method of least noticeable).

Literature: FECHNER, *Elem. d. Psychophysik*, i. (1889) 47; G. E. MÜLLER, *Zur Grundl. d. Psychophysik* (1878), 1; KÜLPE, *Outlines of Psychol.*, 31, 48f.; WUNDT, *Physiol. Psychol.*, i. (1893) 336; FULLERTON and CATTELL, *The Perception of Small Differences*. Cf. PSYCHO-PHYSICAL MEASUREMENT METHODS. (E.B.T.)

The form 'sensible discrimination' is used by E.B.T., who however personally prefers 'differential SENSITIVITY' (q. v.), but it is not endorsed by the other authorities of this work. It is recommended that 'sense' be used generally instead of 'sensible'—meaning pertaining or belonging to the senses—as in the terms 'sense experience,' 'sense perception,' &c.

(J.M.B., G.F.S., H.C.W.)

Sense Illusion: Ger. *Sinnestäuschung*; Fr. *illusion des sens*; Ital. *illusione dei sensi*. Constant errors of sense perception.

Such illusions frequently arise from the nature of the sense apparatus, and are thus distinguished as a class from ILLUSION (q. v.) in general, which is a mistaken mental construction. They are also normal and regular, and thus common to different individuals, though not always of the same magnitude nor invariably present. Certain great cases, such as OPTICAL ILLUSIONS (q. v.) of form, ILLUSIONS OF MOTION AND MOVEMENT (q. v.), illusions of colour CONTRAST (q. v.), &c., lie on the borderland, and theories assign them variously to one class or the other. In case sense illusions are included in the larger category, it will still remain true that they are distinguished as phenomena of common and constant character, largely independent of mental context.

Literature: as given under HALLUCINATION, and under the topics cited; also TANZI, *Riv. di Patol. Nerv. e Ment.*, 1901. (J.M.B., H.C.W.)

Sense Intuition: see INTUITION (1).

Sense Organs: Ger. *Sinnesorgane*; Fr. *organes des sens*; Ital. *organi dei sensi*. Mechanisms specialized for the reception of the different stimulations of sense, called also peripheral END-ORGANS (q. v.). (C.F.H.)

Sense Process: see SENSATION (2).

Sensibility: Ger. (1) *Empfindlichkeit, Sensibilität*, (2) *Empfindsamkeit*; Fr. *sensibilité*; Ital. *sensibilità*. (1) The abstract term corresponding to the more concrete name sensation, and properly signifying the capacity of experiencing sensations.

(2) Used also in a more popular sense for susceptibility to pleasure, pain, and emotion, with special reference to the comparative readiness with which these states are induced and the intensity which they assume in different individuals.

(3) Equivalent to AFFECTION (q. v.).

The usage given first is recommended: see, however, under SENSITIVITY. (J.M.B., G.F.S.)

Sensibility (disorders of): Ger. (*Störungen der*) *Empfindlichkeit*; Fr. (*troubles de la*) *sensibilité*; Ital. (*disturbi della*) *sensibilità*. For definition see SENSIBILITY (1).

Disorders in the field of sensibility are generally described according to the special sense affected: see HEARING (defects of), VISION (defects of). Of these sight and hearing offer the most variable as well as the most usual instances. Absence of smell or of taste, or a limited range or perverted action of smell

or taste is relatively infrequent. Abnormal conditions of the skin and the tissues concerned in yielding sensations of movement are often called disturbances of SENSIBILITY, ANAESTHESIAS, and PARAESTHESIAS (see those terms); while disturbances of general sensibility refer more particularly to unusual sensations from the viscera and the complex of subconscious impressions which influence the sense of well- or ill-being. Painful and unpleasant feelings are particularly to be considered in this group.

Regarding abnormalities of sensibility common to all senses it may be noted that they fall into (a) cases of increased excitability or hyperaesthesia, a condition in which a stimulus much slighter than would ordinarily arouse consciousness is perceived, or in which ordinary stimuli are perceived with unusual vividness, and degrees of stimulation, ordinarily not unpleasant, become painful; (b) cases of more or less marked dulling of sensibility, or, when partial, hyperaesthesia; when complete (or not rigidly specified), anaesthesia, a condition the reverse of the former; (c) cases of disturbed or perverted sensibility or paraesthesia, a condition in which stimuli produce an unusual or morbid effect, or in which subjective or false sensations arise. SYNAESTHESIA (q. v.) is a name given to unusual associations between sense impressions whereby, e. g., the sound of a life when heard will arouse the appearance of a blue colour. The typical abnormalities of sensibility may be of a permanent character and be due to organic causes, but functional and temporary disorders of sensibility form a very numerous class.

Organic defects may depend upon disease or injury or faulty development of (portions of) the terminal sense organ or their accessory parts; upon interruption to the normal conductivity of the sensory nerve; or upon disorders of the centres; while in functional disorders the action of one or other of these elements is interfered with either by specific nervous disturbance or indirectly by a defect in the quality or quantity of nutritional blood-supply. Blindness may be due to opacity of the cornea, to a destruction or alteration of the rod and cone layer of the retina, to a degeneration of the optic nerve, or to injury to the central nervous system; and a similar range of causes of deafness or of tactile anaesthesia may be demonstrated. Colour-blindness is a good instance of a more special defect due to some unknown modification of terminal (or central) elements, while HEMI-

ANOPSIA (q. v.), deafness for low or high tones only, and anaesthesias in limited skin areas, illustrate partial sense defects. Disturbances of sensibility must be distinguished from erroneous inferences based upon them; i. e. from illusions and hallucinations; although the distinction is not always easy to draw and many forms of illusions involve and depend upon a sensory factor. The apparent bending of a spoon, half immersed in water, the doubling of a pea rolled between the crossed fingers, involve no disturbance of sensibility; but this can hardly be said of negative after-images, of the apparent coldness of lukewarm water to the hand that has just been in hot water, and so on. These normal variations of sensibility in the same individual are well recognized. The variations between individuals are no less so, and appear in the results of tests made upon any considerable number of individuals. Subnormal and supernormal efficiency, with regard to any sense, may thus be readily established. It is also essential to distinguish between abnormal and disordered power to respond to a stimulus, and a similar incapacity or difficulty in distinguishing between slightly different stimuli. See TESTS (psychophysical).

Among disorders of sensibility, not affecting the more usually recognized special senses, may be mentioned disorders of the muscular sense, or muscular anaesthesia (see ATAXIA), whereby the ordinary sensations which direct movement are interfered with, or whereby a movement when made gives no report of itself (except through the eye); and disorders of the sense of equilibrium producing various forms of dizziness. The various pains accompanying illness, such as intestinal pressure, heartburn, headache, pains of inflammation, bruises, swellings, ulcerations, &c., contribute more or less unusual forms of sensation. The sensations of cold perspiration, of blushing, of shivering or creeping of the skin, of chill and fever, of thirst and hunger, suggest other forms of general sensibility, which may present abnormal conditions in disease. The rôle of such sensations, when subjectively aroused in shaping illusions or HALLUCINATIONS (q. v.) in insanity, is an important one. (J.J.)

Sensible : see SENSE DISCRIMINATION, ad fin.

Sensible Discrimination : see SENSE DISCRIMINATION.

Sensilla : see ANTENNA.

Sensitive : see MEDIUM; and cf. PSYCHIC RESEARCH.

Sensitiveness [Lat. *sensus*]: Ger. (1) *Reizbarkeit*, (2) *Erregbarkeit*; Fr. *nature sensitive*; Ital. *natura sensitiva, eccitabilità*. (1) Excitability, nervous or mental.

The term is more properly limited to mental responsiveness to stimulations, especially to those of the affective order; the term irritability is better for nervous excitability.

(2) Delicacy of appreciation and response to situations, statements, &c., having a possible personal reference, covering SENSIBILITY (2). (J.M.B.)

Sensitivity [Lat. *sentire*, to know, perceive]: Ger. *Empfindlichkeit*; Fr. *sensibilité*; Ital. *sensibilità, sensitività*. The capacity of experiencing and communicating sensations. The writer suggests 'liminal sensitivity' as contrasted with 'differential sensitivity' [which he suggests for SENSE DISCRIMINATION (q.v.)—J.M.B.].

It may be subdivided into (a) *modal sensitivity*, which is measured by the number of sensations given with (or possible to) a particular sense, and (b) *sensibility*, which is measured in terms of the attribute predicable of the separate sensations.

Thus the modal sensitivity of the skin is determined when we have discovered and tabulated all the simple sense-qualities that can arise from cutaneous stimulation (pressure, warmth, cold, pain). Where there are a large number of such qualities, forming a sense-series (as in the cases of sight and hearing), we must determine further the limits of sensation-arousal (liminal and terminal sensitivity). Sensibility is divided into qualitative, intensive, extensive, and temporal sensibility. Thus it would be a test of qualitative sensibility to ask how many air-vibrations are necessary to the qualitative identification of the tone to which their period corresponds. If the test is one of discrimination of sensations within the limits of modal sensitivity, we speak of the SENSE (or 'sensible'—E.B.T.) DISCRIMINATION (q.v.) of qualities, intensities, &c. See also THRESHOLD, LIMEN, and PSYCHOPHYSICAL MEASUREMENT METHODS.

Literature: KÜLPE, *Outlines of Psychol.*, 33 ff.; GALTON, *Inquiries into Human Faculty* (1883), 30. (E.B.T.)

It would seem to be impossible, as well as inadvisable, to change the meaning of the term SENSIBILITY (q.v., 1). It is not only historically fixed in English (it is universal in pathological treatises), but it is the recognized translation of *Empfindlichkeit*. It would accordingly be preferable to make sensibility

the broader and 'sensitivity' the narrower term, if it be deemed advisable to fix the narrower meaning by a special word. The present writers do not see the need of the two terms, as distinction of 'quality'—as well within the same as between the different senses—is both adequate and true to the facts.

(J.M.B., G.F.S., H.C.W.)

Sensori-motor: Ger. *sensorimotorisch*; Fr. *sensori-moteur*; Ital. *senso-motorio*. Applied to action considered as following upon sensation. Cf. IDEO-MOTOR. (J.M.B.)

Sensorium [Lat. *sensus*, sense]: Ger. *Sensorium*; Fr. *sensorio*; Ital. (1) *sensorio comune*, (2) *sensorio*. (1) The grey matter of the cerebral cortex, the supposed physical seat of mental processes.

(2) In general, the whole sense-mechanism of the organism; the nervous system with its sensory attachments. (E.B.T.)

The use of this term is not recommended. (C.L.F., J.M.B.)

Literature: for the word see DARWIN, *Expression of Emotions* (ed. 1890), 69; CARPENTER, *Ment. Physiol.* (1888), 109 ff.; LEWES, *Physiol. of Common Life* (1860), chap. viii. On the seat of consciousness see WALLER, *Human Physiol.*, 503; FOSTER, *Textbook of Physiol.*, Pt. III, 1117, 1118; BASTIAN, *Brain as Organ of Mind*, 589 ff.; SPENCER, *Princ. of Psychol.*, esp. i. chap. vi; SULLY, *The Human Mind*, i. 48 ff.; FLECHSIG, *Gehirn u. Seele* (1894 and 1896); WUNDT, *Physiol. Psychol.* (4th ed.), i. 213 ff.; EBBINGHAUS, *Psychologie*, i. 23 ff., 150 ff. (E.B.T.)

Sensory: Ger. *sensorisch*; Fr. *sensitif, sensoriel*; Ital. *sensoriale*. See MOTOR, and SENSORY AND MOTOR ELEMENTS.

Sensory Circle: Ger. *Empfindungskreis*; Fr. *cercle de sensation*; Ital. *circolo sensitivo*. The area within which it is impossible to distinguish two aesthesiometric compass-points as two. (E.C.S.)

This cutaneous area, it was supposed, contained the ramifications of a single nerve-fibre. The concept was used by E. H. Weber to explain his aesthesiometric results. See his 'Tastsinn u. Gemeingef.' in *Wagners Handwörterb. d. Physiol.*, III. ii. (1846) 527; Sanford, *Course in Exper. Psychol.*, expt. 7; Wundt, *Physiol. Psychol.* (4th ed.), ii. 13.

It was also supposed to give the unit of local signature upon the skin; see LOCAL SIGN. Cf. Wundt, *Physiol. Psychol.* (4th ed.), ii. 36, 39.

The term is also used of the retina. Cf. C. du Bois-Reymond, *Ueber d. Zahl d. Empfindungs-*

kreise in d. Netzhaut, Diss. (Berlin, 1881), and Wundt, *Physiol. Psychol.* (4th ed.), ii. 101, 105. (E.B.T.)

Recent investigations, however, which show the extreme relativity of the area as thus determined, have tended to discredit both of the suppositions mentioned above. See Tawney, *Philos. Stud.* (1897), xiii. 163 ff., also in *Princeton Contrib. to Psychol.* (1897), ii. 1 ff., and *Amer. Natural.* (1897), xxxi. 820 ff.; Tawney and Hodge, *Psychol. Rev.* (1897), iv. 591 ff.; Henri, *Rev. Philos.* (1897), xliii. 333 ff. (J.M.B.)

Sensory (1) and (2) **Motor Elements**: Ger. *sensorische und motorische Elemente*; Fr. *éléments sensoriels et moteurs*; Ital. *elementi sensoriali e motori*. (1) Those qualities of presentation which can only be accounted for by tracing them to the present or previous operation of an external stimulus. A mental image is composed of sensory elements, although it arises independently of the present operation of an external stimulus.

Both the percept as such and the image contains sensory elements. In the case of the percept the sensory elements are present in the form of actual sensations, involving the present operation of an external stimulus or some equivalent condition. In the case of the image the sensory elements are the reproduced qualities of previous sensational experience. When I look at a red cloth with my bodily eye, I have an actual sensation of redness. When I afterwards mentally call up the image of the red cloth, the redness is again present to consciousness in its peculiar and distinctive quality. It is a sensory element, though not an actual sensation. It should be noted that thinking of a sensation or sensible quality by no means implies the presence in consciousness of a corresponding sensory element. People can think of red or blue who have no power of visualizing these colours. They can attach distinctive meanings to the words red or blue without *imagining* these sensible qualities as such. (G.F.S., J.M.B.)

(2) Sensory elements which arise from the function of the **MOTOR** (q. v.) apparatus.

It is convenient to preserve the distinction between sensory and motor elements; but their essential nature—that of being sensational—is the same. The sensations coming from movement may thus be separated off.

(J.M.B., G.F.S.)

Sensual: see **SENSUOUS** AND **SENSUAL**.

Sensualism: Ger. *Sensualismus*; Fr. *sensualisme*; Ital. *sensualismo*. Any form, theory,

or practice which sets high value upon, or issues in, (1) the sensual, (2) the **SENSUOUS** (q. v.).

The first is the legitimate meaning; the proper designation for the second is **SENSATIONALISM** (q. v.), which has largely replaced sensualism in English; *Sensualismus* still appears more regularly in German, however. (J.M.B.)

Sensualism (in aesthetics). Emphasis upon the sensuous element in the aesthetic object, and the derivation of aesthetic value principally from this element (e. g. colour, tone, &c.).

It is contrasted, from different points of view, with **FORMALISM**, **INTELLECTUALISM**, and **IDEALISM** (see those terms). The term may be applied to the view of Allen (*Physiol. Aesth.*, 1877).

Literature: see under the topics cited above. (J.H.T.)

Sensualism (in ethics). The popular use of the term is to denote a low or depraved form of moral theory, according to which indulgence in the more gross forms of pleasure is made the chief end of life. (J.D.)

Sensuous (1) and (2) **Sensual** [Lat. *sensus*, sense]: Ger. (1) *sinnlich*, (2) *fleischlich*; Fr. (1) no single term, (2) *sensuel*; Ital. (1) no single term, (2) *sensuale*. (1) Pertaining, belonging, or appealing to the senses; often equivalent to sense- (in compounds) and to **SENSORY** (q. v.).

(2) Pertaining, appealing, or ministering to what is fleshly and unchaste, especially to the sexual.

These words are often confused, sensual being misused for sensuous; e. g. by Dabney, *Sensualistic Philos. in the 19th Century*, and by the translator of Ziehen, *Introd. to Physiol. Psychol.* (1st ed.). (J.M.B.)

Sentence Method: see **WORD METHOD**, and **ALPHABET METHOD**.

Sentience [Lat. *sentiens*, from *sentire*, to feel]: no single foreign terms. (1) The reverse of the meaning below, sentience being elementary consciousness, and sensibility the correlative nervous process.

(2) The nervous function which attaches peculiarly to consciousness; the physical basis of sensibility; the central nervous process supposed to be due to an activity of the cells of the grey matter of the brain.

The first usage is that of Lewes (*Physical Basis of Mind*, 222; cf. also Sergi, *Psychol. physiol.*, 12); the second was suggested by the present writer (*Handb. of Psychol.*, *Feeling*

and Will, chap. ii). It seems, however, somewhat strained to use either term, *sentence* or *sensibility*, of nervous action. **NEUROSIS** (q.v.) is being used, but generally in too restricted a sense. If both *sentence* and *sensibility* be preserved, the former should in all cases be carefully defined: possibly it were better to drop it as a technical term. (J.M.B.)

Sentiment [Lat. *sentire*, to feel]: Ger. *höheres Gefühl*; Fr. *sentiment* (*esthétique*, &c.); Ital. *sentimentalità*. An emotional disposition having reference to an object or class of objects represented by a more or less complex system of ideas. See **DISPOSITION**, and cf. **PASSION**.

A sentiment cannot be felt all at once. It is a general susceptibility to manifold kinds of emotion varying with circumstances. Thus friendship is a sentiment, and is manifested in the sorrow of parting with one's friend. The joy of meeting him after prolonged separation, jealousy of those who engross his interest so as to exclude us from it, hope for his success, fear when he is in danger, anger against his enemies—all these emotions belong to the sentiment of friendship. But they cannot all be felt at once. On the other hand, not all emotional dispositions are sentiment, but only those which have a complexity due to the development of ideational consciousness. Sentiment and desire, in the strict sense of the word, arise at about the same level of psychical development. We might say that a cat has a malevolent sentiment, because it shows signs of anger whenever it sees the child who is in the habit of teasing it; yet it would be the extreme case. (G.F.S., J.M.B.)

The sentiments usually distinguished as notable and representing important movements in mental history are the **AESTHETIC** (q.v.; cf. **BEAUTY**, **ART**, and **SYMPATHY**, aesthetic—under which the recent theory, which, under the term *Einfühlung*, requires the revival of affective states as such, is noticed); the Religious (see the various topics **RELIGION**, especially psychology of), the Ethical (see **ETHICS**, **ETHICAL THEORIES**, and the various topics **MORAL**). A less exactly defined sphere of sentiment is the social, in which we have a sentiment or disposition for social intercourse in general (see especially **SOCIAL PSYCHOLOGY**, **SOCIAL ORGANIZATION**, **SOLIDARITY**, and **SOCIUS**).

The adjective 'sentimental,'—and especially the verbal noun 'sentimentality'—carries the slightly derogatory meaning of over-emphasis upon sentiment or over-susceptibility to it.

(J.M.B.)

Sentiment (aesthetic): Ger. *ästhetisches Gefühl*; Fr. *sentiment esthétique*; Ital. *sentimento estetico*. (1) **SENTIMENT** (q.v.) directed towards what is aesthetic. Cf. **AESTHETIC** (with topics cited there), **BEAUTY**, and **SYMPATHY** (aesthetic). (J.M.B.)

(2) Occasionally used in an objective sense closely equivalent to 'aesthetic expression,' as in 'the grace and sentiment of French architecture.'

Literature: **RIBOT**, *Psychol. of the Emotions* (1897); **LADD**, *Psychol., Descrip. and Explan.* (1894), and other textbooks of psychology. See also the citations under **AESTHETICS**. (J.R.A.)

Sentimental (and **-ity**): see **SENTIMENT**, ad fin.

Sentimental (in aesthetics): see **NAÏVE**.

Separation (in biology): see **ISOLATION**.

Septuagint [Lat. *septuaginta*, seventy]: Ger. *Septuaginta*; Fr. *version des Septante*; Ital. *versione dei Settanta*. A Greek version of the Hebrew Scriptures, in the Alexandrian dialect, said to have been produced at different times and by different translators during the 3rd century B.C., and embracing in order the Pentateuch, the Prophets, and the Hagiographa.

The Septuagint derives its name from the tradition, now discredited, that it was the work of seventy scholars working under the direction of Ptolemy Philadelphus, king of Egypt. It contains not only the Scriptures of the accepted canon, but a number of Apocryphal books. It is the source of the quotations in the New Testament, and had an important influence on the diction of the latter. It was the chief authoritative version of the early church till the appearance of the Latin Vulgate of St. Jerome.

Literature: **HORN**, *Introd.* (London, 1877); **A. GEIGER**, *Urschrift u. Übersetzungen d. Bibel* (Breslau, 1857); **SCHIERER**, *Jewish People in the Time of Jesus Christ* (Eng. trans.), ii. 159–68. (A.T.O.)

Sequence: see **CONSEQUENCE**.

Serf and Serfdom: see **SERVITUDE**.

Serial Resemblance: see **RESEMBLANCE** (table, III).

Series [Lat. *series*, succession]: Ger. *Serie*; Fr. *série*; Ital. *serie*. A group of objects linearly related. (C.S.P.)

Used in psychology for a succession of associated or successive elements of content; cf. **HANDWRITING**, and **MOVEMENT**, for instances. (J.M.B.)

Services [Lat. *servitium*, also Med. Lat.

SERVITUDE

servicium]: Ger. (*Dienst*-)Leistungen; Fr. *services économiques*; Ital. *servigi*. Means of enjoyment when the processes of production and consumption are indistinguishable in time.

There has been a long and rather profitless discussion of the question whether services should be included in wealth. The answer, indicated by the analyses of Newcomb and Fisher, is that in measurements of wealth as a flow services should be included; but that in measurements of wealth as a fund, they should not be included. (A.T.H.)

Servitude [Lat. *servitudo*, slavery]: Ger. *Sklaverei*; Fr. *servitude*; Ital. *schiavitù*. The state of a slave; the state in which a human being is an object of property, a chattel.

Slavery is one of the oldest and most widely diffused of social phenomena. There may have been a period antecedent to the rise of slavery in which the enemy or stranger (once almost similar characters) was invariably killed and perhaps eaten. But when this first stage of savage life had been surmounted, slavery seems to have been universally recognized. At first the recognition of mutual rights and duties was confined to the small group of persons united by some real or fictitious kinship. As the primitive community enlarged itself, the moral sphere was enlarged also. Men acknowledged the claims of members of the same tribe or city, and even of the same nation, but very faintly recognized those of other aliens. Even Christians, until comparatively recent times, scarcely recognized any duty towards Moslems or heathens beyond that of converting them when possible. Thus until the 18th century most civilized men considered that a great part of the human race might lawfully be held in slavery and treated as articles of property. Aristotle defended slavery under certain circumstances, and the Christian Church did not condemn it.

In the most logical form of slavery the slave is simply an object of property, and as such may be used or destroyed at the pleasure of his owner. Such was the position of the slave in the primitive Roman law. But as such a relation between human beings is repugnant to the better feelings of civilized people, religion and morals tended to mitigate the position of the slave. In Greece and Rome the slave was regarded as a member of the family, and might by emancipation acquire civil and even political rights. The Athenian law and the later Roman law protected him from extreme brutality on the part of his

master, but without recognizing him as a legal person or empowering him to defend his own cause. In Greek and Roman society many slaves were highly educated, and were employed in what we should term the liberal professions. Thus they were often the equals of their masters, and the relations between master and slave were often friendly and confidential. But slaves employed in agriculture on large estates were frequently victims of atrocious cruelty. Such slaves took the chief part in the servile wars which mark the last age of the Roman republic. Under the emperors rural slavery was very generally transformed into serfdom. Without ceasing to be a slave, the cultivator acquired a holding and a separate abode. Although still legally at the discretion of his master, he had a freer and more human life than a plantation slave working in a gang and shut up at night in a prison. When the empire became Christian, the slave's family ties, which the law had ignored, were recognized by religion. Serfdom survived the fall of the Roman empire. In Western Europe the bulk of the cultivators were serfs until the 13th century, when various causes produced a rapid diminution of serfdom. In Central Europe serfdom was common down to the French Revolution. In Russia it was only abolished by the Czar Alexander II in the year 1861. The distinguishing characteristic of serfdom as opposed to slavery is found in the customary rights of the serf. Although the serf and his tenement were regarded both by Roman and mediaeval lawyers as the property of the lord, he gradually acquired a customary right not to be disturbed in his holding so long as he rendered the customary payments and services. Thus the serf became a proprietor, although of a degraded kind. Mediaeval and modern law recognized his family relations, regarded him as responsible for crimes, and in relation to all men except his master treated him as virtually a free man. Thus the condition of the serf admitted of a certain degree of wellbeing.

Slavery, in the strict sense of the term, was common in the Roman empire down to its fall, and mediaeval and modern Christians felt no scruple about enslaving persons who were not Christian. In the interminable wars between Christians and Moslems the captives were frequently reduced to slavery, sometimes of the most cruel kind, such as slavery in the galleys. The discovery of the New World gave a powerful impulse to the use of slave labour in working mines and plantations.

All the colonizing peoples and their colonists have been equally guilty in this respect. All the brutalities of ancient slavery have been equalled in the history of the New World. The philanthropic movement of the 18th century led to the suppression first of the slave trade and then of slavery. Both were abolished in the French dominions at the time of the Revolution, although slavery was restored in the French colonies for a short time. In the British dominions the slave trade was abolished in 1807 and slavery in 1833. In the United States slavery was abolished in consequence of the Civil War of 1861-5. Slavery is no longer legal in the territory of any Christian state, although it constantly tends to reappear whenever a barbarous country is entered by white adventurers. Oriental slavery, not yet wholly suppressed in Mohammedan countries, has many peculiar features and a history of its own.

Literature: the classical literature of Greece and Rome abounds in passages illustrative of the position of slaves. Many are collected in the article 'Servus' in Smith's Dict. of Greek and Roman Antiquities. The legal position of the Roman slave is set forth in the Institutes of GAIUS and JUSTINIAN, and the effect of slavery upon Roman society and politics has been strongly depicted by MOMMSEN in his Hist. of Rome. Concerning mediaeval serfdom much will be found in FUSTEL DE COULANGES' great work *Les Origines des Inst. de l'ancienne France*; in VINOGRADOFF's *Villénage in England*; in POLLOCK and MAITLAND's *Hist. of English Law*; and in economic histories of the mediaeval period. The standard histories of the Spanish and English colonies in the New World, and books of travel in America in the 17th and 18th centuries, contain many facts about modern slavery. The Abolitionist movement in England and America produced a bulky literature of books, pamphlets, and official and parliamentary papers relating to slavery.

(F.C.M.)

Servitude (in law): Ger. *Dienstbarkeit*; Fr. *servitude*; Ital. *servitù*. A condition of service imposed upon a corporeal thing, in favour of one not its owner, whereby the thing is made liable to suffer something, or its owner is restrained from doing something.

Slavery in this sense is not a servitude; but if the owner of a slave grants a usufruct in him to another, such usufruct is a servitude. *Positive servitude*: one which involves a suffering something to be done. *Negative*

servitude: one which involves not doing something, which an owner otherwise could do. *Personal servitude*: one belonging to a certain person, without reference to his ownership of other property. *Praedial or real servitude*: one affecting a corporeal thing, and belonging to the owner of other property, as such owner.

This is a copious title in Roman law (see *Dig.*, viii. 1, *de Servitutibus*). The popular meaning of servitude as a *status* of personal subjection also often attaches to the term as used in law, e.g. in the Thirteenth Amendment to the Constitution of the United States.

Literature: MARKBY, *Elements of Law*, chap. x; HOLLAND, *Jurisprudence*, chap. xi. 188; Smith's Dict. of Greek and Roman Antiq., 'Servitude'; French Code Civil, Liv. II. tit. 3 and 4. (S.E.B.)

Sex [Lat. *sexus*, from *secare*, to cut]: Ger. *Geschlecht*; Fr. *sexe*; Ital. *Sesso*. The condition or quality of producing germ cells of one kind, either male or female. (C.S.M.)

Those organisms which produce ova (called oospheres in plants) are said to be of the female sex; those which produce spermatozoa (spermatozoids in plants), of the male sex; those which produce both ova and spermatozoa are HERMAPHRODITE (q.v.). In sexual reproduction the spermatozoon enters and fuses with the ovum (see FERTILIZATION); the spermatozoon is the active element in this process, the ovum being relatively passive or quiescent, and providing nutriment for the development of the resulting embryo. The characters of the reproductive cells themselves, and of the male and female organisms which bear them, are correlated with this division of labour between the two sexes. In the lower organisms such a differentiation may be little or not at all expressed; as for instance in the Protozoa and lower Algae, where the two cells which fuse in the fertilizing process may be quite similar. Whilst Butschli and Minot believe that the primary function of the sexual fusion is the 'rejuvenescence' of the reproductive cell, Weismann holds that the essential purpose of the process is the mingling of hereditary tendencies derived from each parent. Maupas' observations on Protozoa support the theory of 'rejuvenescence.' See AMPHIMIXIS, OVUM, and SPERMATOZOON. For bodily and mental sexual differences see SEXUAL CHARACTERS.

Literature: Y. DELAGE, *Structure du Protoplasma et Biol. Gén.* (1895); E. B. WILSON, *The Cell* (1896, 2nd ed. 1900); O. HERTWIG, *Die Zelle* (1893); A. WEISMANN, *Amphimixis*, &c., trans. in *Essays upon Heredity* (1892);

SEXES — SEXUAL CHARACTERS

M. MAUPAS, *Recherches expérimentales sur la Reproduction des Infusoires*, Arch. Zool. Expér., v. 6 (1888); GEDDES and THOMPSON, *The Evolution of Sex* (1889). (E.S.G.)

Sexes (psychology of): see **SEXUAL CHARACTERS**.

Sextus Empiricus. Lived about the latter half of the second century in Greece. He revived the scepticism of Pyrrho.

Sexual Characters: Ger. *Geschlechtscharaktere*; Fr. *caractères sexuels* (*primaires et secondaires*); Ital. *caratteri sessuali*. The physical and mental peculiarities which differentiate the sexes. (J.M.B.)

The physiological interest in sexual characteristics arises from the unlimited mental and emotional concomitants which differentiate the sexes. In the strictest sense, the organs concerned in reproduction, and their functional characteristics, constitute the 'primary' sexual characters; with these may be included—or assigned a special position—the organs of gestation and lactation in woman. All further differences of function and structure constitute 'secondary' sexual characters (a term first used by Hunter, 1728-93); while differences which are still further removed, and which are apparently derived or incidental concomitants of specifically secondary sexual characters, may properly be termed tertiary sexual characters (Ellis). The beard and the distribution of the hair, differences of larynx and voice, the rounding of outline due to the deposit of adipose tissue in the female, the larger muscular system and skeleton of the male, are examples of secondary sexual characters. The greater precocity of the girl, the greater emotional affectability of woman, the love of adornment, the greater dependence upon unanalysed impulses, in contrast to conscious logical motives, may be cited as instances of tertiary sexual characters.

The origin of secondary and tertiary sexual characters cannot be determined in all cases; many of them are such as were developed, or may readily be conceived to have been developed, by sexual selection, and result in making the sexes more attractive to each other; the woman more womanly, the man more manly. The personal, social, and industrial division of duties, both in primitive and in more developed forms of life, doubtless emphasized incipient masculine and feminine tendencies and introduced additional ones. Upon this basis are grafted the results of conventional differences of training, of social environment, and of racial and national ideals;

so that it is frequently difficult to determine how far tertiary sexual characters represent differences of original nature or of acquired nurture. Such differences are frequently determinable only on the basis of complex statistical data difficult to secure and to interpret.

Certain prominent or interesting differences may be enumerated as follows: the male is larger, his muscles and bony prominences are more defined; the female has a relatively long trunk and short limbs; in body-growth there is a period during puberty ($12\frac{1}{2}$ – $14\frac{1}{2}$ in Great Britain) when girls are taller and heavier than boys; the boy's year of most active growth is the sixteenth, the girl's the thirteenth or fourteenth; the woman reaches maturity at twenty years, the man, not until somewhat later; the greater brain-weight and cranial capacity of man, while obvious, are difficult to determine in independence of body-weight and size; the female pelvis presents distinctive features not found in the male; that the female body in many respects is more like that of the child (infantilism), and that it presents a lesser degree of variability (i.e. it presents greater organic conservatism), seems well established; woman shows a greater immunity from gross lesions of the nervous system than man; woman presents a greater power of resistance to disease and death, and thus has a greater longevity; the red corpuscles of the blood are more numerous in the male; his lung capacity is greater, but the costal breathing of woman, as opposed to the abdominal breathing of man, is generally regarded as an artificial effect of constricting dress. In pathological respects masculine and feminine susceptibility are measurably different; general paralysis is a typical nervous disorder of men, hysteria of women; differences in sense-endowment are difficult to substantiate, the marked prevalence of colour-blindness in men constituting an exception; the emotional susceptibility and variability of woman are greater, and appear in abnormal (mania, melancholia, violent outbursts, &c.) as well as in normal manifestations; the more sympathetic, less egoistical nature of woman and greater craving for regard as well as greater patience and sacrifice in devotion may also be noted; differences of intellectual endowment and tendencies doubtless exist, but are not readily summarized, and form part of the group in which it is particularly difficult to allow for the effects of education and convention. While such an eclectic summary does not convey an exact notion of

the relative importance of sex differentia, it may serve to indicate some of the rubrics which command present investigation. The general principles under which sex differences are viewed are everywhere important, and find a suitable representation in the best discussions. Another phase of the literature, which cannot be further referred to, is concerned with the social and industrial aspect of the occupations of the sexes and their adaptation to the conditions of modern society. The educational aspect of this general problem has for decades been prominent, and forms one of the several practical questions upon which the determination of derived characters has an important bearing.

Literature: HAVELOCK ELLIS, *Man and Woman* (1895), and *Studies in the Psychol. of Sex*, i (1898); H. CAMPBELL, *Differences in the Nervous Organization of Man and Woman* (1891); THOMAS, *Metabolism of the Sexes*, *Amer. J. of Sociol.*, iii, 31, and 754; ROMANES, *Nineteenth Cent.* (May, 1887); PLOSS and BARTELS, *Das Weib in der Natur-u. Völkerkunde* (3rd ed., 1891); MASON, *Woman's Share in Primitive Culture* (1894); HIGGINSON, *Common Sense about Woman* (1891); LOMBROSO and FERRERO, *La Donna* (1891); BALDWIN, art. *Woman*, in *Johnson's Univl. Cyc.*, suppl. vol. (1899). (J.J.)

Sexual Feeling: Ger. *geschlechtliches Gefühl*; Fr. *sentiment sexuel*; Ital. *sentimento sessuale*. A whole system of emotions and feelings which arise and develop in connection with the organic craving dependent on sexual relations. Cf. SEXUAL SENSATION, and SEXUAL CHARACTERS. (G.F.S.)

Sexual Reproduction: Ger. *geschlechtliche Fortpflanzung*; Fr. *reproduction sexuelle*; Ital. *riproduzione sessuale*. The multiplication of individuals of the same species by means of gonads (fertilized germ-cells, ova, and spermatozoa).

Synonymous with GAMOGENESIS (q. v.). See also FERTILIZATION, and SEX. (C.S.M.)

Sexual Selection: Ger. *sexuelle Auslese* (*Selektion*), *geschlechtliche Zuchtwahl*; Fr. *sélection sexuelle*; Ital. *selezione sessuale*. The more or less conscious selection of one mate by another, and its influence on subsequent evolution. See SELECTION (in biology, b), and FACTORS OF EVOLUTION.

Suggested and expounded by Charles Darwin as supplementary to natural selection, it has held its place in the theory of evolution. It is now generally held, however, that Darwin laid too much stress on the conscious prefer-

ence of the female for the male which she selects over others, as if she compared them before choosing. The theory, as at present held, makes the selection a simple response, largely of organic kind, to the increased sexual stimulation experienced by the female in the presence of the more attractive male. As pointed out by Hirn (as cited below, 201), this is not an essential difference for biology, but it is for the theory which finds the origin of art in this relation of the sexes. It has been argued by Hirn and Groos (and suggested by Guyau) that the native coyness of the female is correlative to the attractiveness of the male, and sexual selection operates largely by the overcoming of this native coyness.

Literature: that of EVOLUTION (q. v.), notably DARWIN, WALLACE, and the general expositions of CONN and HEADLEY. See also GROOS, *Play of Animals* (Eng. trans.); HIRN, *Origins of Art*, chap. xiv (reproducing an earlier Swedish work). (J.M.B., E.B.P.)

Sexual Sensation: Ger. *Sexualempfindung*; Fr. *sensation sexuelle*; Ital. *sensazione sessuale*. The ORGANIC SENSATION (q. v.) of SEX (q. v.). (J.M.B.)

Shaftesbury, Anthony Ashley-Cooper, third Earl of. (1671-1713.) Born in London, and educated under the supervision of Locke. He entered Parliament, 1693; lived in Holland, 1698-9; succeeded to the peerage, 1699; retired from public life upon the death of William III. He was one of the group of 'English moral philosophers'; see ETHICAL THEORIES (1), (c).

Shamanism [Pers. and Hindu *Shaman*, *idolater*]: Ger. *Schamanismus*; Fr. *chamanisme*; Ital. *sciamanismo*. The belief entertained by some North Asiatic and American tribes that the fortunes of life are chiefly determined by a group of inferior deities or spirits, who are for the most part evilly disposed, and whose worship is incantation.

The tribes in question believe in a supreme deity who is good. But they believe also that a class of inferior and malevolent spirits so dominate the lower world that man is largely at their mercy. The religious worship is therefore devised with reference to these evil spirits or devils, and consists in attempts to appease and propitiate them by means of spells and incantations.

Literature: TYLOR, *Primitive Culture* (1877); GARDNER, *Faiths of the World*; SOMMIER-STEPHEN, *In Siberia*. (A.T.O.)

Shame [ME. *shamen*]: Ger. *Scham*; Fr. *honte*, *pudeur* (physical); Ital. *vergogna*.

Lowered self-esteem felt with reference to something positive pertaining to self, and open to the knowledge or opinion of others.

The demarcation of shame off from the forms of shyness (MODESTY, COYNESS, and BASHFULNESS; see these terms) proceeds upon the positive and strong self-abasement which it involves, as contrasted with the hesitation, caution, and inhibition of those states of mind. While they seem to require only the consciousness of exposure to others, and, in the higher states (modesty), reflection upon this relation, shame includes a further sense of self-condemnation or conscious ill-desert. In general, shame arises when modesty and other sentiments of self-respect are violated. On the organic side, it is mainly revealed by the blush, which seems to connect it with bashfulness and coyness, for they also involve vaso-motor changes. The two classes of causes of shame are: (1) exposure in situations involving physical indelicacy, notably in matters concerning those bodily functions which are considered private. It is in this regard that shame approaches coyness, since the privacy of the physical functions centres about the privacy of sex. It is not coyness entirely, however, since the sense of self, involving responsibility and personal disgrace, enters into shame. (2) Exposure in situations of an intellectual and moral sort, in which (a) the simple weakness of the person is revealed, as in physical or moral cowardice; in which (b) there is disappointment of expectation; or in which (c) there is actual breach of social or moral prescription.

Literature: see under SHYNESS; a recent anthropological paper is ELLIS, *The Evolution of Modesty*, Psychol. Rev. (1899), vi. 134 ff. (J.M.B.)

Shamming: see MAKE-BELIEVE (1).

Shock (in medicine) [AS. *shakan*, to shake]: Ger. *Schock*; Fr. *choc*, *shock*; Ital. *colpo*, '*shock*.' A condition of sudden disturbance, mainly of an inhibitory character, affecting almost all the vital and nervous functions, following upon bodily injury or intense emotion.

The typical symptoms of shock, whether of physical or of mental origin, are in the nature of a profound interference with the functional activities of body and mind. The pulse and respiration are markedly lowered; the body temperature falls, and a cold perspiration ensues; the subject feels faint and sick; may be unconscious or but dimly realize his position; is apt to be anxious and appre-

hensive, and may be much excited. The psychological interest in this condition arises from the fact that purely or largely emotional causes may produce the same or nearly the same results as actual physical injury. In railway disasters or other conditions of great danger or fright, persons who have escaped without bodily injury often suffer severely from shock; while in surgical operations, in accidents, in battle, the emotional complications are admitted by all to be a most important factor in the resulting disabilities. Even death itself may result from purely emotional causes. Shock with excitement is often termed *eristhenic shock*. The mode of action of shock is not clearly determined, but its connection with an interference with the normal relations of inhibition, particularly as affecting the circulation, seems to be borne out by clinical and experimental evidence. The dazed condition at times observable in cases of shock has been regarded as akin to the state of hypnosis.

Literature: art. Shock from Fright, in Tuke's Dict. of Psychol. Med.; GROENIGEN, *Über den Schock* (1885). (J.J.)

Short Cut (in neurology and biology): Ger. *Abkürzung*; Fr. *condensation de l'ontogenèse* (Y.D.); Ital. *abbreviamento ontogenico*. Abbreviation of ontogenetic development by the omission of some of the stages required by the law of RECAPITULATION (q.v.). See also ONTOGENY, and cf. v. BAER'S LAW.

The term is used informally by Foster for the shorter of two alternative brain paths, and made a technical one in the above sense by the present writer.

Literature: FOSTER, Textbook of Physiol. (5th ed.), iii. 1062; BALDWIN, Ment. Devel. in the Child and the Race, chap. i. 74; BOSANQUET, Social Automatism, Mind, N.S., viii. (1899) 167 (who makes a social application). (J.M.B.)

Shyness or **Timidity** [ME. *shēy*, timid; Lat. *timidus*, fearful]: Ger. *Schamhaftigkeit*, *Verschämtheit* (K.G.); Fr. *timidité*; Ital. *timidità*. A state of more or less apprehension and caution in the presence of others, taking on various special forms, with special physical attitudes, according to the circumstances.

It is recommended that these terms denote the general condition and reaction of which BASHFULNESS, COYNESS, and MODESTY are special cases (see those terms). The physical reactions may well be known as shyness-reactions. Between shyness and timidity no distinction is attempted; yet the term shyness

is perhaps preferable, since timidity and timid are used sometimes for 'fear.'

Literature: DARWIN, Expression of the Emotions; MOSSO, Fear; GROOS, The Play of Animals, 243 f., 283 f.; DUGAS, La Timidité; H. CAMPBELL, Brit. Med. J., Sept. 26, 1896; BALDWIN, Ment. Devel. in the Child and the Race, chap. vi. § 5; Social and Eth. Interpret., chap. vi; HARTENBERG, Les timides et la timidité (1901). (J.M.B.)

Sibilants: see PHONETICS.

Sibylline Books [Lat. *sibyllinus*, pertaining to a sibyl]: Ger. *die Sibyllinischen Bücher*; Fr. *les livres sibyllins*; Ital. *i libri sibillini*. The books of prophecy which Herophile, the most famous of the ancient sibyls, is said to have sold to Tarquinius Superbus, and which were preserved by the Romans and consulted in urgent matters.

The Sibylline books were lost in the destruction of the temple of Jupiter by fire in 83 B.C. A new collection was made, which has also been lost. The extant twelve books of so-called Sibylline prophecies are of later and mostly spurious origin. (A.T.O.)

Side Window Experiment: Ger. *seitlicher Fensterversuch*; Fr. (not in use—L.M.); Ital. *esperimento della finestra laterale*. An experiment in binocular contrast: standing unsymmetrically with respect to a window, obtain double images of a white surface on a dark ground; the single image appears faintly blue (blue-green) on the window side, and faintly red (orange) on the other side.

Literature: FECHNER, Binoc. Sehen, 511 ff.; SANFORD, Course in Exper. Psychol., expt. 168. (E.B.T.—C.L.F.)

Sidgwick, Henry. (1838–1900.) Born in Yorkshire, England, educated at Rugby School and Trinity College, Cambridge, he became a fellow and lecturer at Trinity College in 1859, reader in moral science in 1875, professor of moral philosophy in Cambridge University, 1883. He was identified with the movement in England for the higher education of women, and especially with the interests of Newnham College for women, at Cambridge. His principal works are in ETHICS (q. v.) and politics, his position in ethics being that of a 'modified' utilitarian. Cf. UTILITARIANISM. He was one of the 'Consulting Editors' of this DICTIONARY. See an 'auto-historical' note in his *Methods of Ethics* (6th ed.); Hayward, *The Ethical Philosophy of Sidgwick* (1901), and L. Stephen, in *Dict. of Nat. Biog.*, Sup. iii, sub verbo.

Sighting Line: Ger. *Visirlinie*; Fr. *ligne*

de visée; Ital. *linea di sguardo*. The straight line connecting two luminous points which appear to be in exactly the same direction from the observer.

The sighting lines intersect at the centre of the image of the pupil made by the cornea (which is only 0.6 mm. in front of the true position of the pupil). The principal sighting line is practically identical with the principal ray of direction (line of sight).

Literature: HELMHOLTZ, Physiol. Optik (2nd ed.), 115, 127, 617, 672; SANFORD, Course in Exper. Psychol., 187; WUNDT, Physiol. Psychol. (4th ed.), ii. 106. (E.B.T.)

Sign [Lat. *signum*, a mark, a token]: Ger. *Zeichen*; Fr. *signe*; Ital. *segno*. (1) Anything which determines something else (its *interpretant*) to refer to an object to which itself refers (its *object*) in the same way, the interpretant becoming in turn a sign, and so on *ad infinitum*.

No doubt, intelligent consciousness must enter into the series. If the series of successive interpretants comes to an end, the sign is thereby rendered imperfect, at least. If, an interpretant idea having been determined in an individual consciousness, it determines no outward sign, but that consciousness becomes annihilated, or otherwise loses all memory or other significant effect of the sign, it becomes absolutely undiscoverable that there ever was such an idea in that consciousness; and in that case it is difficult to see how it could have any meaning to say that that consciousness ever had that idea, since the saying so would be an interpretant of that idea.

A sign is either an *icon*, an *index*, or a *symbol*. An *icon* is a sign which would possess the character which renders it significant, even though its object had no existence; such as a lead-pencil streak as representing a geometrical line. An *index* is a sign which would, at once, lose the character which makes it a sign if its object were removed, but would not lose that character if there were no interpretant. Such, for instance, is a piece of mould with a bullet-hole in it as sign of a shot; for without the shot there would have been no hole; but there is a hole there, whether anybody has the sense to attribute it to a shot or not. A *symbol* is a sign which would lose the character which renders it a sign if there were no interpretant. Such is any utterance of speech which signifies what it does only by virtue of its being understood to have that signification.

(2) Used for COEFFICIENT (q. v.) or MARK

(q. v.). Cf. LOCAL SIGN, and TEMPORAL SIGN. (C.S.P.)

This division of signs, suggested by C.S.P., may be compared with the more generally recognized classification given under SIGN-MAKING FUNCTION; they serve different purposes, and do not seem to be inconsistent. (J.M.B.)

Sign (and **Signature**, in psychology).

(1) See SIGN (1), and cf. LOCAL SIGN, TEMPORAL SIGN, SYMBOL, and SYMPTOM.

(2) Used also for the various symbols—written, spoken, &c.—of the LANGUAGE FUNCTION (q. v.), such as vocal sign, gesture sign, graphic sign, &c. (J.M.B.)

Sign (logical). Any symbol employed in logical writing. Cf. LOGICAL DIAGRAM, SYMBOL, and see the signs employed in the longer logical articles, e.g. LOGIC, LOGIC (exact), TERM, and SYMBOLIC LOGIC.

In regard to the use of signs for logical aggregation and multiplication, it is recommended that the traditional symbols be adhered to as follows:

(1) For aggregation, the plus sign +: something which is either *a* or *b*.

(2) For multiplication, the form *ab*: something which is at once *a* and *b*. (C.L.F., J.M.B.)

Signal (of Deprez): see LABORATORY AND APPARATUS, II (general).

Significance: see SIGNIFICS (1, c).

Signification (and **Application**, in logic): Ger. *Bedeutung*; Fr. *signification*; Ital. *significato*. See CONNOTATION (2), and DENOTATION, and cf. MEANING, SIGNIFICS, and SEMANTICS.

These are substitute terms for what are called by Mill and others connotation and denotation; for (1) the previously well-established use of connote was somewhat warped by Mill and his followers, and (2) these words may be applied to the corresponding properties of propositions as well as terms. The application of a term is the collection of objects which it refers to; of a proposition it is the instances of its holding good. The 'signification' of a term is all the qualities which are indicated by it; of a proposition it is all its different implications.

Great confusion has arisen in logic from failing to distinguish between the different sorts of signification, or connotation, of a term: thus to the question, Are proper names connotative? 'contradictory answers are given by ordinarily clear thinkers as being obviously correct,' for the reason that they have not the same thing in mind under the term connotation. It is necessary to distinguish between

(1) the indispensable signification; (2) the banal signification; (3) the informational signification; and (4) the complete signification. (1) is so much as is contained in whatever may be fixed upon as the definition of the term—all those elements of the meaning in the absence of any one of which the name would not be applied; (2) is what 'goes without saying,' what is known to every one, and (3) is what there is occasion to give utterance to: these of course vary with the different individuals to whom the proposition is given out—that oxygen is exhilarating is informational to the student of chemistry, and banal to the teacher of chemistry (but false to those who are familiar with the latest results of the science); (4) consists of all the valid predicates of the term in question. When I say, 'The one I saw yesterday was John Peter,' the indispensable signification of John Peter is simply an individual object of consciousness (usually a man, though it may be a dog, or a doll) whom it has been agreed to designate by that name; but the banal signification, to one who knows John Peter well, is very extensive.

The same characteristics apply to propositions as well as to terms: thus the complete signification (or implication) of *All x is y* is all its valid consequences, and its complete application (or range) is all those descriptions of circumstances under which it holds good—that is to say, all its sufficient antecedents. (C.L.F., C.S.P.)

A general term denotes whatever there may be which possesses the characters which it signifies; J. S. Mill uses, in place of signifies, the term connotes, a word which he or his father picked up in Ockham. But signify has been in uninterrupted use in this sense since the 12th century, when John of Salisbury spoke of 'quod fere in omnium ore celebre est, aliud scilicet esse appellativa *significant*, et aliud esse quod *nominant*. Nominantur singularia; sed universalia significantur.' Nothing can be clearer. There is no known occurrence of connote as early as this. Alexander of Hales (*Summa Theol.*, I. liii) makes *nomen connotans* the equivalent of *appellatio relativa*, and takes the relation itself as the accusative object of *connotare*, speaking of 'creator' as *connoting* the relation of creator to creature. So Aquinas, *In sentent.*, I. dist. viii. q. 1, Art. 1. Subsequently, because adjectives were looked upon as relative terms, *white* being defined as 'having whiteness,' &c., the adjective was

looked upon as connoting the abstraction, but never unless its supposed relative character was under consideration. Tataretus, for example, who wrote when the usage was fully established, will be found using such phraseology as the following: 'Nulla relativa secundum se habent contrarium, cum non sint qualitates primae, sed solum relativa secundum dici, et hoc secundum esse absolutum et significatum principale eorum et non secundum esse respectivum et connotativum.' Chauvin (1st ed.) says: 'Connotativum illud est cuius significatum non sistit in se, sed necessario ad aliud refertur, vel aliud connotat. V.g. *Rex, magister, primus.*'

It unfortunately happened, as the above quotations show, that the precise meaning recognized as proper to the word 'signify' at the time of John of Salisbury (a younger contemporary of Abelard) was never strictly observed, either before or since; and, on the contrary, the meaning tended to slip towards that of 'denote.' Yet even now the propriety of John's remark must be recognized.

A number of works were written in the middle ages *De modis significandi*, based upon Priscian (a contemporary of Boethius), who in turn followed Apollonius the bad-tempered, 'grammaticorum princeps,' who lived in the time of Hadrian and Antoninus Pius. Cf. also Thurot, *Notices et Extraits des MSS.*, xxii. Pt. II, and Duns Scotus, *Works*, Lyons ed., I. (C.S.P.)

Significs: Ger. *Bedeutungslehre*; Fr. *théorie des significations*; Ital. *teoria delle significazioni* (the foreign equivalents are suggested). (1) Significs implies a careful distinction between (a) sense or SIGNIFICATION (q. v.), (b) meaning or INTENTION (q. v.), and (c) significance or ideal WORTH (q. v.). It will be seen that the reference of the first is mainly verbal (or rather SENSAL, q. v.), of the second volitional, and of the third moral (e. g. we speak of some event 'the significance of which cannot be overrated'; it would be impossible in such a case to substitute the 'sense' or the 'meaning' of such event, without serious loss). Significs treats of the relation of the sign in the widest sense to each of these.

(2) A proposed method of mental training, aiming at the concentration of intellectual activities on that which is implicitly assumed to constitute the primary and ultimate value of every form of study: i. e. what is at present indifferently called its meaning or sense, its import or significance.

Significs affords also a means of calling attention to the backwardness of language in

comparison with other modes of human communication, and to the urgent need of stimulating thought by the creation of a general interest in the logical and practical as well as the aesthetical value of all forms of expression. And it provides a convenient general term under which to work perhaps for an international consensus, and for a natural check upon wilful waste or misuse of the existing resources of language, by bringing to bear upon it a certain deterrent of social and academic 'constraint' (cf. the Editor's Preface, viii).

Significs make practically for the detection of lurking confusion or specious assertion in directions where the discipline of formal logic would help less directly and simply. But it is suggested that this study, so far from superseding or displacing or even distracting attention from the disciplines already recognized, would rather render them more effectual because more vitally significant: more obviously related to ordinary experience and interests. It would also bring out the moral value of a greater respect for the traditions and the future of language, and would in fact, while preparing the ground for an expansion of the limits of articulate expression, tend to create a linguistic conscience which must beneficially react upon thought, thus bringing about gradually and naturally a spontaneous consensus in definition.

Much work is already being done in this direction. Significs as a science would centralize and co-ordinate, interpret, interrelate, and concentrate the efforts to bring out meanings in every form, and in so doing to classify the various applications of the signifying property clearly and distinctly.

Literature: A. SIDGWICK, *Distinction and Criticism of Beliefs*; KARL PEARSON, *Grammar of Science*; MAHAFFY, *Modern Babel*, in *Nineteenth Cent.*, November, 1896; EUCKEN, *Gesch. d. philos. Terminologie* (1879); and *Monist*, July, 1896; BRÉAL, *Essai de Sémantique*; JESPERSEN, *Progress in Language*; F. TÖNNIES, *Welby Prize Essay*, *Mind*, January and April, 1899; BACON, HOBBS, and later WHATELEY, G. CORNEWALL LEWIS, and J. S. MILL are among those who have discussed the general subject. See also E. MARTINAK, *Psychol. Untersuch. z. Bedeutungslehre* (1901). (V.W., G.F.S., J.M.B.)

Sign-making Function: (not in use in the other languages). The selection or construction of certain objects—the signs—in order that by mentally operating with these,

results may be obtained applying to other objects—the things signified. It is also called (McCosh) the symbolic function.

The possibility of this procedure depends upon the existence of an appropriate connection between the signs and what they signify. But the nature of the connection may vary so as to constitute different kinds of signs. We may distinguish (1) the demonstrative sign, (2) the discriminative sign, (3) the mnemonic sign, (4) the expressive sign, (5) the substitute or symbolic sign. Cf. SIGN.

(1) The demonstrative sign is the simplest and most primitive. It is used by animals as well as by men. It consists in some act by which one individual, who is interested in an object present to the senses, draws the attention of another individual to that object. The second individual attends primarily to the action of the first, and is thus indirectly led to attend to something else. Pointing with the finger is a typical illustration.

(2) The discriminative sign consists in some modification of an object or addition to it, made with the view of enabling us to identify and distinguish it in the future. Thus the robber who made a chalk-mark on Ali Baba's door used a discriminative sign. The house he desired to identify in the future was so like others in the neighbourhood that he feared it would be indistinguishable. But he was convinced that he could always distinguish a door with a chalk-mark on it from a door with no chalk-mark. He accordingly made a chalk-mark on Ali Baba's door. Morgiana destroyed its discriminative value by making similar marks on the neighbouring doors.

(3) The mnemonic sign is simply an aid to memory. *A* is so connected with *B* that when we think of *A* we shall probably or certainly think of *B*. Now, if *B* is something which we are in danger of forgetting, and if we attempt to obviate this risk by arranging so that the recall of *A* shall be practically certain at the proper moment, and thus call up the idea of *B* when we want it, we are using *A* as a mnemonic sign. Some people, for instance, tie a string round one of the fingers to prevent their forgetting something which they have to do. The assumption is that they will frequently notice the string round the finger, and be thereby reminded of the business which they wish to remember. The device may fail, either because they are oblivious of the string at the critical time, or because, when they do notice it, it fails to yield the required reminder

(4) The expressive sign is not merely, like the mnemonic, a means of calling up the idea of an object. It is a means of attending to the object while it is present to consciousness. When the mnemonic sign has reminded us of that which it signifies, it has no longer any function to discharge, and may be dismissed. But words and the gestures composing the language of natural signs are constituent factors of the very act of thinking of the objects which they signify. They are means of thinking of the object, as the handle of a box is a means of lifting it; and just as some things cannot be lifted without a handle, so some objects—concepts—cannot be thought of without words, or other expressive signs. See LANGUAGE FUNCTION, and cf. SPEECH.

(5) The substitute or symbolic sign is antithetically opposed in its nature to the expressive sign. The expressive sign is a means of attending to the object signified; the substitute sign is a means of dispensing with attention to the object signified. Thus in cribbage the relative position of the pegs in the cribbage board is substituted for the relative number of points won by the players. In solving a problem by algebraical methods, when we have once assigned suitable symbols to the several quantities, we need not in the actual process think of anything but these symbols, and the rules of operation applying to them. The equation might be solved by some one who did not know what problem it represented. It is only when the solution of the equation is obtained that the need arises to retranslate our symbols in terms of that which they signify. Working with logarithms is another example. (G.F.S.)

Sigwart, Heinrich Christoph Wilhelm. (1789–1844.) Born and brought up at Remmingsheim in Württemberg, he became Privatdocent in philosophy at Tübingen in 1813; professor extraordinary in 1816; and ordinary in 1818. He died at Stuttgart.

Similar (with **Similarity, Similitude**) [Lat. *similis*, like]: Ger. *ähnlich, gleichartig*; Fr. *semblable*; Ital. *similare*. See RESEMBLANCE.

Similar (in exact logic): having a common predicate of some considerable logical depth.

Similar whole: a whole of similar parts.

Term of similitude: a general name. (C.S.P.)

Similarity (consciousness of, law of): see LIKENESS (consciousness of, and law of), and RESEMBLANCE.

Similia similibus percipiuntur [Lat.]: see PERCEPTION, ad fin.

Simple [Lat. *simplex*, from *sim*, same, one, + *plicare*, to fold]: Ger. *einfach*; Fr. *simple*; Ital. *semplice*. Original or first in its nature; elementary; without parts or complication: opposed to COMPLEX (q. v.), COMPOUND (q. v.), and derived. (C.S.P.—J.M.B.)

Simple acceptance: the acceptance of a term to signify a nature abstracted from existence, as 'animal is the genus of man' (*Century Dict.*). (C.S.P.)

Simple agreement: the agreement of one thing with another; opposed to analogy or the agreement of many things with many. **Simple agreement** is either *essential* (which is identity in the sense of unity of essence) or *accidental*. Accidental simple agreement is either internal or external; the former being either equality or likeness, the latter corollation to thirds which agree.

Simple apprehension: (1) the faculty or act of apprehending without forming judgments. See APPREHENSION (2). (2) INTUITION (q. v., in philosophy).

Simple COMPARISON (q. v.): the faculty or act by which the subject and predicate of a judgment are compared (cf. *Century Dict.*). (C.S.P.—J.M.B.)

Simple concept: a concept of which no other definite concept (at any rate, no first-intentional concept) can be predicated.

Simple consequence: (1) an inference drawn from a single premise. This was the standard form of setting forth arguments in the scholastic writings of the middle ages. The suppressed major premise was called the *consequentia*. (2) An inference drawn from a single premise, from which the conclusion follows by virtue of the meaning of the middle term.

Simple CONVERSION (q. v.): the immediate inference from a proposition to another proposition differing from the former only by the interchange of subject-term and predicate-term.

Simple enumeration: a term of Francis Bacon's, by which he means mentioning a number of instances of *a*'s which are *b*'s, and thence concluding that every single *a* is a *b*, of which he well says: 'Inductio quæ procedit per enumerationem simplicem res puerilis est, et precario concludit, et periculo exponitur ab instantia contradictoria, et plerumque secundum pauciora quam par est, et ex his tantummodo quæ præsto sunt, pronunciat.' It is not in truth induction, but a singularly futile sort of presumption.

Simple enunciation: a proposition which is not resolvable into copulative or disjunctive parts. Thus, 'All men are all rational animals' is resolvable into 'Every man is a rational animal, and every rational animal is a man.' So 'Every man is a rational animal' is resolvable into 'Every man is rational, and every man is an animal.' But though perhaps every proposition of the form 'Every *S* is *P*' is composite, yet the form itself may be regarded as simple.

Simple interpretation. In this phrase, interpretation means the subject of Aristotle's *Peri hermeneias*, that is to say, a SYMBOL (q. v.). A simple interpretation is one which does not have (either expressed in words or in circumstances) one part to show what it denotes and another to show what it signifies; that is to say, it is a term or *rhema* (PREDICATE, q. v., 2).

Simple MODE (q. v., ad fin.): a term of Locke's (*Essay*, II. xii. 5); a variation of one simple idea.

Simple necessity: the necessity of that whose contradictory involves contradiction (Scotus, *Opus Oxon.*, IV. xii. 7).

Simple part: a part which has no parts in the sense in which it is itself a part.

Simple power: the same as pure power, or that passive power which belongs to 'first' MATTER (q. v., Aristotle's use).

Simple probation: a proof consisting of a single syllogism.

Simple proposition: *simple enunciation* (q. v. above). Yet all categorical propositions are sometimes so called.

Simple question: a question which asks either *whether* or *what* anything is, as contradistinguished from a complex question which asks of a thing whether or why it has a certain character.

Simple supposition: *simple acceptance* (q. v. above). Petrus Hispanus says: 'Accidentalium suppositionum alia simplex; alia personalis. Suppositio accidentalis simplex est acceptio termini communis pro re universali significata per ipsum terminum: ut cum dicitur, homo est species, animal est genus.' Ockham (*Logica*, I. lxiv) says: 'Est autem primo sciendum quod suppositio primo dividitur in suppositionem simplicem, personalem, et materialem. . . . Suppositio simplex est quando terminus supponit pro intentione animæ sed non tenetur significative. Verbi gratia, dicendo sic, homo est species, ille terminus homo supponit pro intentione animæ, quia illa intentio est species,

et tamen proprie loquendo ille terminus homo non significat illam intentionem; sed illa vox et illa intentio animae sunt tantum signa subordinata in significando.'

Simple syllogism: a SYLLOGISM (q. v.) which cannot be resolved into several syllogisms, nor contains any composite propositions.

Simple truth: that truth which pertains to the thing itself; otherwise called 'transcendental truth.' (C.S.P.)

Simplicity (in aesthetics) [Lat. *simplex*, from *sine* + *plico*, without fold]: Ger. *Einfachheit*; Fr. *simplicité*; Ital. *semplicità*. As aesthetic quality, the restriction of the number and variety of parts in an aesthetic whole, in the interest of unity and of ease of comprehension.

It excludes not only what is superfluous or exaggerated, but even elements that might have value by adding to the richness of the unity. It represents one pole (becoming in extreme form bareness or meagreness) of aesthetically pleasing form, as variety represents the other.

Literature: KÖSTLIN, *Aesthetik*, 94 f.; see also UNITY IN VARIETY. (J.H.T.)

Simplicius. Lived in the first half of the 6th century A.D. Taught by Ammonius Saccus. He himself taught at Athens, and in 529 A.D., following the edict of Justinian closing the schools of philosophy at Athens, emigrated into Persia, but returned disappointed. A Neo-Platonic thinker, and commentator on Aristotle's works.

Simulation [Lat. *simulatio*, a feigning]: Ger. *Simulation*; Fr. *simulation*; Ital. *simulazione*. (1) MAKE-BELIEVE (q. v.); see also SEMBLANCE.

(2) Conscious perception, including EQUIVOCATION (q. v.) and LIE (q. v.).

(3) In medicine: the feigning or counterfeiting of the symptoms of a disease; also called malingering.

Mental symptoms, as well as such sensory defects as colour-blindness and deafness, seem especially liable to simulation, and are often counterfeited with the object of escape from military duty, or the consequences of a crime, or again for no very obvious intent (see below). Simulation is generally detected by the overacting of the symptoms, the absence of slight accessory characteristics, and the results of special tests. Of the various insanities, mania, melancholia, and delusional insanity (paranoia) are perhaps the most susceptible to simulation, but the number of cases

of successful simulation is probably extremely small. It should be noted, however, that in many cases a true abnormal condition is present (of which, indeed, the tendency to simulate or assume the symptoms is an expression), although not the specific disease which is simulated. Cases of moral insanity, and many of the borderland cases of mental abnormality, often exhibit a tendency to assume mental disorders which are not real. In hysteria this quasi-simulation is of an allied type. Hysterical symptoms are in a literal sense real and not simulated. But, on the one hand, while they are subject to a variety of psychical influences, and thus may be said to present a form of simulation *sui generis* (see HYSTERIA), on the other hand, medical writers note that many of the symptoms exhibited in hysteria are often produced by other and true organic disturbances.

Literature: art. Simulation of Hysteria, in Tuke's Dict. of Psychol. Med.; TOMELLINI, *Delle Malattie simulate* (1877). (J.J.)

Sin (in ethics and theology) [AS. *syn*, mischief, harm]: Ger. *Sünde*; Fr. *péchê*; Ital. *peccato*. Conscious nonconformity to or transgression of an ideal standard of right or duty as revealed in conscience or the divine law, together with the tendency or disposition to such nonconformity or transgression.

Sin is to be distinguished from crime, which is a breach of civil law, and vice, which is a breach of a social requirement, the standards of which are relative. Sin can arise only in view of an ideal requirement. Therefore only God can forgive sin. In Christian theology there are the two profoundly different views of sin and its relation to the nature of man, represented by AUGUSTINIANISM (q. v.) and PELAGIANISM (q. v.); the one finding sin deeply rooted in man's nature and rendering him helpless for good, and therefore a subject of sovereign grace, the other treating it as a disturbance which does not profoundly affect man's nature or his ability to do good.

Literature: besides the works of AUGUSTINE and the Pelagians, see JULIUS MÜLLER, *Die christl. Lehre v. d. Sünde* (Eng. trans.); JONATHAN EDWARDS, *The Great Doctrine of Original Sin defended*; A. BROWN, *The Doctrine of Sin* (1881). (A.T.O.)

Sincerity [Lat. *sincerus*, from *sine*, without, + *cera*, wax]: Ger. *Aufrichtigkeit*; Fr. *sincérité*; Ital. *sincerità*. Disposition not to mislead others either positively or negatively.

Sincerity is thus wider than veracity. The sincere man aims to be truthfully understood,

whether he make positive representations or not. Honesty is often used for sincerity in this sense. Cf. VERACITY, and LIE. (J.M.B.)

Sine qua non [Lat.]. Abbreviation of *conditio sine qua non*: necessary condition. See NECESSARY AND SUFFICIENT CONDITION. (J.M.B.)

Single: see INDIVIDUAL (different topics).

Singular [Lat. *singulus*, separate; translates Gr. καθ' ἑκαστον]: Ger. (1) *einzel*, (1, 2) *individuell*; Fr. (1) *individuel*, (1, 2) *singulier*; Ital. (1) *singolo*, (2) *singolare*. (1) Applicable, as a sign, to a single individual.

(2) In mathematics: a singular place upon a continuum is a place whose properties differ from those of all other places in the vicinity, so as to constitute in one aspect a discontinuity. (C.S.P.)

Singular or Individual (in logic). A term which, during a given discussion, is not to be treated of in separate parts is a singular or individual term.

Like many expressions in logic, the signification is not absolute, but relative to the discussion in hand. Thus 'my palette' may be, upon one occasion, an indivisible object, and upon another it may be thought of as the field for many different colours. The technical definition is this: *A* is singular or individual if for every term whatever, *x*, either no *A* is *x* or else no *A* is non-*x*; in other words, there is nothing, *x*, such that *A* can be partly *x* and partly non-*x*. A proposition containing a singular term is called a 'singular proposition.' (C.L.F.)

Singularism: Ger. *Singularismus*; Fr. *singularisme* (suggested); Ital. *singularismo* (suggested). A term used (cf. Külpe, *Introd. to Philos.*, § 14) to characterize philosophic schools 'explaining or deducing all the phenomena of the universe from one principle'; opposed to pluralism. See MONISM. (J.D.)

Sinistrality: see DEXTRALITY.

Sinking Fund: see AMORTIZATION.

Situation (social): see SOCIAL STATUS.

Skin: see CUTANEOUS SENSATION, *passim*.

Skin Sensation: Ger. *Hautempfindung*; Fr. *sensation de la peau*, *sensation cutanée*; Ital. *sensazione cutanea*. See CUTANEOUS SENSATION, PAIN, PRESSURE SENSATION, TEMPERATURE SENSATION, TOUCH, and HAPTICS.

Slavery: see SERVITUDE.

Sleep [AS. *slæp*]: Ger. *Schlaf*; Fr. *sommeil*; Ital. *sonno*. A normally periodic suspension, more or less complete, of conscious processes, due to organic conditions. Cf. DREAM. (J.M.B.)

The depth of sleep was measured by Kohlschütter (*Festigkeit des Schlafes*, 1862), who found that it increased rapidly for the first hour, then became rapidly lighter, and continued light until waking. Mönninghoff and Piesbergen (*Zeitsch. f. Biol.*, 1883, 114) found a similar curve, with indication of a much shallower deepening of sleep between the fifth and sixth hours. See also Howell, 'Physiology of Sleep,' *J. of Exper. Med.*, ii. 313.

The chief cause of sleep is probably the using up of the highly organized protoplasm in the cells of the brain; during sleep this loss is made good. A secondary cause is generally stated to be accumulation of waste matter (fatigue products) in the blood. Mosso caused appearances of fatigue in a rested dog by transfusing the blood of a tired dog into its veins, but he fails to tell us whether sleep was required for recovery. Yet fatigue of the central nervous system is certainly a predisposing condition. But wakefulness sometimes persists even in conditions of extreme exhaustion, and on the other hand the mere slackening of mental activity is often sufficient to induce sleep without previous fatigue. Animals almost invariably go to sleep when accustomed sensory stimuli are withdrawn. There seems to be no doubt that sleep is essentially connected with alteration in the conditions of the blood supply of the brain. (C.F.H.—J.M.B.)

Abnormalities of sleep may occur as deficiency in amount or nature of sleep (see INSOMNIA); or as excessive tendency to sleep, known as sleep disease or narcolepsy; or as specially prolonged sleep, of which several cases are on record (see TRANCE); or, again, as SOMNAMBULISM (q.v.) or active sleep; or as artificially induced sleep (see HYPNOTISM, and PSYCHIC EFFECT OF DRUGS). The abnormal mental symptoms of sleep are considered under DREAMS (q.v.). It may be noted that mental disturbances, such as attacks of epileptic or acute frenzy, have been known to occur in sleep. (J.J.)

Experiments on the effects of artificially induced loss of sleep have been made by Patrick and Gibert on man (*Psychol. Rev.*, iii. 469), in which determinations are made of the possible length of the waking period, the organic variations induced, and the mental effects (hallucinations, &c.).

Literature: besides the papers cited, see a general résumé of theories by DE MANACÉINE, *Sleep*; its *Physiol.*, *Hygiene*, and *Psychol.* (1897); DE SANCTIS, *I Sogni* (1899); and

the citations under INSOMNIA; see also the Psychol. Index, v. 6 (successive issues, literature of 1894 ff.). (J.M.B.)

Sleeplessness: Ger. *Schlaflosigkeit*; Fr. *insomnie*; Ital. *insonnia*. See INSOMNIA, and SLEEP.

Smart, Benjamin Humphrey. (1785-1872.) An English grammarian and writer in metaphysics. He claimed to be a follower of Locke.

Smell (sensations of): see OLFACTORY SENSATIONS. An extended bibliography is by Bawden, *J. of Compar. Neurol.*, April, 1901. (J.M.B.)

Smith, Adam. (1723-90.) Born at Kirkcaldy, Scotland, he was educated there, at Glasgow University, and at Balliol College, Oxford, for the Church of England. He gave up the clerical profession, and moved in 1748 to Edinburgh, where, with Lord Kames as patron, he lectured in rhetoric and belles-lettres. Professor of logic at Glasgow, 1751; and of moral philosophy there, 1752. He accompanied the duke of Buccleuch on his travels, and studied political institutions in different countries. Lived (1766-76) in partial retirement with his mother, and wrote his great work, *The Wealth of Nations*. He was Lord Rector of Glasgow University, 1787. His contribution to ETHICAL THEORIES (q.v.) is contained in his *Theory of the Moral Sentiments*.

Smoothness: see ROUGHNESS.

Social Accommodation or Adaptation: see SOCIAL DYNAMICS, and cf. ACCOMMODATION (in biology).

Social Compact: see SOCIAL CONTRACT.

Social Consciousness: Ger. *soziales Bewusstsein*; Fr. *conscience sociale*; Ital. *coscienza sociale*. (1) The individual mind so far as it is conscious of referring to or meaning others.

The different ways in which the individual mind may refer to or mean others is one of the important problems of SOCIAL PSYCHOLOGY (q.v.). Social consciousness, however, is a more restricted thing, since it is the consciousness of meaning others. Social psychology takes cognizance of the implication of others, whether the individual is conscious of it or not. That is, there may be elements in the individual's state and in his development which are psychically immediate to him, i.e. not recognized as having social value, although to social psychology they really have. This distinction leads to the more extended meaning that follows.

(2) General or collective consciousness: consciousness so far as it has elements, dispositions, meanings, &c., common to two or more individuals. Cf. GENERAL WILL.

The first meaning is to be preferred, 'general consciousness' being available for the second.

Literature: see GENERAL WILL, and SOCIAL PSYCHOLOGY. (J.M.B.)

Social Contract: Ger. *Staatsvertrag*, *sozialer Contract*; Fr. *contrat social*; Ital. *contratto sociale*. A supposed agreement entered into by men dwelling together in one place or country to organize a state or political constitution, establish a government, submit to its authority, and obey its laws.

The theory that political society originated in a voluntary compact, or that, at least, it is maintained by agreement, and rests on the consent of the governed, is as old as the Greeks. It was taught by Epicurus (see Fouillée's review of this subject, *La Sci. Sociale Contemp.*, chap. i). In modern times we owe its elaboration chiefly to Hobbes (*Elementa Philos. de Cive*, 1642; *De Corpore Politico*, 1650; and *Leviathan*, 1651) and to Rousseau (*Le Contrat Social*, 1762). Historical students of political science, like Bluntschli and Sir Henry Sumner Maine, have been at much unnecessary pains to prove that in fact the state developed imperceptibly out of tribal life, and is at present maintained largely by force, and have assumed that history therefore discredits the social contract philosophy. This is a criticism which Rousseau in part anticipated. A patriarchal group, or a group held together by force, he said (*Le Contrat Social*, chap. i), is, if you please, an aggregation, but not an association. That is to say, Rousseau taught that a mere population is not necessarily a society, and that society comes into existence only when men begin to make voluntary agreements. This thought has been elaborated by de Greef (*Introd. à la Sociol.*), who makes contract the distinctive phenomenon of society. Spencer (*The Man versus the State*) strongly maintains not only that the doctrine of the social contract is consistent with the theory of evolution, but also that the opposite political doctrines are inconsistent with it. Cf. SOCIAL ORGANIZATION. (F.H.G.)

Social Dynamics: Ger. *soziale Dynamik*; Fr. *dynamique sociale*; Ital. *dinamica sociale*. That division of sociology or the study of that group of social problems which deals with any break up and reconstruction of the social order, with any disturbance and re-establish-

ment of the social equilibrium, or with any change in the rate or direction of social evolution; the theory of social accommodation.

(F.H.G.—J.M.B.)

This term was invented by Comte (*Cours de Philos. Positive*, 1830-42) to designate that division of his sociology which treated of the historical progress of mankind. Spencer (*Social Statics*, 1848) used it, in closer analogy to the language of mechanical physics, as a name for the study of the gradual adaptation of society and social man to their physical and organic environment. Lester F. Ward (*Dynamic Sociol.*, 1883) employed it to denote the study of those highest social processes in which intelligence and purpose intervene to supplement and complicate the unconscious processes of cosmic evolution. Cf. SOCIONOMICS, SOCIAL ORGANIZATION, SOCIAL EVOLUTION, and SOCIAL SCIENCES.

Literature: the writers cited; TARDE, *Social Laws* (Eng. trans.); BALDWIN, *Social and Eth. Interpret.*, §§ 117, 315; see also SOCIOLOGY, and SOCIAL PSYCHOLOGY.

(F.H.G.)

Social Ethics: Ger. *soziale Ethik*; Fr. *morale sociale*; Ital. *etica sociale*. (1) Moral principles in their application to social relations and situations. In this meaning, social ethics is a department of what is called applied ethics, which deals with the application of ethical rules to actual matters of conduct in all the spheres of practice.

(2) The type of ethical theory which founds morality genetically (a) upon the social life of the individual, (b) upon that of mankind, or (c) upon both.

The theories of Adam Smith and Hume illustrate (2 a), which was the main resource of empiricism in ethics before the rise of the evolution theory. The transition from this view which emphasized sympathy and custom is seen in the work of Leslie Stephen, whose 'social tissue' is a more permanent and racial thing. The evolution ethics as expounded by Spencer brought in theories of the type (2 b) based on 'race-experience.' Current empirical genetic views in ethics belong to (2 c), a certain coincidence being supposed between the course of the individual's progress under the sanctions of his social education and the evolution of mankind in morality. It is, however, not empiricism alone which may profit by the investigations of social ethics, since it may be held that evolution in the content of morality, both in the individual and in the race, is consistent with nativism of the forms of practical reason, or that the new

stages of ethical development are distinct and analysable each for itself—not reducible to, though arising out of, earlier stages. In these ways an ethical idealism may arise on the basis of a science of social ethics.

Literature: see the section (and citations) devoted to evolution theories under ETHICS, and ETHICAL THEORIES; also BIBLIOG. F, 2, n.

(J.M.B.)

Social Evolution (1) and (2) **Social Progress**: Ger. *soziale Entwicklung und sozialer Fortschritt*; Fr. *évolution sociale et progrès social*; Ital. *evoluzione e progresso sociali*. (1) Social change in so far as it depends upon the continuous operation of the principles which constitute and condition SOCIAL ORGANIZATION (q. v.). Cf. SOCIAL FORCES AND CONDITIONS. (2) Social evolution considered as determined towards some desirable goal; contrasted with social 'retrogression' and 'decay.'

(1) These definitions make social evolution the wider term; it includes any continuous movement in the social whole in which previous change persists and enters into the determination of subsequent change, apart from what is called its direction—which is predictable only in its character, as intellectual, ethical, or other, not in its social form (so Lacombe)—and from the appreciation of it from the point of view of worth.

The definition of social evolution, therefore—like that of all evolution—requires change determined by inner forces and outer conditions, and the continuation, for a longer or shorter period, of the same sort of determination. That is, the antecedents of the change must be generalizable, and reapplicable in different cases of change. The further requisite is that the sphere in which the change occurs shall be adequately marked off—the problem of the definition of what is social.

Within these requirements there are certain theories of social evolution; there are also many more which call themselves theories that do not fulfil these conditions.

(a) Physical theories, which hold that geographical and other physical conditions are the sole or principal determining factors in social change. (b) Biological theories, which find in society an organism subject to the laws of biological evolution: variation, natural selection, heredity, &c. These two theories are 'socioeconomic.' See SOCIONOMIC FORCES. (c) Psychological theories, which consider the determination of social change

SOCIAL EVOLUTION AND SOCIAL PROGRESS

to be in some form mainly psychological, reflecting changes in the minds of the persons organized in society. (d) *Sui generis* theories, which hold that there are in social organization certain immanent and peculiar principles of determination in accordance with which all its continuous changes occur; such theories we may call 'autonomic' (see HISTORY).

The problem is extraordinarily complicated, seeing that social evolution carries with it both biological and mental evolution, and the question is mainly the demarcation of a smaller group of changes within these larger groups. The distinction between 'social forces,' on the one hand, and 'extra-social conditions,' on the other hand, has been suggested in the interests of a solution (see FORCE AND CONDITION). The 'social forces' proper are intrinsic sources of change—within the order of phenomena itself—changes which precede other social changes and so determine the latter; 'extra-social conditions' are the phenomena in the larger spheres, physical, biological, psychological, which condition the special social changes as such. The same distinction is required in other departments of science; for example, the chemical changes occurring in living tissues, while not themselves considered vital, are nevertheless 'extra-vital conditions,' so to speak, of the determination of vital change and function. So geographical separation or 'isolation' conditions biological change by limiting mating, but it cannot itself be called a biological principle. See SOCIOECONOMIC FORCES.

The general principle of RECAPITULATION (q. v.) has been borrowed from biology and applied analogically by Lilienfeld; and Baldwin has used the corresponding principle of psychological recapitulation. Others have pointed out the profound significance of social life as a determining or orthoplastic factor in biological evolution. Cf. ORGANIC SELECTION (5, 6).

(2) Besides the distinction made in the definitions given above, social progress differs from social evolution in a way which the distinction between social forces and extra-social conditions serves to make more plain. Social progress is not only in a desirable direction, whatever 'desirable' in a particular case may mean, but it is necessarily always the same—once fully described, always described—inasmuch as it states the essential action of forces intrinsically and immanently social. But social evolution is liable to many different statements, in different social groups, in succession or simultaneously; that is, it

includes the extra-social conditions, with the limitations, intrusions, hinderings, helpings, &c., which they bring, to the working out of the social forces properly so called. We accordingly find here, as in biology, a distinction between what Romanes calls the 'monotypic' and the 'polytypic.' Social progress is monotypic; it depends upon the strictly social, and is in one direction always. Social evolution is polytypic; it expresses the social growth when hemmed and conditioned by physical, biological, and psychological situations and events, and is in many diverging directions. (J.M.B., G.F.S.)

Various theories as to what constitutes social progress are current: physical comfort, material wellbeing, intellectual and moral culture, psychological integration in a recognized whole of rights and duties, civilization (itself liable to equal variations of definition)—all these are advocated. The early socialistic leaders, Saint-Simon and Fourier, and the Radical pamphleteers like William Godwin, conceived of progress as a movement that could not stop short of the perfect political and economic emancipation of the working classes and their intellectual enlightenment. Comte's conception of progress included the growth of positive knowledge and of altruism, but placed the emphasis on the substitution of positivism for theology and metaphysics, resting this on the view that 'society progresses only by ideas' (Barth, as below, i. 30). According to Lacombe the goal is intellectual accumulation and moral 'conciliation.'

Herbert Spencer places emphasis on sympathy and altruism, the social nature, rather than on increasing knowledge, and upon the decay of militarism as an essential condition. Mackenzie (*An Introd. to Social Philos.*) lays stress on (1) material wellbeing, (2) improvement in social organization, (3) improvement in the mental and moral nature of man. (J.M.B.—F.H.G.)

The concept of SOCIAL RETROGRESSION AND DECAY (q. v.) goes with that of social progress, and is liable to the same alternatives of definition.

Literature (in which social evolution and social progress are usually used interchangeably): besides the discussions given in the works cited under SOCIOLOGY and SOCIAL PSYCHOLOGY, see STEPHEN, *Sci. of Eth.*; ALEXANDER, *Moral Order and Progress*; MALLOCK, *Aristocracy and Evolution*; NOVICOW, *Conscience et Volonté sociales*; TARDE, *La*

Logique sociale; LE BON, *The Psychol. of Peoples* (Eng. trans.); MACKENZIE, *Introd. to Social Philos.*; FEDERICI, *Le leggi del progresso* (1885); BARTH, *Geschichtspphilos. als Soziol.*, i; LACOMBE, *La Sci. de l'Hist.*; BALDWIN, *Social and Eth. Interpret.* (3rd ed.). See also BIOLOGICAL ANALOGY, and IMITATION. (J.M.B.—E.M.)

Social Force: Ger. *soziale Kraft*; Fr. *force sociale*; Ital. *forza sociale*. The ground of social change so far as it is internal or intrinsic to the social organization in which the change occurs. Cf. FORCE (various topics).

The common confusion between force and energy should be avoided here. In the words of the author of the article on another topic—ENERGY (q. v.)—‘Spencer’s exposition of the subject is defective through trying to extend the conception of energy into fields where no transformation of mechanical energy into the concepts of the field is possible.’ Energy is amount of change produced measured in terms of exact units. For social change there are no exact units of measurement, and it is impossible to bring over physical units into this field. To illustrate what social energy would be, suppose we assume that one act of imitation by one individual of another is the unit of quantity or mass (m), then in a given case of propagation of an idea in society we would have the kinetic social energy of a series of changes $KE = \frac{mv^2}{2}$, where m is one imita-

tion and v is the rapidity with which such imitations occur—a grotesque aping of physics. (J.M.B., G.F.S.)

A point of great importance in the history of the term is the differentiation of the conception of social force from that of forces that create society. The term has long been inaccurately used to designate the latter. Comte so used it, and the usage was followed by Spencer, Ward, de Greef, Patten, and others. Cf. FORCE AND CONDITION, and SOCIONOMIC FORCES. (F.H.G., J.M.B.)

Social Heredity: see HEREDITY (2), and TRADITION (in biology).

Social Logic: Ger. *soziale Logik*; Fr. *logique sociale*; Ital. *logica sociale*. The form of SOCIAL PROCESS (q. v.) considered as analogous to the form of union of premises in a logical conclusion.

The terms social logic (Tarde, *La Logique sociale*) and ‘mental energy’ (Wundt) are used in connection with ways of looking at social evolution more or less analogically. The former considers social organization as

analogous with the form of syllogistic reasoning; the latter considers it under analogy with physical energy—a so-called ‘law of increase of mental energy’ being true of social evolution, while in physics there is conservation of energy. As to the latter view, the remarks made under SOCIAL FORCE would seem to be applicable; the conception of energy has no legitimate application. (J.M.B.)

Social Opposition: Ger. *soziale Opposition* (or *Streit*); Fr. *opposition sociale*; Ital. *opposizione sociale*. Interference or conflict in the operation of SOCIAL FORCES (q. v.): as in COMPETITION, RIVALRY (q. v.), oppression, revolt, &c., considered as involving social forces (cf. Tarde, *Social Laws*, Eng. trans., *Opposition universelle*, and *Psychologie économique*, 1901). (J.M.B.)

Social Organism: Ger. *sozialer Organismus*; Fr. *organisme social*; Ital. *organismo sociale*. The organized body of society considered under the analogy of the physiological or biological organism. See BIOLOGICAL ANALOGY.

Both the utility and the exact meaning of this analogy are much discussed. The tendency of those who consider society an organism is to depart from the strict biological conception of organism and to give the term a larger meaning. Cf. ORGANISM, and ORGANIZATION.

Literature: see the references under SOCIOLOGY, and BIOLOGICAL ANALOGY. (J.M.B.)

Social Organization: Ger. *soziale Organisation*; Fr. *organisation sociale*; Ital. *organizzazione sociale*. That relation among individuals established, at least in part, by their use of their minds and through their intercourse, and sufficiently stable and progressive to be called an ORGANIZATION (q. v.); also the process of the rise of such relationships.

The problem of social organization as a genetic and comparative question belongs to general SOCIOLOGY (q. v.); its investigation under various phases and by different methods belongs to the special SOCIAL SCIENCES (q. v.). As a matter belonging to sociology, two great questions may be separately treated, although it is only by abstraction that this separation is effected: (1) the problem of social matter—what is the matter organized?—and (2) how is this matter organized?—by what method or process?

In answer to the first of these questions, various sorts of matter are held to be intrinsic to social organization: individuals, as such, minds and bodies; minds of any order; minds of a relatively high order; thoughts; beliefs;

desires; volitions; feelings; the social self or socius; whatever is imitable; various combinations of these.

In answer to the question of social method or process, we are told: natural selection; laws of physiological organization and growth; social contract; personal growth as implicating a social group; imitation; constraint and obedience. These are also variously combined.

The philosophy of social organization requires the solutions of these two questions combined in one general principle. The matter which enters into the organization must assume the form of the organization by itself exhibiting the process or method. In other words, it is not possible—as was said above—except by abstraction, to conceive a sort of matter brought into organization by laws or processes which are not *its* processes. The true social forces of change are intrinsic and not imposed. See SOCIONOMIC FORCES, and cf. FORCE AND CONDITION. It is necessary to emphasize this; for when we come to put the test upon various social theories in which answers to the two questions are more or less confusedly given, it is found that matter and process have determinations which forbid their union save in a logical or in a mechanical way.

There is a distinct tendency to accept the view that the matter is psychological—whether thought (Comte, Hegel, Lacombe, Fouillée, Baldwin) in whole or in large part, beliefs and desires (Tarde), or feelings and actions. This has the advantage of allowing the principle of imitation to play as the method or process involved—the questions remaining over (1) as to whether imitation is the whole of the method (Tarde), or an incident of a larger process, such as personal growth (Baldwin); and (2) as to the mental content of the development of which imitation is an intrinsic mode.

Social organization is progressive (cf. SOCIAL EVOLUTION AND SOCIAL PROGRESS), and the principles established in the theory must have here their further play. It is generally recognized that what is called invention supplies the new elements incorporated in social growth; these taken up by imitation become available as social material (so with various modifications, Taine, Lacombe, Tarde, L. Morgan, and the present writer).

Literature: that of SOCIOLOGY, SOCIUS, and STATE (philosophy of); an expository work arranged by schools and individuals is BARTH, *Geschichtsphilos. als Soziol.*, i; see also the various topics SOCIAL. (J.M.B., F.H.G.)

Social Philosophy: Ger. *soziale Philosophie*; Fr. *philosophie sociale*; Ital. *filosofia sociale*. Study of the social sciences considered as a department of philosophy; that is, as contributing data to the synthesis of knowledge which philosophy attempts to make. Cf. PHILOSOPHY, SOCIOLOGY, STATE (philosophy of), and SOCIAL SCIENCES. (J.M.B.)

Social Process: Ger. *sozialer Prozess*; Fr. *processus social*; Ital. *processo sociale*. The form of continuous change which the material of social organization undergoes; that process which, when true of a peculiar sort of facts, constitutes social phenomena. Cf. SOCIAL ORGANIZATION. (J.M.B., F.H.G.)

Social Progress: see SOCIAL EVOLUTION.

Social Psychology: Ger. *soziale Psychologie*; Fr. *psychologie sociale*; Ital. *psicologia sociale*. That department of psychology which treats of the individual mind with reference to the implication of other minds in its functions and development.

Social psychology is, on this definition, a more or less arbitrary division of general psychology; its material being taken from the larger body of data, and its problem being to find what is capable, on adequate analysis, of being so treated. This is, however, only one of the current definitions; the scope of social psychology is much discussed in relation to SOCIOLOGY (q. v.) and ETHICS (q. v.).

Literature: works on SOCIOLOGY (q. v.); G. TOSTI, *Social Psychol. and Sociol.*, in *Psychol. Rev.*, v. (1898) 347 ff.; WORMS, *Psychologie individuelle et collective*, *Rev. Int. de Sociol.* (Jan., 1899); BALDWIN, *Social and Eth. Interpret.* (3rd ed., 1902); TARDE, *Études de Psychol. sociale*; L'Opinion et la Foule (1901); and La Psychol. économique (1901); SIGHELE, *La Foule criminelle* (Fr. trans., 2nd ed., 1900); P. ROSSI, *Psicol. collettiva* (1901). (J.M.B., G.F.S.)

Social Retrogression (and Decay): Ger. *sozialer Rückschritt (und Verfall)*; Fr. *rétrogression (et décadence) sociale*; Ital. *regresso (e decadenza) sociale*. The undoing of the results of social evolution.

It seems to involve (1) a diminution of social welfare (see SOCIOLOGY); (2) a return from liberal to absolute forms of social organization; (3) a breaking up of compound nations into their component societies; (4) a degeneration of the social nature of individuals; and (5) a dispersion of population.

Social retrogression may begin at any stage in social evolution, in tribal society, or in civilization. The ancients recognized the

SOCIAL SCIENCES

facts of social retrogression, and the phenomena have never since been more vividly and accurately described than by the Old Testament Prophets.

(F.H.G.)

It is often held, and there is much to be said for it, that social retrogression and decay involve, as does social evolution, ethical disintegration, and, further, that this is the essential fact. Whether this latter statement is true would seem to depend upon what is held as to the nature of social progress. If we find that the fundamental fact, the *sine qua non* of social organization and advance—that which is common to all special forms of social wellbeing and of institutional life—is ethical, then social retrogression is not present unless there be ethical degeneration in individuals. Such a fundamental thing as justice may be interpreted ethically. This question is, however, left open in the point indicated above (4).

The word decay is stronger than retro-

gression, and seems to apply primarily to the disintegrating process in individuals.

Literature: SCHÄFFLE, *Struct. u. Bau des sozial. Lebens*; BARTH, *Philos. d. Gesch. als Soziol.*, i, in loc. (J.M.B.)

Social Sciences: Ger. *soziale Wissenschaften*; Fr. *sciences sociales*; Ital. *scienze sociali*. The group of sciences which deal with social AGGREGATION (q. v.).

The following table presents the main sciences of society, SOCIOLOGY (q. v.) proper being contrasted as general with the special departments of research, after a somewhat analogous development to that which the BIOLOGICAL SCIENCES (q. v.) have pursued. Cf. also SOCIONOMIC FORCES, SOCIAL ETHICS, SOCIAL ORGANIZATION, and SOCIAL PSYCHOLOGY.

Giddings (*Princ. of Sociol.*) puts the analytic and descriptive problems first and the historical second, and includes both under 'General Sociology' (q. v., from which certain of the headings are taken).

(J.M.B.)

(J.M.B.)

Social (1) Selection and (2) Suppression: Ger. *soziale Auswahl und Unterdrückung*; Fr. *sélection et suppression sociales*; Ital. *selezione ed eliminazione sociali*. (1) Conscious selection of one individual by another considered as a factor in social or biological evolution. Cf. SELECTION (in biology, and in psychology).

(2) The social selection of an individual for exclusion from social life: social elimination.

Social selection is illustrated well in matrimony—say, the marriage of a white man to a negro woman in New York—since the result is influential biologically as well as socially: socially, because the children are trained by a woman of low culture and are socially ostracized (social heredity); and biologically, because their strain of negro blood, by shutting them up to negro marriages (except in very rare instances), is continued and strengthened in later generations (physical heredity). This latter point is referred to elsewhere (see SOCIONOMIC FORCES, 3).

The influence of social selection on biological evolution has been recognized in many ways in recent discussion. Wallace calls it 'selective association' in cases in which it brings together groups of animals and practically isolates them for interbreeding (cf. Gulick, *Nature*, April 1, 1897). See ISOLATION. Wallace's RECOGNITION MARKS (q. v.) are also a means of this sort of selection.

Social suppression is illustrated in all measures, either conventional and purely voluntary, as in the isolation of a person shunned by others, or legal and compulsory, as in the imprisonment or hanging of a criminal. Such persons are also physically eliminated, since they are not allowed to have offspring. (J.M.B., C.L.M., F.H.G.)

Among animals social selection, though influential in determining the course of evolution, is not purposeful; that is to say, the animal does not select with the aim of determining the course of evolution in some specific way. In man social selection may rise to this higher level; and choice may be exercised with the distinctly conceived object of attaining a given social end.

Literature: see SELECTION (in biology), and SOCIAL PSYCHOLOGY. (C.L.M., J.M.B.)

Social Statics: Ger. *soziale Statistik*; Fr. *statique sociale*; Ital. *statica sociale*. That division of sociology, or the study of that group of social problems, which deal with a stable social order, with social forces in equilibrium,

with social evolution that does not change in rate, form, or direction.

This term, like SOCIAL DYNAMICS (q. v.), was invented by Comte to designate that division of his sociology which treated of a stable social order and of coexistent social phenomena in distinction from all phenomena of sequence. Spencer, in *Social Statics*, used it to denote a study of social equilibrium, which, according to his reasoning, exists when the interests, motives, and activities of the individual members of society are in balance. This, he held, is attained when every man has perfect liberty to do all that he wills so long as he does not trench on the equal liberty of any other. Cf. SOCIAL SCIENCES. (F.H.G.)

Social Status: for foreign equivalents of STATUS, see that term. The position in society which an individual member, family, community, or class occupies by reason of birth, social tradition, or achievements.

An individual may improve his social status, but only by influencing the minds of his fellow men. The final determination of his social rank, position, or reputation is by a combination of historical and psychological factors objective to himself.

The conception is older than recorded history. In primitive as in the most advanced societies the community recognizes that the individual is for all practical purposes only what his position in the community allows of his being. Cf. CASTE. (F.H.G.)

The idea of social status has been recast in recent discussion, in which social organization has been interpreted as being, in any case, a 'situation' in which the status of each member is reflected more or less adequately in the individual's consciousness of the situation as a whole including himself. Bosanquet (*Philos. Theory of the State*) interprets the fundamental conceptions of social philosophy as relative functions of such a psychological status; e.g. the individual's consciousness of justice and right is a function of his thought of the social situation as involving a series of individuals, each, including himself, having a relative status. The present writer (*Social and Eth. Interpret.*) reaches what he calls a 'self-thought situation,' meaning the individual's thought of the actual social situation as an organization of selves, including himself, having status relatively to one another. (J.M.B.)

Social Suppression or Elimination: see SOCIAL SELECTION AND SUPPRESSION.

Social Theory: see SOCIAL SCIENCES, and SOCIOLOGY.

Social Tissue: Ger. *soziales Gewebe*; Fr. *tissu social* (not used—L.M.); Ital. *tessuto sociale*. (1) Those individual members of society who, collectively regarded, are fitted by heredity and habit for normal social life. More specifically, individual members of society who by heredity and habit (mental and moral) are adapted to a particular situation, station, or function in normal society.

The term is employed in the meanings given in the foregoing definitions by Leslie Stephen (*Sci. of Eth.*), but the conception is Platonic, being fully worked out in Plato's *Republic*. (F.H.G.)

(2) Used in connection with the analogy between society and a biological organism to indicate the particular 'tissue'—bone, muscle, &c.—to which this or that group of social phenomena corresponds (Schäffle).

Simiand playfully suggests that the rich are society's 'adipose tissue,' and that the 'priests also represent fat.' (J.M.B.)

Social Unit: Ger. *soziale Einheit*; Fr. *unité sociale*; Ital. *unità sociale*. The irreducible element of social organization; that which includes what is essential to the social as such, and nothing more.

Attempts to determine the social unit have been embarrassed by the varying conceptions of social organization and of social evolution. Atomistic theories of society find a unit which by compounding produces the varied phenomena of social life. So the individual has been treated as the unit, which is in some way brought into combination with others. It is true that the individual is the unit of the social GROUP (q. v.); but he is not the social unit, since the social is a relation of individuals. So others say the social group as such is the unit (see Gumpłowicz, *Sociol. und Politik*, 37, 53).

The biological theorists look for a unit analogous to the physiological cell, and attribute to it various 'functions' in the economy of the social organism. The psychological school find the unit in the psychological state which is in some way both individual and common to two or more individuals, so that by its possession a social relation is constituted between or among the individuals. Various constructions have been put upon this, the least requisite psychological state considered as, wherever present, *ipso facto* constituting a social situation. The questions of its origin, development,

embodiment, variations, &c., are problems of the different SOCIAL SCIENCES (q. v.).

The conception of unit here, as in psychology, is very misleading, since it is only by an abstraction that any social phenomenon can be considered a unit of quantity for treatment. In all such cases the unit is an arbitrary determination. In MORAL STATISTICS (q. v.) the unit is one case of the phenomenon in question (suicide, theft, &c.). There is no general social unit, and it is doubtful whether in the social sciences any final unit of analysis will ever be discovered in terms of which all phenomena of the class can be quantitatively expressed. The attempt to treat psychology by the theory of COMPOSITION (q. v.) of units has not succeeded. The phrase 'fundamental social fact' used in recent literature better expresses the scope of the inquiry in this field.

Literature: see SOCIOLOGY, and SOCIAL PSYCHOLOGY. (J.M.B.)

Socialism: Ger. *Sozialismus*; Fr. *socialisme*; Ital. *socialismo*. (1) The disposition to rely on political activity, rather than on individual liberty, as a means of securing the people's material welfare.

(2) Specifically applied to certain historic manifestations of this disposition—literary, administrative, or revolutionary.

The word socialism dates from about 1835, and seems to have originated in several quarters simultaneously. Leroux claims to have invented it as an antithesis to individualism. The development of the doctrines of political economy and of civil liberty had led many people to see in enlightened self-interest a panacea for social ills. Socialism was a protest against this view.

Now individualism is not a creed or a platform, but a way of looking at things; and the same thing may be said of socialism, in the first and broader sense. Under these circumstances we cannot expect to find, and do not find, a coherent statement of socialistic doctrine, generally accepted by socialists as a body. A man may easily be a socialist in some senses and an individualist in others. The individualist is the man who in a number of debatable cases believes that the good from freedom outweighs the evil. The socialist is the man who in these same cases believes that the evil outweighs the good. The difference between the two is in many cases a matter of temperament. The man who reasons more acutely than he feels is pretty certain to be an individualist; the man who feels

more acutely than he reasons is likely to be a socialist. For the good of freedom is essentially an indirect one, only to be fully understood by those who are capable of abstract reasoning, and likely to be exaggerated by those who overvalue such reasoning.

But most of the men who are inclined towards socialistic views fall into certain pretty well defined groups; and the name socialism is applied by turns to the creed and platform of each of these groups. It thus acquires in practice a number of specific senses in place of one general sense. The three main groups of socialists are the *administrative*, the *idealistic*, and the *revolutionary*.

The administrative socialist is the man who believes in extending the authority of the existing state, with such modifications as may fit it to its wider sphere of activity. He would give more rights to the officials and less freedom to the individual property-owner. He would regulate the hours and conditions of labour; would provide for factory inspection; would substitute compulsory saving in its various forms (pensions) for voluntary saving; would have state management of means of transportation and other industrial monopolies; would generally favour progressive taxation, inheritance taxes, and other measures designed to put larger proportionate burdens on the rich; and would in many cases look favourably upon strict regulation, if not actual nationalization, of landed property. The administrative socialists are sometimes divided into two sub-heads: the state socialists proper, who go into these measures as a matter of practical politics, and the professorial socialists (*Kathedersozialisten*, *Socialistes en chaire*), who adopt them as a result of disinterested study. The most advanced form of administrative as distinct from revolutionary socialism is perhaps represented by the English 'Fabian Society.'

The idealistic socialist is apt to be by temperament an artist—a man who feels so keenly the evils of the present system that he is blind to the impracticability of his proposals. He may occupy himself with devising Utopias, like Plato, or More, or Bellamy; or he may appear to stand on more solid ground, like Carlyle or George, and achieve great literary success by that combination of keen perception of present evils with inadequate analysis of the difficulties in the way of reform which

appeals so strongly to the sentiment of the reader. Or he may use similar appeals as a means of strengthening the religious feeling and religious organization of the community—a thing often attempted, and sometimes successfully, by Christian socialists, both Catholic and Protestant. The sentiments thus awakened, whether aesthetic or religious, may result in the establishment of socialistic experiments like those of the disciples of Robert Owen, the Brook Farm, or the religious co-operative societies like the 'Shakers'—communistic organizations in the strictest sense of the word, yet absolutely foreign, in their purposes and methods, to the ideas of the Communist League. It is in the nature of things impossible to formulate or classify the proposals of idealistic socialism; its advocates unite only in their condemnation of the present economic organization of human society and their belief in the automatic improvement of human nature when this weight is removed.

The revolutionary socialist feels the evils suggested by the idealist, but does not share his sanguine hopes. He agrees, in general, that the practical reforms suggested by the administrative socialist are desirable, but he thinks that such reforms, if carried out by the officials of governments as they now exist, would only substitute one form of tyranny for another. He overestimates the power of the machinery of government, and believes that if this machinery can really be brought into the hands of the masses all will go well. This idea, well expressed by Rousseau, is the central article in the revolutionary socialist's creed. He is a social democrat—democrat first and socialist afterwards. He is occupied at once with attacking the power of capital (which he thinks Marx has proved to be wholly unnecessary) and the power of governmental aristocracy. For this end he is ready to adopt either constitutional or extra-constitutional means; to join hands with the Fabian or with the Nihilist, as may suit his purpose; to take part with equal readiness in the trades union congress, the parliamentary debate, or the appeal to force. His economic proposals as embodied in the manifestoes of the Communist League or the International have a superficial resemblance to those of the administrative socialists. But fundamentally they are based upon a different idea—the idea that capital is not a power whose abuses are to be checked, but a usurper which consists of nothing but abuses. Considering all value

to be based on labour, he regards capital as being in its origin property withheld from the labourer, and in its continuance a means of withholding further property every year. Constitutional law, as at present administered, he thinks to be nothing better than a means of using the organized forces of society to perpetuate this species of robbery.

It should be said in justice to the great body of revolutionary socialists that these extreme positions have been in a measure forced upon them by the continental governments, whose policy of repression has made it impossible for the moderate socialists among the labouring classes to have a fair chance either outside of Parliament or within it.

Literature: perhaps the best general work on socialism for the English reader is RAE, *Contemp. Socialism* (2nd ed., 1891). See also MARX, *Das Kapital* (3 vols., 1867, 1885, 1894); SCHÄFFLE, *Die Quintessenz des Socialismus* (1875); LEROY BEAULIEU, *Le Collectivisme* (1884); and *Fabian Essays in Socialism* (ed. by Shaw, 1890); RUSSELL, *German Social Democracy* (1896). (A.T.H.)

Sociality or Sociability: Ger. *Geselligkeit, Gesellschaftlichkeit*; Fr. *sociabilité*; Ital. *società* (or *sociabilità*). Disposition towards intercourse with one's fellows. Cf. DISPOSITION. Not a technical word. (J.M.B.)

Socialization: Ger. *Sozialisierung*; Fr. *croissance de sociabilité, socialisation*; Ital. *sviluppo della socialità*. The accommodation of individuals to one another and to a social life. See CONSCIOUSNESS OF KIND, SOCIUS, SOCIOLOGY, SOCIAL CONTRACT, and STATE OF NATURE.

Socialization is accomplished through migration, communication, acquaintance, imitation, the formation of common judgments, co-operation, and common pleasures; the question being left open as to the psychological fact or process which makes them effective. (F.H.G.—J.M.B.)

In the savage state, socialization is almost wholly bounded by kinship, and it is a product chiefly of common pleasures of a rude kind, e.g. the Australian corroboree. In the barbarism of pastoral and nomadic life, socialization is intensified rather than extended. Only when a settled agriculture, and the beginnings of trade, bring together in one community men of varied ancestral experiences, of different tribal origins, does socialization begin on a large scale through a wide

extension of acquaintance. It is then, too, that the subordination of rank to rank, of class to class, begins, a process which Simmel and Gumpowicz have regarded as practically identical with socialization—a view which, however, can hardly be defended. Cf. the literature of SOCIOLOGY. (F.H.G.)

Societas leonina [Lat.]. A partnership in which it is agreed that one of the partners shall have all the gains, while the others are liable for the losses.

This term is that used by the Romans, by whose law such a partnership was prohibited. 'Iniquissimum enim genus societatis est, ex qua quis damnum, non etiam lucrum spectet' (*Dig.*, xvii. 2, *pro Socio*, 29, § 2). The French *Code Civil* also forbids such a contract (art. 1855). It would probably be legal by Anglo-American law, the policy of which is to promote freedom of contract (see PARSONS, *Princ. of Partnership*, § 48). (S.E.B.)

Society [Lat. *societas*]: Ger. (5) *Gesellschaft*; Fr. (5) *société*; Ital. (5) *società*. (1) A biological COLONY (q.v., meaning 2), for which this latter term is preferable.

(2) Any social GROUP (q.v.), for which this latter term is preferable.

(3) A commercial, scientific, or other organization for a special purpose. Cf. COMPANY (meaning 2).

(4) The public, others; as in the expressions 'the opinion of society,' 'to be in society.' Not technical. (J.M.B.)

(5) A social group characterized by some degree of reflective and voluntary CO-OPERATION (q.v.). 'A number of like-minded individuals who know and enjoy their like-mindedness and are therefore able to work together for common ends' (Giddings, *Elements of Sociol.*). (J.M.B.—F.H.G.)

(6) A naturally formed population occupying a defined territory (e.g. England, France, or the United States), of which, on the whole, definition (5) is true.

In the history of the concept of society, three questions of philosophical importance have arisen, namely:—

(1) That of the essential nature of society (for the history of this question see SOCIOLOGY); (2) that of the distinction between natural and political society; and (3) that of the inclusion of animal groups under the term societies. The distinction between natural and political societies was imperfectly made by Hobbes and Locke, and precisely made by Bentham (*Fragment on Government*, chap. i). Cf. STATE (philosophy of).

Evolutionary studies have carried the investigation of social origins back to animal life, e.g. the writings of Espinas (*Des sociétés animales*). Baldwin (*Social and Eth. Interpret.*) proposed the restriction of the word society as in definition (5), and the use of COMPANY (q. v.) for animal and human groupings and activities that are instinctive, unreflective, and unprogressive (so also in substance Comte; cf. Barth, *Geschichtsplilos. als Soziol.*, i. 32).

(F.H.G.)

Socinians: Ger. *Socinianer*; Fr. *Sociniens*; Ital. *Sociniani*. The historical designation of the followers of Laelius and Faustus Socinus, who in their doctrinal beliefs combine a unitarian conception of the divine nature with what is known as the moral theory of the Atonement and the assertion of man's power and free initiative in the matter of his own salvation.

Socinianism originated in Italy in the 16th century, and is the forerunner of modern unitarianism. It differs from Arminianism in its theory of the Atonement and in its denial of the divinity of Christ. It is not, however, to be identified with a purely humanistic view of Christ, inasmuch as it ascribes to him quasi-divine attributes and regards him as a legitimate object of worship. The term, however, covers considerable variation of opinion.

Literature: TOULMAN, *Life of Socinus*; HARNBECK, *Socinianismi Confutatio* (1664); DORNER, *Hist. of the Person of Christ*, II. ii; CUNNINGHAM, *Hist. of Theol.*, ii; TOCCO, *L'Eresia nel Medio Evo.* (A.T.O.)

Sociology [Lat. *socius*, a companion, + Gr. *λόγος*, science]: Ger. *Soziologie*; Fr. *sociologie*; Ital. *sociologia*. (1) The genetic and comparative study of social groups; that is, the study of the origin and relationships of social groups as such.

Sociology is thus a general social science, as contrasted with the special social sciences, which deal with the composition, elements, and internal organization of social groups. Cf. SOCIAL SCIENCES, and STATE (philosophy of).

(2) The scientific study of society, including all the special SOCIAL SCIENCES (q. v.).

(J.M.B., G.T., F.H.G.)

Comte, in 1838, first used the word '*sociologie*' as a name for a division of the *Cours de Philosophie positive*, and, notwithstanding many protests against it as a barbarism, it has held its own in both scientific and popular usage. Komology (from *κώμη*, a community,

a throng, a rout) would have been a better term for the scientific description of organized communities (cf. Barth, *Geschichtsplilos. als Soziol.*, i. 28). The publication in 1873 of Spencer's *Study of Sociology* established both the word and the study in popular favour, and within the next fifteen years no less than four great expositions of sociological knowledge were before the public, namely, Spencer's *Descriptive Sociology* and *Principles of Sociology*, Schäffle's *Baru und Leben des socialen Körpers*, Ward's *Dynamic Sociology*, and de Greef's *Introduction à la Sociologie*.

Comte and Spencer both worked out their systems of sociology as divisions of a cosmic philosophy, rather than as special fields of investigation. Comte's chief purpose was to demonstrate that society could be studied by positive methods, from which theological dogmas, metaphysical assumptions, and revolutionary purposes should all be eliminated. Incomplete as his work was, Comte undoubtedly prepared the minds of educated men for a different way of looking at social order and progress from that which had before prevailed. Actually the scientific study of society by both inductive and deductive methods had been soundly established by Aristotle in the *Ethics*, the monographs on Greek constitutions, and the *Politics*; by Machiavelli, Hobbes, and Locke, in their analyses of political motives; by Grotius and Montesquieu, in the historical study of law and civilization; and by Adam Smith, by both deductive and historical methods, in *The Moral Sentiments* and *The Wealth of Nations*. In none of these works, however, save Aristotle's, were social phenomena dealt with in their completeness, and in none, not even in Aristotle's, was social science clearly discriminated from politics. Comte first pointed out these limitations, and aimed to show what field sociology must cover and to what scientific requirements its methods must conform.

Spencer gave an entirely new and modern character to social philosophy by arguing that all social changes, like all changes in organic nature, must be interpreted in terms of the universal processes of evolution. Social organization, like the organization of cells in the plant or animal body, exhibits the stages of integration and differentiation, and all its phenomena are conditioned by the equilibration of energy between the organized group and its surroundings or environment. The adaptation of the social system and of the

individual units that compose it to their environment is, according to Spencer's views, just as certainly the determining factor in all lesser social changes as is the adjustment of the organism to its environment in all minor physiological changes. In society, however, the important phenomena are psychological rather than physiological, and Spencer emphasizes two psychological principles (both regarded by him as phases of the adaptation of mankind to the conditions of life) as of chief importance in the history of civilization. One of these is, that while fear of the living becomes the root of all political control, fear of the dead becomes the root of all ecclesiastical control. The other is, that habitual militarism and habitual industrialism give rise to opposite types of character, morality, law, government, and social organization. In working out the details of this system, Spencer made extensive use of anthropological and ethnological data. His scheme thus presents three of the four or more possible modes of investigation of social phenomena, namely, the biological or organic, the psychological, and the ethnological. The statistical, first exploited by Quetelet (*Du Système social et des Lois qui le régissent*, 1848), is not much employed by Spencer.

Later work in sociology has emphasized one or other of these methods, and a tendency has appeared among sociologists to group themselves in schools. One of these, starting from such parts of Spencer's work as his essay on 'The Social Organism' (*Westm. Rev.*, 1860), and following the example set by Schäffle in the *Bau und Leben*, is strongly represented at the present time in France, and especially in the writings of René Worms. It holds that society is in reality, and not merely in analogy or figuratively, an organism, and that practical social reform awaits the development of a social pathology founded upon a sound knowledge of social anatomy and physiology. By sociologists of other schools all this is regarded as fanciful and of little scientific or practical value. The ethnological school is represented in France by Letourneau, whose ten or more bulky volumes on Social Evolution are the most comprehensive survey of the historical development of mankind yet made by any one writer; in Austria by Gumplowicz, whose *Der Rassenkampf* and *Grundriss der Sociologie* are works of keen insight and great suggestiveness; in Germany by Bachofen, Lilienfeld, Poste, Dargun, Bastian, Ratzell,

and Waitz; in England by the two McLennans, Tylor, Frazer, and Karl Pearson; in the United States by Lewis H. Morgan, Franz Boas, and the Bureau of Ethnology; [in Italy, by de Bella, de Marinis, and Mazzarella—E.M.]. All of these have made important contributions to our knowledge of the structure of primitive and of tribal society, including the evolution of the family, clan, and tribe.

While ethnological methods have given us our only exact knowledge of the origin and historical development of society, statistical methods give us our only accurate knowledge of the social phenomena of modern populations: the facts of the distribution of races and nationalities, of emigration and immigration, of birth-rates and death-rates, of marriage and divorce, of partnerships, corporations, and other forms of co-operation, of travel and communication, of pauperism, crime, philanthropy, and religion. Statistical methods have been refined and extended since Quetelet's day, and in every country men of great ability have devoted their best energies to statistical investigation—men like Engel and Meitzen in Germany, Bodio and Morselli in Italy, Levasseur in France, Longstaff, Galton, and Pearson in England, Walker, Wright, Adams, and Mayo-Smith in the United States.

It is, however, only through psychological analysis that the real nature of society and of social processes can be understood, and recent work in sociology has more and more strongly emphasized the psychological factors and conceptions. The psychologists themselves, notably Baldwin and Royce in the United States, have made most important contributions to social psychology in their investigations of the part played by social relations in the evolution of the individual mind. Imitation, invention, and the social judgment have been subjected to thorough examination in their works. Among strictly sociological writings, Bagehot's illuminating book on *Physics and Politics* (1872) broke ground in many new directions, and especially by the importance it attached to imitation and to natural selection as processes of the first importance in social evolution. It was, however, the epoch-marking work of Tarde, *Les Lois de l'Imitation*, which elaborated and firmly established the psychological sociology. Other works by the same author (especially *La Logique sociale*); by Sighele and Le Bon (who have paid especial attention to the psychology of crowds); by Durkheim and Novicow, have traversed large

SOCIONOMIC FORCES

portions of this field. As psychological sociology must also be classed the work of de Greef in Belgium, who has elaborated the idea of the SOCIAL CONTRACT (q. v.), and of Giddings in the United States.

Whatever method or combination of methods shall ultimately be found most satisfactory, a complete scheme of sociological investigation must include a study of (a) the elements or factors that combine in social phenomena; (b) the mental activity of masses or communities of men, as distinguished from that of individuals, as such; (c) the various forms of social organization; (d) the material and moral results of social organization; and (e) the historical evolution of society and of social groups and types. The problems of sociology (F.H.G.) or of the SOCIAL SCIENCES (q. v., 2 above, J.M.B.), thus fall naturally into the two groups—problems of historical development (comparative and genetic) and problems of contemporaneous phenomena (analytic and quantitative): Those of the second group (put first by F.H.G.) are naturally subdivided into (a) problems of the social population, (b) of the social mind, (c) of the social organization, (d) of the social welfare. The problems of (1) sociology proper (J.M.B.) or the historical development of social association (F.H.G.) or AGGREGATION (q. v., J.M.B.), in like manner fall naturally into the subgroups (i) genetic and (ii) comparative. Under (i) we have (1) zoogenic association (those social habits of animals which were antecedent to human society); (2) anthropogenic association (the beginnings of human society); (3) ethnogenic association (the development of tribal society); and (4) demogenic association (the evolution of civil society); and under (ii), the relations of these forms to one another, with the laws of the evolution of the higher from the lower forms. Cf. the table given under SOCIAL SCIENCES. (F.H.G., J.M.B.)

Socionomic Forces. Forces, themselves not social, which condition or direct the operation of SOCIAL FORCES (q. v.) and so enter into the determination of social organization and progress. Cf. SOCIONOMICS (also for derivation and equivalents), and FORCE AND CONDITION.

The relation of these to the social forces properly so called is similar to that which the psychologists recognize between the strictly psychological and the physiological. The various states of the body, such as intoxication, fatigue, starvation, and over-nourishment, affect the mind, and so influence the individual's mental development; but we do not call these psychological forces. They are of psychological value only because, through the sorts of stimulation and limitation which they afford, they condition certain uniform results in the psychological organization itself. The analogy thus cited—between the extra-social influences with the effects they bring about in the social whole, and the extra-mental or physiological influences with their influence upon the individual's mental life—is indeed more than an analogy. When we reflect, we find that it is through the connection of mind and body—one term of the analogy—that the extra-social forces—the

other term of the analogy—get their value. It becomes, therefore, still more apparent that we cannot call the influences enumerated below social forces; for so far are they from showing direct value in the organization of society, that they become factors in that organization only by the indirect road of stimulation to the nervous system of individuals. It would be just as appropriate to call blood-changes psychological facts, as to call physical changes, such as the cutting of the Suez Canal, social facts; yet both undoubtedly deserve recognition in a philosophical statement of all the determining conditions in these two branches of knowledge.

Cf. the present writer, *Soc. and Eth. Interp.* (3rd ed.), sect. 313 a—a passage of which this article is in part a reproduction. It seems that Comte made essentially the same point in distinguishing between what he called 'secondary conditions'—in which he included not only the physical (4, below), but also competition (1 and 2, below)—on the one hand and true 'causes'—the mental factors—on the other hand (see Barth, *Philos. der Geschichte als Soziol.*, i. 33 ff.).

The most important of these conditions are the following:—

(1) GROUP-SELECTION (q. v.). In group-selection we have a condition of enormous importance in the development of social aggregations, especially in the instinctive and spontaneous periods; that is, so-called 'companies.' It holds, however, for all societies when the conditions are such that groups as groups come into competition. Not only real war, but commercial and social wars of all kinds, illustrate group-selection. Cf. RIVALRY (3).

The working of the principle is analogous, indeed identical, with that of natural selection in biology—a point excellently worked out by Bagehot in his remarkable work *Physics and Politics*. It is one of the foundation stones also of S. Alexander's work *Moral Order and Progress*. Bagehot acutely recognizes the distinction, without explicitly drawing it, between group-selection as a condition of evolution in the earliest stages of human aggregation, and the operation of the real social force of 'discussion' ('social generalization') in the higher. It is, moreover, an additional proof that group-selection is a condition, and not a social force, that there is such a difference between the lower and the higher; for the lower are determined, as is said above, very largely by biological principles, such as instinct and

physical heredity, and do not involve the social progress which later on the operation of the psychological forces brings in. Yet it is in the lower that group-selection is all-important.

(2) INDIVIDUAL SELECTION (q. v.), which is natural selection working upon individuals who are brought into competition for life and death with one another. For instance, let us suppose that a man of genius who has not yet given to the world his invention—the machine which, if produced by him, would have great influence upon the condition of the working classes—that this man meets a burglar in his library and is shot dead. Here is a case of natural selection which determines the course of social evolution in a nation or in the world by the elimination of an individual. Such a case shows that the natural selection of individuals is a condition of importance—when the individuals are important—in social development. But it is not a force even in biology. It is a negative condition; a statement—in sociology as in biology—of evolution as it is, the conditions being what they were. This again is of especial importance in those stages of sociality in which the direct competition of individuals by physical strength or mental acuteness is in full operation.

(3) *The intrusion of the 'physiological cycle.'* The 'cycle of causation' which psychological and sociological facts, such as beliefs, desires, &c., represent, often intrudes upon the operation of the 'physiological cycle' by the personal selection of individuals in marriage. The physical heredity of the individuals is due to the mixed strains of the parents, and hence is in part determined by their mutual choice of each other. The converse is also true: the physiological intrudes upon the sociological, and thus becomes an 'extra-social condition' in its determination. This is seen in all cases in which physical heredity works results in individuals or groups which incapacitate them, especially endow them, or modify in any way their social fitness. A tall manly race of men would have social advantages in winning wives from a higher group, and such marriages would tell at once inside their own group. Where social preferment depended upon physical prowess, the inherited club-foot would be an element of social unfitness. In the fact of what is called physical 'presence,' probably largely a matter of posture and vitality, we all recognize an easy substitute in many social positions for brains, culture, or oratorical gifts.

Yet these things are not in themselves social; nor can they by any manipulation become social. The influence they have is entirely through the psychological states of which they are the conditions. A man with the illusion of a club-foot would be as helpless as if it were real. And where is the hero so commonplace that his 'presence' is not lordly to some love-sick maid?

(4) *Physical conditions*: 'the broken earth and the vaulted sky,' the canal and the river-course, the mountain and the meadow. These, we are told, determine social development. They do; but by conditioning it, by intrusion upon it, by limiting it, not by being themselves social. That they are never. Let a race of animals that cannot think, nor recognize a social situation, nor know one another as reciprocating and fulfilling social give-and-take, run over the meadows and swim in the rivers, under a sky never so blue—and what effect of a social kind would these physical things have upon them? But given the psychological traits, make them men—and then what would not the human race do even on the levellest plain? Here again we have extra-social conditions. The land and water condition separation and segregation, competition and mutual defence, toleration and alliance, commerce and confederation; but the essentials of social matter and process must be there, and it is they that work under these conditions or those. Again an illustration from recent biological theory—a case which often turns upon the effects of such physical differences: the facts of ISOLATION (q.v.) have been said to represent a biological force, since, when animals are isolated from each other, the race is prevented from having the in-mixture of their hereditary strains, and so the heredity of the race is prelimited. True, as a fact; but why make an abstraction do duty for a force? Isolation is always accomplished by some real force—say a whirlwind which blows away the isolated individuals; but the biological forces are the life processes in those which are left. The whirlwind is the condition by which the result has been in a measure negatively determined; but who would say that the whirlwind is a biological force? At the most it is an intrusion of physics into the biological cycle. Just so with all the physical changes considered as influencing social life and development: they are conditions, intrusions from physics; not social forces.

(J.M.B.)

Socionomics [Lat. *socius*, companion, + Gr.

vómos, law]: Ger. *Sozionomik*; Fr. *socionomique*; Ital. *socionomia* (E.M.). A term suggested to designate the science of the relation of social groups to their environment, including other social groups; analogous to BIONOMICS, and PSYCHONOMICS (see those terms). It is the theory of SOCIONOMIC FORCES (q.v.). (J.M.B., F.H.G.)

Socius [Lat. term for companion]: Ger. *Socius*, *Genoss*, *Gesell*; Fr. *socius*, *compagnon*; Ital. *individuo sociale*. The self of the individual's consciousness in so far as it implicates another self or ALTER (q.v.) in a social situation; called also 'social self.'

The conception of the social self is sometimes made to mean a collective self-consciousness common to a group (Espinass, *Les Sociétés animales*); this is argued against by many (see Fouillée, *La science sociale contemporaine*; and Barth, *Philos. der Geschichte als Sociol.*, i. 150 ff.; cf. also Barth's own view, 153 ff.).

That the socius is, in fact, the normal self, and that the self apart from recognition of social relationships (see INDIVIDUALISM) is an abstraction, was held by Comte (see also Barth, loc. cit., 55, and his preface to Baldwin's *Social and Eth. Interpret.*, Ger. trans.).

Suggested by the present writer (*Social and Eth. Interpret.*) in this general sense, the determination of the content of the socius and its social meaning being different at different stages of growth. See also Ormond, *Psychol. Rev.*, Jan., 1901. (J.M.B.—G.F.S.)

Socrates. (469–399 B.C.) Born and educated at Athens. Took part in three military campaigns, in 432, 434, and 422 B.C. He spent his life teaching the people of Athens, by a dialectic, conversational method peculiar to himself, ideas which he believed necessary to the salvation of the national life of Greece. Condemned to drink the cup of hemlock, technically for 'corrupting the youth and introducing strange deities,' but really because his teachings and method had placed him out of harmony with his judges. He was the teacher of Plato. See SOCRATIC PHILOSOPHY, and SOCRATIC METHOD.

Socratic Method: Ger. *Sokratische Methode*; Fr. *méthode socratique*; Ital. *metodo socratico*. The procedure of inductive approach to generalizations by question and answer; called also the 'dialogic method.'

The Dialogues of Plato represent the Socratic method as having two distinct parts; first the Socratic irony, and second the inductive approach to generalizations by means of question and answer. Many of his hearers were

Sophists, who made great pretensions to wisdom. It was often necessary to refute them by showing the absurdity of the positions they attempted to maintain. For this purpose the Socratic irony was employed. When a teachable frame of mind was secured, a serious attempt was made to discover fundamental definitions, especially of ethical notions, by means of inductive questioning. The Socratic method is rightly honoured to this day, and must indeed be reckoned as an important element in any perfected procedure in instruction. See METHOD (in education).

Literature: XENOPHON, *Memorabilia*, Bk. IV. chap. ii; much of the literature of PEDAGOGICS (q. v.). (C. DE G.)

Socratic Philosophy: Ger. *Sokratische Philosophie*; Fr. *philosophie socratique*; Ital. *filosofia Socratica*. The philosophy which was determined as to its method, and in part as to its aims, by Socrates. In the broadest sense this would include the so-called 'Socratic Schools' (see SCHOOLS OF GREECE) and their successors. The Stoic Epictetus, for example, constantly appeals to Socrates. In this article the term will be restricted to the philosophy of Socrates and his two most distinguished and all-sided followers, Plato and Aristotle.

In these three we may distinguish (1) a thorough appreciation of the social, political, and moral life of the Greek city, and an increasingly successful effort to analyse this and give its theoretical statement. (2) Springing out of this and developing in connection with it, a growing consciousness of the necessary *method* to be pursued—at first in the discovery of ethical principles, then, more generally, in any scientific investigation. The way here lies from the discussions of Socrates with his teachers and the man on the street, through the more comprehensive and subtle divisions and dialectic of Plato, to the clear consciousness of method formulated in the systematic logic of Aristotle. (3) In Plato and Aristotle the construction of a theory of reality, based, in Plato's case, jointly upon his ethical and methodological views, and, in the thought of Aristotle, upon methodological and physical considerations. (4) An analysis of the aesthetic life in its appreciations and creations. (For this see ART THEORIES, and BEAUTY.)

The thought of Socrates has been preserved mainly in the writings of his two disciples, Xenophon and Plato. In the latter's

Dialogues it is sometimes difficult to say what is purely Socratic and what is Plato's own, but in general it is considered that the more distinctly metaphysical discussions, the more elaborate dialectical investigations, and the doctrines connected with the belief in the pre-existence and immortality of the soul (see PSYCHE) fall under the latter class. The problem of Socrates was set by his conviction, on the one hand, that a merely habitual and conventional morality no longer sufficed—'an unexamined life is not worthy of man'—and, on the other, that underneath moral codes and political laws lay a basis for a theory which could justify itself fully to the reason. In the first of these convictions he shared the free thought of the Sophists (see PRE-SOCRATIC PHILOSOPHY), and was accordingly classed with them by the popular mind and by the conservative Aristophanes, who represented Socrates as the arch-Sophist, teaching irreverence, substituting natural agencies for the ancient gods, and training his disciples 'to make the worse appear the better reason.' But whereas the Sophists either did not seek or did not find a new authority to replace the old, an inner law to replace the external code, Socrates both sought and found such a new standard. The Sophists were mainly wandering teachers, with the freedom of life and thought frequently found in the man who has no civic or family responsibilities. For such a life individualism is a natural position. Socrates was above all the citizen of Athens, whose conception of life meant life as a member of a city-state. In seeking to discover what is 'good,' the younger Sophists particularly meant 'good for the individual,' and found as their answer 'the full, uncramped development of the impulses and desires.' Socrates sought 'the good,' which must commend itself as such to the public-spirited citizen, and which had found expression in laws and institutions. True to the genius of Greek life, he found it in knowledge, in insight. Excellence (*ἀρετή*), which in Homer's day had been manly valour, is now declared to be knowledge; and since it is not to be supposed that a man will intentionally injure himself, as he must do if he misses the good, no one can be regarded as doing wrong (i.e. as pursuing evil) voluntarily. All wrong-doing is due to ignorance. Many, if not most, are ignorant of the true good, and need to be stung into a consciousness of their ignorance. Socrates conceived it to be his duty to enlighten his fellow citizens, to

SOCRATIC PHILOSOPHY

convince them of their ignorance, and in the fulfilment of this task he incurred that personal resentment which combined with the more general grounds noted above in causing his trial and conviction on the charge of 'corrupting the youth and introducing strange deities.'

It was in the effort to discover the good which is not determined by individual desire, but is universally valid, that Socrates developed his *method*. Assuming that there is such a general good, it ought to be discovered as the common element in all particular instances, and in the ideas of different men. Socrates therefore endeavoured to elicit the opinions of all whom he met, to criticize and compare the views presented, and finally to gain a definition, a general concept. The method of delivering others of their opinions Socrates called his art of 'maieutic' or mental midwifery, and the accompanying profession of his own ignorance was made with a sometimes playful, sometimes satirical 'irony' (see Plato's *Theaetetus* and *Gorgias*). This confidence in the objectivity of the general conception is an illustration of the general Greek position that the mind can apprehend only what already exists objectively—a position which found further illustrations in Plato's doctrine of ideas (below). The method, however, contained the fundamental principle of all scientific inquiry in so far as this analyses facts to find laws or general concepts.

In the Dialogues of Plato we have religious, ethical, theoretical, and artistic interests combining to give a view of the world and of life which has exercised permanent mastery in the world of thought, and furnished apparently inexhaustible suggestion, largely because of this comprehensive inclusion and interpretation of human experience. The ethical, logical, and aesthetic problems develop side by side. The religious conception of immortality and the 'other world' comes in to give definite imagery to the demand for a distinction between the relative and the absolute, between the changing and the permanent, and a metaphysics frames a theory of reality embodying all these elements.

Plato's early ethical inquiries raise the question whether there can be a science of conduct. If all the various virtues may be reduced to one, and this one wisdom, it is apparent that some single principle underlies all the recognized 'goods.' The next question

is, What content is to be assigned to the good thus analysed? The Cyrenaics (see SCHOOLS OF GREECE) had suggested 'pleasure.' If this be accepted (cf. the *Protagoras*), wisdom will find its part simply in measuring the more and the less. But there are several reasons why this identification of the good with pleasure cannot be admitted. (a) Pleasures cannot be weighed objectively. Their respective values will depend upon who is judge. It is therefore the character or wisdom of the man which determines the value of the pleasure, and not the quantity of pleasure which determines the good. Education aims to teach the young to find pleasure in the right objects—not to find the greatest quantity of pleasure, no matter how or where. (b) Knowledge is not merely an agency for measuring values; it is itself a value, an element in the perfect life. (c) The aesthetic demand for a complete, harmonious life requires a normal fulfilment of functions, not an intemperate intensification of desires and their gratifications. (d) 'The good' is a social category. If it is absurd to call a man good because he is experiencing pleasure, it is because the true good for man is discovered to lie only in the fulfilment of his function in the state. (e) Finally—and here the religious conception of the PSYCHE (q. v.) enters to give a new turn—the immortal life of the soul introduces quite another set of values, which are not relative, like the exchange of one pleasure for another, but absolute. Union with God, assimilation in character to God—this is the absolute good.

Plato's logical discussions led to the same culmination. The RELATIVISM (q. v.) of Protagoras (see PRE-SOCRATIC PHILOSOPHY) was admitted to apply to perception by the senses, but declared suicidal if applied to reflective thought (cf. the *Theaetetus*). Knowledge is impossible without the use of such conceptions as those of likeness, difference, and equality. These cannot be discovered by perception. 'The soul discovers the universals of things by herself.' But the soul cannot discover these universals in the particulars of experience. It cannot find a 'one' in the 'many.' There is no absolute equality or absolute goodness in this world. Whence then does the soul obtain such universals? The Greeks did not recognize a creative activity of thought, but the religious dualism already noted afforded an answer. The psyche has seen these universals in its previous existence,

where it has beheld truth, beauty, and goodness absolute—separate from any particulars. The experiences of this world suggest, but do not contain universals. They remind the soul of its former vision (cf. the *Meno*, *Phaedrus*, *Phaedo*). Some of the difficulties implied in this theory, according to which particulars which contain no true universal are yet to be known by an external universal, were recognized by Plato (in the *Parmenides*, if this is Plato's) and further developed by Aristotle. The doctrine of 'recollection' or 'reminiscence' is not always emphasized or even mentioned, and may not have been regarded by Plato at all periods of his thought as a necessary element in the system. But the distinction between two kinds of knowledge was fundamental. Perception can give only opinion; reason or reflective thought may give scientific knowledge.

To these two kinds of knowledge correspond two spheres or worlds of reality. The object apprehended through perception is a world of change, of generation and corruption. The reality apprehended through rational thought is the world of true being (*οὐσία*). This world of true being has its characteristics determined by all the *motifs* stated above. As the true home of the soul it has the qualities which Orphic and Pythagorean had embodied in their ideal of the 'other world.' As the world of absolute knowledge it must be the world of universals, separate from particulars of sense, of the changeless 'IDEAS' (q. v.). As the world which is of supreme value, it must be a world in which that intelligence and measure are expressed which belong above all to the good. The 'Idea of the Good' is of controlling significance (*Republic*, *Philebus*), and even in the world of change it finds some manifestation (*Timaeus*). For the maker or Demiurge (*δημιουργός*) of this world looked to the eternal pattern and made the world good and fair. The good, through this mediating conception of a Demiurge or Deity, becomes not merely a static universal, but a dynamic agent, i. e. a causal as well as a conceptual relation is sought. Cf. also WORLD-SOUL, which is another mediating conception. The things of this world are also sometimes regarded as 'participating' in the Ideas, or as copying them as ectypes copy archetypes.

It follows therefore that he who would know the true good, even for human life, must lift his consideration beyond the particulars of sense and study the ultimate good. The ideal

state will be governed by the 'philosophers' who seek the absolute good, and their education will be directed to this end (*Republic*).

What Plato had thus sharply contrasted in the two worlds of 'becoming' and 'being' Aristotle attempted to bring together. But he aimed to preserve the values of the universal, and of that other world which Plato had separated from the particulars of experience in his effort to bring out its values. That knowledge involves the reference of every particular to some universal, a deduction from some general, Aristotle asserts in his LOGIC (q. v.). His doctrine of the SYLLOGISM (q. v.) exhibits one form of such a use of the universal to explain a particular brought under it by some middle term. But he insists that the general which is to explain the particular cannot be a separate, abstract universal. For in that case the particulars would still remain particulars, unrelated to it or to each other. And so in conceiving reality, instead of the two unrelated or scarcely related worlds—the one of particulars, the other of universals, the one of changing process, the other of changeless substances—Aristotle substitutes one world of individuals, each of which is neither mere particular nor yet abstract Idea,—neither wholly unrelated to its preceding state, nor yet a static, changeless entity. Reality is conceived as DYNAMIC (q. v.). Aristotle's terminology for this conception (see GREEK TERMINOLOGY) is that everything in nature is both FORM (q. v.) and MATTER (q. v.), both ACTUALITY (q. v.) and POTENTIALITY (q. v.). Motion is the transition from the potential to the actual. The true substance is the individual as thus constituted, and is at once a realization of one form and a potentiality of another. The seed is an actual organization of its material up to a certain stage; at the same time it is potentially a plant. Another analysis or explanation of the individual is that by the four causes (see CAUSE): material, formal, final, and efficient. These four may be distinguished in the case of a work of art. In an organic product of nature the last three are not distinct. One qualification must be added to the above statements. While there can be no matter without form—nothing merely potential with no actuality—there may be Pure Form, complete actuality or energizing. This Pure Form corresponds to Plato's 'Idea of the Good.' Its activity is to be conceived as νόησις νοήσεως, self-conscious

reflection. This corresponds to the religious ideal, the deity. This Pure Form is the prime mover, the first cause of all motion, but it operates as a final cause, through the intrinsic longing of matter to take on form. In other words, while the transcendence of the Pure Form is asserted, Aristotle seeks also to avoid reducing the world to the abstract matter of the materialists. It should further be noted that in addition to the conception of matter (*hyle*, ὕλη) as the potential and as the correlate of 'form,' Aristotle employs the term with a more positive connotation. It is the substratum, the subject of growth and decay, the source of inherent qualities. It is an accessory cause (see IDEALISM).

Aristotle's conception of reality as organized or formed matter found illustration in his view of the soul as the entelechy of the body (see PSYCHE). His aim to unite the elements which Plato separated is well shown in his *Ethics*. The good of man cannot be determined by any 'absolute' idea of good; it must be sought rather in human well-being (*eudaimonia*). But on the other hand this well-being is to be sought in the complete development or realization of the part of man which is most peculiarly human, to wit, the rational nature. The 'practical' virtues involve a rational control of habit or impulse—the fundamental Greek principle of 'measure' or 'limit' here finds its place—and may be regarded as each a 'mean' between extremes; but still higher than the practical virtues stand the intellectual. The highest ideal is found in contemplation of the truth.

The general change in emphasis towards a more completely intellectual conception of the meaning of wisdom, which is disclosed in the development from Socrates to Aristotle, finds expression not only in this ethical ideal, but in the whole scope of Aristotle's investigations. The whole field of existing knowledge was surveyed; new investigations were undertaken in such widely diverse provinces as those of comparative politics, literary criticism, psychology, and comparative anatomy; many sciences were practically organized *de novo*. Finally, the increasingly theoretical trend from Socrates is illustrated in the respective attitudes towards the state. Socrates was eminently a citizen of Athens, caring not to live unless he could live in Athens and influence its life by his teaching. Plato, in disgust with the actual city which could put to death its teacher, constructed in the

Republic an ideal state whose pattern was 'laid up in heaven.' The philosopher's citizenship is in this better city. Aristotle is at one with Socrates and Plato in recognizing the social and political nature of man, but the changed political situation which had one type of expression in the individualism of the Stoics, Epicureans, and Sceptics, favoured in Aristotle a scientific and theoretical rather than a reforming or idealizing temper. His work on *Politics* is largely an historical and comparative study of the various forms of polity. Plato's *Republic* has been the inspiration of religious and social ideals. Aristotle's *Politics* furnished conceptions for secular theories of the basis of institutions.

Solger, Carl Wilhelm Ferdinand. (1780-1819.) Born at Schwedt in Uckermark, he was educated at Berlin, Halle, and

Jena Universities in philology, jurisprudence, and philosophy. In Jena he heard Schelling, and later, in Berlin, Fichte. Owing chiefly to the influence of the latter he gave up the practical pursuits which had before occupied his attention, and in 1804 devoted himself to learning. He became Privatdocent in Berlin, and studied Spinoza as well as Fichte and Schelling; habilitated (1809) in Frankfurt a. d. Oder, and lectured in philology and philosophy. In 1811 he moved to Berlin as professor of philosophy. There he died.

Solidarity (social) [Lat. *solidus*, firm]: Ger. *Solidarität* (cf. SENTIMENT, social); Fr. *solidarité*; Ital. *solidarietà*. The union of individuals in a social whole, together with the social sentiment which characterizes each of the individuals (see Barth, *Philos. der Geschichte als Sociol.*, i. 27, with exposition of Comte's view). Cf. SOCIAL ORGANIZATION, SOCIAL TISSUE, and SOCIUS. (J.M.B., F.H.G.)

Solidity: see IMPENETRABILITY, and MATTER.

Solipsism [Lat. *solus*, alone, + *ipse*, self]: Ger. *Solipsismus*; Fr. *solipsisme*; Ital. *solipsismo*. Subjective IDEALISM (q. v.) as follows in (1) to (3):

(1) As theory of knowledge: the doctrine that since knowing is a subjective process in the mind of an individual, what is known must always be either the self or some modification of the self. Or, stated negatively, the doctrine that nothing can be known except the self and its modifications or states.

(2) As metaphysics or theory of reality: the doctrine that nothing but the self exists.

(3) Subjective idealism as metaphysics is often used to cover theories, like that of Berkeley, which deny the independent existence of an external material world, although such theories do not usually deny that some reality in addition to the individual subject exists, and hence cannot be properly called solipsism.

(4) Kant uses the word as an ethical term (*Werke*, ed. Hartenstein, v. 77) in the sense of self-seeking, practical egoism, but this has not been followed by English writers. Cf. SELF-LOVE, ad fin.

The argument for solipsism is thus stated by Bradley: 'I cannot transcend experience, and experience must be *my* experience. From this it follows that nothing beyond my self exists, for what is experience is its (the self's) states' (*Appearance and Reality*, 248).

If the attitude of solipsism is defined rigorously, it would be difficult to name

historic representatives of the theory. It may, however, be taken as the limit towards which certain theories logically tend, if consistently pursued, and hence in the following, the tendencies coming under (3) above will be noted as well as the more rigorously defined solipsism.

Speaking generally, modern philosophy from the time of Descartes, as contrasted with ancient philosophy, has found its starting-point in self-consciousness, and has viewed the existence of other reality than itself as a matter of inference rather than of immediate certainty. Ambiguities in the conception of the 'self' have led to a confusion of the position that all experience and all objects of experience must be within consciousness, and the metaphysical position, on the other hand, that the consciousness, or the 'self' just referred to, must be regarded as an exclusive subjective process. The subjective direction was given to modern philosophy by the position of Descartes, that knowledge of the self is the primary certainty, whereas the existence of God and of an external world may be doubted, until these are seen to be necessary grounds of certain ideas found within the self. This view, that the existence of all except the self and its ideas is a matter of doubt or inference rather than of immediate knowledge, is called by Kant 'problematic idealism.' Locke takes a similar attitude, maintaining that 'since the mind hath no other immediate object but its own ideas, which it alone does or can contemplate, it is evident that our knowledge is only conversant about them' (*Essay*, IV. i. 1). He, however, holds that we have an 'intuitive knowledge of our own existence, a demonstrative knowledge of the existence of a God, a sensitive knowledge of some few other things.' Metaphysically, Locke has no doubt of the existence of a world of things corresponding to our ideas—except as regards the secondary qualities of colour, sound, &c.—but he admits that its existence cannot be demonstrated. Berkeley, agreeing with Locke that immediate knowledge is only of the self and its ideas, and that the existence of God is demonstrable, denies the existence of an independent material world, on the ground that to suppose such an existence would commit the absurdity either of supposing that conscious sensations or ideas could exist apart from consciousness, or of supposing that some entity, which is not itself an idea, could be like an idea. A similar position as

regards the existence of a material world was reached by Arthur Collier (*Clavis Universalis*), but, like Berkeley, he did not question the independent existence of God and other spirits.

Descartes, Locke, and Berkeley had all assumed the self to be an independent substance, or self-existing entity, and had relied upon the principle of causality to demonstrate the existence of God as a distinct entity. Hume assailed both these positions. He accepts unreservedly the doctrine that all the contents of experience must be some aspect or mode of 'consciousness.' Our world is the 'world of the imagination,' and we can never transcend this. But the concept of cause cannot be relied upon to carry us beyond our own perceptions. The existence of any external cause for our impressions is a matter concerning which we can make absolutely no affirmations. The impressions may be produced by God, by external objects, or by the mind. Belief in the existence of an external world is due to a propensity to feign a separate and continued existence for our perceptions. While, therefore, Hume did not dogmatically assert the sole existence of the self, he had reached the position which Kant characterized as 'a scandal to philosophy and to human reason in general,' that we should have to accept the existence of things without us (from which we derive the whole material of knowledge for our own internal sense) on faith only, unable to meet with any satisfactory proof an opponent who is pleased to doubt it.

Kant sought to meet this position of solipsism by better analysis of the meaning of self-consciousness. He maintains that while all objects of knowledge are necessarily objects of consciousness, the distinction between subject and object, or between the empirical 'self' and the outer world, is a distinction within consciousness, and not a distinction between consciousness and something outside of consciousness. In fact, the external is logically prior to the internal, since it is only as contrasted with the external that the internal self, as existing in time, is definitely conscious of itself as such. Kant, however, was not entirely consistent in his expressions upon this point, and as certain of his later fragments show, he connected the proof for the existence of objects within consciousness with the proof of the existence of things by themselves, since an appearance without something that appears would be a logical absurdity.

Fichte, though making the 'I' the central principle of his system, was not a solipsist, for the 'I' of his science of knowledge was not the individual. His problem was rather the analysis of the general conditions of consciousness. Mill, in his definition of the external world as permanent possibilities of sensation, repeated the Berkeleyian analysis. Recent discussions between Neo-Kantians and Realists (see REALISM) have turned very largely upon ambiguities above referred to.

Solon. (cir. 638-cir. 558 B.C.) A native of Salamis, and a merchant by education and profession, he travelled much in Greece, Western Asia, and Egypt, acquiring the knowledge which made him the statesman and lawgiver of his native city. He was the first archon of Athens, and gave to the city the democratic organization which led to its greatness. He died during the war against Pisistratus. He was one of the greatest of 'law-givers' and was one of the 'seven wise men' of ancient Greece. See CODE (in law).

Solutio [Lat. *solutio*, from *solvere*, to melt]: Ger. *Lösung*; Fr. *solution*; Ital. *soluzione*. (1) The solution of a geometrical problem consists in: (a) describing a construction; (b) proving that that construction would satisfy the requisita of the problem; (c) proving that the construction is possible when the problem has any solution.

(2) The solution of an equation or system of equations has various meanings in different branches of analysis. Only in elementary algebra does it mean giving an algebraical equation of which the unknown forms one member while no unknown enters upon the other side.

(3) The answer to a general speculative problem of pure deductive logic: how can a given form of relationship hold good? (C.S.P.)

Soma [Gr. *σῶμα*, body]: same in other

languages. The mortal portion of the body in opposition to the sexual elements, which continue the life in the next generation. Cf. GERM-CELLS.

In this sense the term has been used only since the publication of Weismann's theories (see his *Germ-Plasm*). (C.S.M.)

Following Weismann, somaplasm is used for the substance and tissues of the body constituting the soma in contrast with the germplasm of the germ-cells. Only the latter, on Weismann's view, are the bearers of heredity, modifications of the somaplasm having no effect on the next generation. Cf. WEISMANNISM. (J.M.B.)

Somaplasm : see SOMA.

Somatology [Gr. *σῶμα*, body, + *λόγος*, discourse]: Ger. *Somatologie*; Fr. *somatologie*; Ital. *somatologia*. (1) A synonym for physical anthropology, or the study of the physical part of man.

The use of this term would avoid the confusion between the several meanings attached to anthropology, as well as meeting the need for descriptive adjectives in connection with it. Somatology as a division of anthropology includes an account of the structure of the human body, the skeleton, and internal organs; the proportions of the parts of the body (ANTHROPOMETRY, q. v.) and the special study of the brain; the developmental and comparative facts in regard to the body and body-growth; and throughout, the utilization of all these facts for the differentiation of man from his nearest animal kin, as well as the differentiation of human races, tribes, peoples, nations, or special classes (men of genius, criminals, &c.). It would thus constitute, in the most comprehensive sense, the description and systematic exposition of our entire knowledge regarding the body, with special reference to the application of such knowledge to the problems of anthropology. See for further details and for literature ANTHROPOLOGY, and ANTHROPOMETRY.

(2) In theology: see PSYCHOLOGY (empirical and rational). (J.J.)

Somatopleure (in embryology) [Gr. *σῶμα*, body, + *πλευρά*, wall]: Ger. *Somatopleura*; Fr. *somatopleure*; Ital. *somatopleura*. The primitive wall of the body formed by the union of the ectoderm and outer or somatic leaf of the mesoderm.

The term was introduced by Michael Foster in 1875. It is often used incorrectly in Germany to designate the somatic mesoderm.

Literature: FOSTER and BALFOUR, *Embryology*; F. M. BALFOUR, *Compar. Embryol.* (1881); MINOT, *Human Embryol.* (C.S.M.)

Some (in logic): Ger. *einige*; Fr. *des, quelques*; Ital. *alcuno, qualche*. (1) The mark of a 'particular' proposition, i.e. of that modification of the subject of a proposition which limits the predication to an indefinite part of the subject class. See PROPOSITION, IV.

It is thus equivalent to 'at least some' and does not assert or deny concerning all; i.e. it is not equivalent to 'only some' (see definition 2). (J.M.B.)

(2) A mark which fits a proposition to be the precise denial of a universal proposition. Cf. ALL (2). (C.S.P., C.L.F.)

The latter definition is held by those who hold that the particular asserts the existence of the subject while the universal does not. This is, however, a matter for difference of opinion. Definition (1) is the commonly accepted one. (J.M.B.)

No practical difficulty need arise from this difference of opinion: it is only necessary to add statements of such existences as the parties to the discussion believe to be involved. (C.L.F.)

Somnambulism [Lat. *somnus*, sleep, + *ambulare*, walk]: Ger. *Schlafwandeln*, *Somnambulismus*; Fr. *somnambulisme*; Ital. *sonnambulismo*. Literally, walking in one's sleep; more generally, a mental condition of partial sleep, or intermediate between sleep and waking, in which purposive acts are performed.

Talking, singing, writing, answering questions in sleep without awaking, may thus properly be regarded as instances of somnambulism. The presence of a sleep condition is shown by the limitation of sensibility, frequently by the closure of the eyes, by the unimpressiveness to ordinary stimuli, and by the complete forgetfulness of what was done during the somnambulatory state. Some of the senses are automatically alert, particularly the muscle sense: thus somnambulists rise from their beds, properly direct their steps, avoid obstacles, and walk along dangerous places, such as the parapet of a roof, with safety and freedom from fear. In other cases hearing is responsive to suggestions made by bystanders. In many cases the train of thought carried out is a continuation of that with which the mind was occupied during the day. The oft-quoted instance of the mathematician who was surprised to find written out at his

bedside the solution of a problem which he had vainly attempted during the day, illustrates the automatic continuation of mental activity and the presence of a delicate muscle sense in the guidance of the hand in writing (provided it happened!).

The case of a girl who found in a later somnambulistic condition the locket which she had hidden in a former (but the whereabouts of which she could not recollect in her waking state) illustrates the connection of one somnambulistic state with the others. For these and other reasons the state is allied to HYPNOSIS (q. v.) and other forms of automatism, which by reason of this analogy first received the name of artificial somnambulism. In a few cases (mostly hysterical women) the somnambulism occurs spontaneously, apart from the nocturnal sleep, and corresponds most closely to the hypnotic condition. States of religious ecstasy are often of this nature, and were termed by the older writers 'ecstatic somnambulism.' When the plastic rigidity of the limbs was present (see CATALEPSY) the condition was termed 'cataleptic somnambulism.'

The tendency to somnambulism, i. e. simple nocturnal walking, talking, &c., is an index of nervousness, and is a symptom often met with in the life-history of nervous disorders. It is often, also, merely an incident of rapid growth, or of temporary conditions such as indigestion. The more developed forms of somnambulism are almost invariably associated with abnormal functional conditions of the nervous system. Cf. HYSTERIA.

Literature: CARPENTER, Ment. Physiol.; TUKE, Sleep-walking and Hypnot. (1884). (J.J.)

Son of God: Ger. *Gottessohn*; Fr. *Fils de Dieu*; Ital. *Figlio di Dio*. The name of Jesus Christ which indicates his divine as distinguished from his human nature and origin, and also his relation to the Father in the Trinitarian conception of the Godhead. See CHRIST.

Literature: see CHRIST, and CHRISTOLOGY. (A.T.O.)

Sonant: see PHONETICS.

Sonometer: see LABORATORY AND APPARATUS, III, B, (b), (3).

Sopater: see ALEXANDRIAN SCHOOL.

Sophism [Gr. *σοφός*, wise]: Ger. *Sophisma*, *Trugschluss*; Fr. *sophisme*; Ital. *sofisma*. (1) The best authorities, as Trendelenburg (*Elementa Logices Aristotelis*, 5th ed., § 33), define a sophism as an intentionally deceptive syllogism.

It is evident that, so defined, the science of logic cannot concern itself with them; and accordingly some logicians have maintained that this was not the proper definition, a contention in which they were aided by the circumstance that Aristotle in his book of *Sophistici Elenchi* omits entirely the class of fallacies which a writer upon the subject would naturally think of first.

(2) A false argument which, without deceiving, is difficult to refute logically.

Although logic cannot concern itself with reasonings intended to *deceive*, as such, yet it has the nearest interests with pretended arguments intended to 'wind up' an antagonist, so that he does not know how to reply to them, and in the early days of the science they, no doubt, contributed much to the development of it. They are occasionally useful still. To be so, the less they deceive, while the more unanswerable they seem, the better. (C.S.P.)

Celebrated sophisms or paradoxes (for which the logics—Prantl, *Gesch. d. Logik*, Eisler, *Wörterb. d. philos. Begriffe*, &c.—should be consulted) are the 'Achilles,' the 'arrow,' the 'heap,' the 'ignava ratio' arguments, and in connection with the theory of PROBABILITY (q. v.), the 'Petersburg problem.' (J.M.B.)

Sophistry (1) and (2) **Sophists** [Gr. *σοφιστής*, a Sophist, in general a clever or wise man, from *σοφός*, wise; more specifically, a teacher or philosopher]: Ger. (1) *Sophistik*, (2) *Sophisten*; Fr. (1) *sophistique*, (2) *Sophistes*; Ital. (1) *sofistica*, (2) *Sofisti*. (1) Fallacious reasoning intentionally employed, from the alleged practice of the Sophists, who were charged by their critics, Plato, Aristophanes, and others, with an unscrupulous use of quibbles, ambiguities in terms, and other fallacies, by which they made the worse appear the better reason.

(2) Teachers of various subjects, especially rhetoric and oratory, who came into prominence in the second half of the 5th century B.C. Socrates was popularly identified with them (see SOCRATIC PHILOSOPHY). The more important Sophists were Protagoras of Abdera (about 480-410 B.C.), Gorgias of Leontini (483-375 B.C.), Hippias of Elis, Prodicus of Ceos. The chief sources are from their opponents, e. g. Aristophanes in the *Clouds*, Plato in the Dialogues, *Protagoras*, *Gorgias*, *Theætetus*, *Cratylus*, *Euthydemus*, and *Sophist*. Cf. also Xenophon's *Memorabilia*, II. i. 21, for Hippias. For their position and teaching see PRE-SOCRATIC PHILOSOPHY.

Literature: M. SCHANZ, *Die Sophisten*

(1867), and the literature under PRE-SOCRATIC PHILOSOPHY. (J.H.T.)

Sophists: see SOPHISTRY AND SOPHISTS, and PRE-SOCRATIC PHILOSOPHY.

Sorcery and Soothsaying: Ger. *Magie*; Fr. *sortellerie, magie*; Ital. *magia, stregoneria*. An art founded on the belief or pretence that the powers supposed to preside over nature can by the performance of certain spells or incantations be controlled for the production of phenomena beyond the ordinary powers of man or nature. See MAGIC.

Sorcery and soothsaying have been associated mainly with the spirits of evil. But their secret, so far as they have any, seems to be identical with that of magic in general. The rôle played by magic in ancient and mediaeval life constitutes an important chapter in human history. The mediaeval art of which Paracelsus was one of the most famous practitioners, but which numbered among its adherents some of the most distinguished names in science and philosophy, rested on a theosophic basis, and grew out of the sciences, if such they may be called, of alchemy and astrology. As a matter of fact the art, in so far as it had any real basis, rested on a knowledge of nature which was as yet a mystery to the public.

Literature: HOWITT, Hist. of the Supernatural (1863); FABART, Hist. philos. de l'Occulte, Magie, &c. (1885); FROST, The Magicians. See MAGIC. (A.T.O.)

Sorites [Gr. *σωπείρης*, a heap]: Ger. *Kettenschluss*; Fr. *sortite*; Ital. *sortite*. (1) A name (Valla) for a chain of syllogisms, the conclusion of each forming a premise of the next.

Only one kind of sorites is commonly recognized in logic, but according to the way of arranging the premises it is called Goclenian or (without reason) Aristotelian. The latter brings into juxtaposition the two occurrences of each middle term. (C.S.P.)

(2) Applied to a Megarian sophism of the 'heap.' Cf. SOPHISM. (J.M.B.)

Sorrow [A.S. *sorg*]: Ger. *Trauer*; Fr. *tristesse*; Ital. *tristezza*. Synonymous with (1) GRIEF (q. v.) and (2) REGRET (q. v.).

Soteriology [Gr. *σωτήρ*, deliverer]: Ger. *Erlösungslehre*; Fr. *sotériologie*; Ital. *soteriologia*. That branch of Christian theology which treats of the salvation of man through the atoning and redemptive work of Jesus Christ.

The current statement that the early Christian thinkers developed the theological and anthropological departments of general

theology, while its soteriology was left largely to post-Reformation thinkers, contains a measure of truth. A more accurate conception, however, will be obtained by distinguishing between the theological and anthropological aspects of Christology, and bearing in mind that while the early thinkers were chiefly interested in determining the doctrine of Christ's nature and relation to the Godhead, later thought has been chiefly concerned with the human side of Christ's work and the scheme of salvation growing out of it.

Literature: BAUER, Die christl. Lehre v. d. Versöhnung (1838); RITSCHL, Die christl. Lehre, &c. (1870); EDWARDS, Justification and Wisdom in Regeneration; A. A. HODGE, Theology, ii; SHEDD, Hist. of Doctrine, i. 201-386. (A.T.O.)

Soul (1) and (2) **Soul Theory:** Ger. (1) *Seele*, (2) *Theorie der Seelensubstanz* (see TERMINOLOGY, German, 'Seele'); Fr. (1) *âme*, (2) *théorie spiritualiste*; Ital. (1) *anima*, (2) *teoria dello spiritualismo*. (1) The mental principle considered as a substance separate from the body, having personal individuality and identity, of which the individual mental life and development are manifestations. Cf. MIND, SPIRIT, NOUS, PSYCHE, and PNEUMA.

On the historical development of the concepts soul and mind, see the extensive citations given under the topics 'Seele' and 'Geist' in Eisler, *Wörterb. d. philos. Begriffe*. The Greek usage divided the meaning between *voûs* and *ψυχή*, seeing that the conception had a later development in the scholastic and patristic literature, in which the Latin term is *anima*. See the lexicons of Biblical Greek (especially Hastings and Cheyne, *Dicts. of the Bible*), and Hebrew (especially *New Heb. Lexicon*, B. D. B.). (J.M.B.)

(2) The theory that there is a substantial human soul, independent of the body, of which the individual mental life and development are manifestations.

The soul theory is part of the substance theory, which recognized a dualism between mind and body. Its more recent rivals are phenomenalism, actuality theory, and the various forms of quasi-materialism and automatism, to which the phrase 'psychology without a soul' has been applied.

Literature: recent discussions are LOTZE, *Microcosmus*; JAMES, *Princ. of Psychol.*, i. 180ff., 343 ff., and index, 'Soul Theory'; S. HODGSON, *Met. of Reflection*; LADD, *Theory of Reality*, chap. xv; ROYCE, *The World and the Indi-*

vidual, sect. ii; MONTAGUE, *A Plea for Soul Substance*, 2 arts., *Psychol. Rev.* (1899); DE SARLO, *Il concetto dell' anima nella psicologia contemp.* (1900). See also the literature of SPIRITUALISM, and of IMMORTALITY. (J.M.B.)

Soul (in theology). The non-corporeal and spiritual individuality of man. That which thinks, wills, and feels, conceived as a perdurable entity and a subject of conscious spiritual experience; the spiritual principle in man. Cf. SOUL AND SOUL THEORY.

Theologically, the soul must be distinguished from the body, inasmuch as immortality is predicated of the soul. A threefold distinction (called TRICHOTOMY, q.v.) is sometimes made between body, soul, and spirit, in which case soul is conceived as a middle term between the bodily organism and the spirit. In general, when soul and spirit are not used synonymously, soul represents spirit in potentia, while spirit is the developed energy of the soul in the sphere of moral and religious experience.

Literature: see THEOLOGY, and IMMORTALITY. (A.T.O.)

Sound: see HEARING, II, and TONE.

Sounds (vocal): see PHONETICS, and cf. SPEECH.

Sovereignty [L. Lat. *superanus*, supreme, through Fr.]; Ger. *Souveränität*; Fr. *souveraineté*; Ital. *sovranità*. Sovereign power; the power of the person or persons supreme in a political community and not subject to any other person or persons. Cf. STATE (philosophy of).

The term sovereign is correlative to the term subjection, and both are implied in the term 'political community' (see STATE OR COMMUNITY). According to Austin, where the bulk of the members of a society are habitually obedient to a given person or body of persons, and that person or body of persons is not habitually obedient to any other person or body of persons, that society is an independent political community, and that person or body of persons is sovereign, the other members of the community being in a state of subjection. Austin speaks of obedience on the part of the bulk of the society in question, because in every society there is a criminal class which is not in habitual obedience; and of habitual obedience, because a great many persons occasionally disobey the sovereign. Again, he speaks of the political superior as not being in habitual obedience to any other person or body of persons, because almost all political

superiors have occasionally been obliged to obey the orders of other potentates. According to Austin's description of sovereignty, sovereignty is a matter of fact, not of law or courtesy, and the sovereign, in his sense of the term, is often quite distinct from the person or persons so entitled. According to Austin, sovereignty is incapable of legal limitation, since the political superior who could be bound by law would be the subject of a higher authority. He would of course admit the reality of moral and physical limitation. Further, according to Austin, all law is the command of the sovereign, for unless he enforces obedience, a rule is destitute of that sanction which distinguishes legal from moral rules.

This description of sovereignty is very useful as giving us an abstract conception which may help us in classifying and describing actual sovereigns. But there are few cases in which it tallies with all the facts of political association. Austin was unduly influenced by consideration of the most civilized societies; especially of the Roman empire and the United Kingdom. The historical development of sovereignty, like the historical development of the political community, has been slow. The ruling authorities of the family, the village, and the city have merged only by degrees in the ruling authority of the state. Ecclesiastical authorities have divided sovereignty with political authorities. In modern times the desire to divide powers and balance authorities so as to hinder oppression has produced constitutions (notably that of the United States) in which it is hard to discover any sovereign such as Austin describes. Austin considers legislative power the distinguishing attribute of sovereignty, but except in the most civilized communities direct legislation is rare, and the ruling authority is chiefly concerned with the interpretation and enforcement of law. The only authority whose power is always free from legal restraint is the public opinion, not necessarily of the whole community, but at all events of the effective portion of it, whether priests or warriors or nobles or rich or educated, or however else determined.

Literature: HOBBS, *Leviathan*; LOCKE, *Civil Government*; ROUSSEAU, *Contrat Social*; BENTHAM, *Fragment on Government*; AUSTIN, *Jurisprudence*; MAINE, *Early Hist. of Instit.*; HOLLAND, *Jurisprudence*. (F.C.M.)

Sovereignty (of God): Ger. *Unumschränktheit* (*Gottes*); Fr. *souveraineté* (*de*

Dieu); Ital. *sovranità* (*di Dio*). That unconditional control which God by inherent right of his nature is supposed to exercise over the world, and especially over man and his spiritual destiny.

The great issue which arises in this connection is that between God's sovereignty and man's free and responsible agency. This issue constitutes the great watershed of theology, and Christian thinkers have been Augustinians or Pelagians according as the supreme emphasis was placed on one side or the other. The ancient issue has been fought out in modern times between Calvinism and Arminianism. The classical utterance in behalf of the divine sovereignty in modern thought is that of Jonathan Edwards, who asserts God's inherent right to the absolute disposal of his creatures.

Theol.*, Loc. iv; EDWARDS, *The Will, and The Divine Decrees*; CUNNINGHAM, *Hist. Theol.*, chap. xxv; KUYPER, *Calvinism*. A very full bibliography is given by COPINGER, *A Treatise on Predestination*. The relevant sections in the best Biblical theologies should be consulted, especially DILLMANN on O. T. and HOLTZMANN on N. T. (A.T.O.)

Space [Lat. *spatium*]: Ger. *Raum*; Fr. *espace*; Ital. *spazio*. The abstraction of the mutual externality of objects actually perceived or thought as coexisting in possible experience, and represented as a continuous homogeneous magnitude of three dimensions, infinitely divisible and limitless in extent. The philosophy of space treats of the logical and real nature of that which is so represented.

The first Greek thinker to attempt a definition of the nature of space was, as Aristotle tells us (*Phys.*, iv. 2, 209 b 17), Plato; Aristotle himself was the first to elaborate the problems and investigate them systematically. The way for these inquiries, however, had been prepared. Anaximander's qualitatively 'unlimited' substance was also boundless in extent; it gives birth to innumerable worlds, and still, as Hippolytus reports (*Ref. Haer.*, i. 6), encompasses them all. Similarly of Anaximenes' 'air.' Among the Pythagoreans 'the unlimited' appears to be identified with

pure space. All things are 'number' which, in reference to physical things at least, is conceived geometrically. The ultimate units are points. Bodies are geometrical solids (*Plut., Plac.*, ii. 6, 5). The world is formed from a fixed centre by successive determinations of adjacent portions of 'the unlimited' (*Arist., Met.*, xiv. 3, 1091 a 17), the cohering portions being separated from one another by intervals of 'the void.' Outside the boundary of the world is an infinite, also conceived, apparently, as empty space (*Arist., Phys.*, iii. 4, 203 a 1). Yet it would be a mistake to suppose that the Pythagoreans thought of 'the unlimited,' 'the void,' and solid bodies as pure abstract space or determinations of pure space, for of the infinite beyond the stars they thought, as Aristotle tells us (*ibid.* iv. 6, 213 b 22), as 'infinite breath' which the world inhaled. Space is conceived realistically and with only partial abstraction from its content. 'The unlimited' is at once infinite space and infinite stuff, and in general it seems truer to say that space is thought of as a material substance than to say that matter is thought of as pure space.

Till the time of Plato the question with regard to space which then interested philosophers was primarily the question as to the existence or the non-existence of empty space. The Eleatics, Empedocles, and Anaxagoras denied its existence. Zeno, indeed, is generally thought to have gone still further and to have denied the existence of any space whatever; but this is probably a mistake. His argument, as reported by Simplicius (*Phys.*, iv. 562, 3-6), runs thus: 'If space (or place, *ὁ τόπος*) is, it must be in something; for everything that is is in something, and so in space. Space then will be in space, and so *ad infinitum*. Therefore space is not.' But the major premise, 'everything that is is in something,' cannot possibly have been held true by Zeno, for it is completely at variance with the Eleatic conception of Being. But it may very well have been urged against the Parmenidean doctrine of the One Being, considered as a physical plenum 'equal in all directions' and 'equally contained within limits,' that such a being must exist somewhere, and that therefore there must also 'be' empty space surrounding it. It is altogether probable that it is this objection which Zeno here meets, exposing, on the objector's own assumptions, the inconveniences for thought which arise when space is thus abstracted from body and regarded as a thing apart. If this interpreta-

tion is correct, the argument is directed not against the existence of space absolutely, but against the existence of empty space¹. The Atomists, on the other hand, believed that empty space was necessary to explain motion.

It is the metaphysically more fundamental idea implicit in the Pythagorean theory, the idea of the identity of space with matter, which Plato takes up and which he first explicitly formulates, setting it forth from the point of view of his own more developed philosophy in a new light. He distinguishes space (*Tim.*, 49 ff.) both from ideas and from sensible things which are their copies. It is a third class of being, resembling ideas in that it is eternal, indestructible, and ever the same, but differing from them in that it is, in itself considered, utterly formless and void. It differs, moreover, from both ideas and things in being apprehended neither by reason nor by sense, but by a sort of 'bastard reasoning' (*λογισμῶ τινὶ νόθῳ*), a phrase indicating perhaps that, while abstract space can be thought 'pure,' it is not, like the proper objects of intelligence, metaphysically real. It is, however, the substrate (*ὑποδοχή*) which 'receives' all things and so takes on different appearances according to the character of that by which it is informed. Plato likens it to the mother, the father being the idea, the child the sensible thing, its image. How space becomes impregnated by the idea, and how sensible things are generated in it, he does not explain; on the contrary, he fully recognizes the mysteriousness of the relations thus metaphorically referred to. He speaks of space as a thing fairly incredible, difficult of explanation, most difficult to comprehend. The more precise interpretation of his thought will depend on the view taken of his philosophy as a whole. Viewed as a consistent system of absolute idealism, in which is merged a subjective idealism as regards the relation of the material world to finite percipients, space, one aspect of the 'other' present along with true 'substance' in the world-soul, will appear perhaps as the immutable and eternal law of finite perception, the form in which finite intelligence apprehends the ideas existing in infinite intelligence. And this will then be

Plato's meaning: space is just a form of sense-perception. But though there is much, especially in the *Timaeus*, to suggest this interpretation, most commentators think that Plato is less explicit than this, and the subject is too complicated to be discussed here¹.

In striking contrast with Plato's speculative treatment of the subject is the abstractly logical discussion of Aristotle in the fourth book of the *Physics*. The discussion here takes the definite form of an inquiry concerning the space (*ὁ τόπος*) in which any object is situate. That such space exists distinct from body is proved by the fact that different bodies successively occupy the same space. Moreover, it has its own positive character, for the relations in it of up and down, &c., are fixed in nature and are not relative to us or like mathematical magnitudes, whose positions are determined by thought. But what is it? What is its 'genus'? It cannot be a body, for then two bodies would be in the same place. But neither can it be a pure object of thought, for such objects have no magnitude. Nor is it, again, any of the four 'causes': it is neither the matter of which anything is composed, nor its determining form, nor its efficient cause, nor its end. Again, if it exists, where is it? as Zeno so effectively asked. And if it coincides in size with the body it holds, when the latter grows, must not it grow with it? These perplexities, which Aristotle presents in his usual 'aporetic' fashion, show clearly enough the difficulty of regarding space as a really existent 'thing.' Proceeding to the development of his own views, Aristotle examines at some length Plato's identification of space and matter. His main argument equally applies against its identification with form; it is that matter and form are inseparable from things, whereas space is separable and contains things². His

¹ The view referred to is ably maintained by R. Archer-Hind in his edition of Plato's *Timaeus* (London, 1888).

² Aristotle's criticism of Plato is unsympathetic as usual. He sees no difference between their respective problems. He misrepresents Plato in making him say only that space is matter, his real doctrine being rather that matter is space. This he conceives as wholly homogeneous and immovable. Sensible things are modes of its manifestation. Change of place would be, therefore, metaphysically speaking, not at all a translation of matter, but a readjustment in the relations of the sensible appearances, generated by ideas, in the one unchangeable space. Of course there is the difficulty, which Aristotle does not fail to notice, as to the participation in space of unspatial ideas; but the objection tells equally against Aristotle's own doctrine of 'form.'

¹ See Bäumker, *Problem d. Materie in d. griech. Philos.*, 61. Cf. Burnet, *Early Greek Philos.*, 330. Zeno's arguments against multiplicity and motion, framed, apparently, with reference to the Pythagorean doctrine of the composition of space-things out of separate space-units, do indeed prove indirectly, by reference to the infinite divisibility of space, the absurdity of regarding space as independently real.

reply to Zeno is, that there are other ways in which a thing may be 'in something' than by being in it as a place; it may be in it, e. g., as a *ἕξις* or a *πάθος*; we are not, therefore, necessarily involved in the infinite regress. But if the space is neither matter nor form of the body, it is either the interval between its boundaries (*διάστημα τι τὸ μεταξὺ τῶν ἐσχάτων*) or the boundaries themselves. Aristotle rejects the former of these hypotheses on the ground, apparently, that it implies the separability in nature of the interval or body's extent, with the consequence that every space must both contain an infinite number of spaces and must itself be in a space. He adopts, therefore, the remaining hypothesis and defines the space of a body as the limit, more particularly as 'the first unmoved limit of the containing body' (*τὸ τοῦ περιέχοντος πέραν ἀκίνητον πρῶτον*, loc. cit., 212 a 20).

With this definition Aristotle believes that he meets all the difficulties, for it explains space not as a thing in space, but as a stable relation between bodies. And it has this as a consequence, that it gets rid at a stroke of empty space as an entity existing either within the world or without it. 'Heaven,' the world's outermost boundary, and accordingly the world itself taken as a whole, is for Aristotle not in any place, for no body exists beyond it to limit it. But the definition, valuable as it is as the first suggestion of the relational idea of space, is manifestly faulty. Granting that space is but the abstraction of corporeal relations, and that, apart from such relations, it has neither existence nor significance; granting even the finiteness of the material world, despite the representation which necessarily makes every boundary related to space beyond as well as to space within, still it cannot properly be said that either space in general or the space occupied by a body capable of moving out of it is merely a boundary or limit. A spatial limit is itself a determination of space which serves to determine a space, but is not a part of the space included within it. And the attempt to determine that in turn by limits would seem to be frustrated by the infinite divisibility of space. Aristotle's definition is, in fact, not a definition of space, as such, at all; it is merely a statement of the way in which the place of a physical body in space is to be determined. And even so it shows little appreciation of the subtleties connected with the idea of spatial limit or boundary. What, for example, becomes of the unmoved limit

when the enclosing body moves? In view of these difficulties, and in view of the ambiguities in the statement itself, it is not surprising to find that the definition was rejected not only by the Platonizing Simplicius, who criticizes it severely in a lengthy excursus in his commentary on the *Physics*, but also by Aristotle's own disciple and successor, Theophrastus. Theophrastus inclined to the view that a space consisted in the arrangement and position of bodies¹.

After Aristotle the discussion was again taken up concerning the existence of the void, the Epicureans maintaining its existence both within the world and outside it, the Stoics denying its existence within, but holding that it extended infinitely beyond², while Strato conversely denied it for the outside, but, to account for the interpenetration of bodies by light and warmth, assumed it for within³. With the Stoics, again, matter, and hence space, is infinitely divisible; with the atomistic Epicureans not even space is infinitely divisible⁴. In these discussions the realism in the conception of space is full-blown. Nothing of any value is contributed to the elucidation of the conception, unless we except the purely formal distinction of the Stoics between the space filled by a body (*τόπος*), the void (*κενόν*), and space (*χώρα*) which includes both (Stob., *Ecl.*, i. 382). With the Neo-Platonists, on the other hand, space must be an expression of, or an element in, the world-soul, and, in a sense, ideal; but a modern reader can find little that is clear in their confused and contradictory accounts of it. Plotinus says, in apparent disagreement with Plato, that the space a body fills is not matter, since bodies must first have matter before they can be in space (*Ennead.*, ii. 4, 12). Iamblichus, who makes space a genus including both the corporeal and the incorporeal, and the deity the ultimate place of all things, says that perhaps bodies occupy space only *κατὰ συμβεβηκός*, and that a space, a surface, and 'the substrate' are the same thing; he defines their place physically now as the surface of the surrounding, now as that of the surrounded body, and again as the force which holds them together

¹ Fr. 21, 22, Zeller, *Philos. d. Griechen*, II. ii³. 831 f. For Simplicius see Zahlfleisch, 'Die Polemik des Simplicios (Corollarium, 601-45, des Commentars ed. Diels) gegen Aristoteles' Physik, 1-5, über den Raum,' *Arch. f. Gesch. d. Philos.*, 85-109.

² This was the common view; Posidonius, however, considered it finite.

³ Zeller, op. cit., II. ii³. 909.

⁴ See Bäumker, op. cit., 309.

and makes their extension¹. Proclus regarded space as the purest light, corporeal but immaterial (Simpl., *Coroll. de loco*, ed. Diels, 612).

From the foregoing brief survey of opinion among the Greeks it appears that there was a general agreement among all schools that space was something objectively real and not merely relative to us. The opposite view was implied perhaps in the empiricism of Protagoras and other forms of Greek scepticism, but it does not seem to have been developed to a positive doctrine. Even the Eleatics probably formed no exception, in spite of the logic which, strictly taken, would make not only space but everything thinkable an illusion². And although the idealistic systems did not regard it as absolutely real, as did the materialistic systems with their doctrine of the void, but rather as an element in a world constituted of mind, yet they too would seem not to have considered it as a mere mode of representation in finite souls apart from their participation in the universal world-soul. But there was the greatest diversity of opinion with regard to the nature of its reality. With some (materialists) it is a sort of second entity along with body; with others (Pythagoreans, Plato) it is the matter which is determined to body by the action of some higher principle; then, again, it is an internal energy which gives extension to bodies (Iamblichus) or a quasi-immaterial body (Proclus). With Aristotle, on the other hand, taking it in its determinate character as the place of body, it is regarded attributively as a relation. Then, again, there was a difference of opinion as to its extent. Aristotle, believing the world to be finite, was bound to assert the finiteness of space, thus introducing a contradiction between real and mathematical space. Parmenides held a similar opinion. The general opinion was that it was infinite. This involved the contradiction of the completed infinite. The same contradiction was involved, relatively to the infinite divisibility of space, in the Pythagorean doctrine of the unit. The dialectic of Zeno developed these contradictions. Thus already in Greek philosophy are represented all, or nearly all, of the fundamental differences of view possible regarding the nature of space: space is either objective or subjective, either real or ideal, either a thing or an attribute

or a relation, either finite or infinite, either composed of ultimate units or infinitely divisible. Many of the difficulties connected with these various views are also more or less clearly indicated.

The great schoolmen—Albertus Magnus, Thomas Aquinas, and Duns Scotus—commented subtly on the fourth book of Aristotle's *Physics*, but the characteristic mediaeval interest in the question of space is theological. Space is a creation. Intelligible space, therefore, precedes real space. Beyond the confines of the material universe, 'imaginary' space stretches in *infinitum*. The question then was, how can God, a pure spirit, be omnipresent in the immensity of real space without being extended or localized? Aquinas answered, by his power, essence, and omniscience (*Sentent.*, I, 37, 1, 2; *S. T.*, I, 8, 3). But even so the contradiction remains of a real infinite and infinitely divisible whole summed up in a single act, or else the idea of real space as such a created whole, and consequently the idea of intelligible space also, would seem to be an illusion. Later, when Copernican astronomy suggested the illimitableness of the material universe, men like Nicholas of Cues and Giordano Bruno expressed the logic of the contradictions involved in real infinity in the doctrines of the *coincidentia oppositorum* and the identity of maxima and minima¹. On the formal side, the statements in the old philosophical lexicon of Goclenius may fairly be taken as representing the prevailing opinions: 'Spatium est aliis intervallum finitum, in quo aliquid est vel esse potest. . . Aliis spatium est capedo, seu intervallum vel finitum vel infinitum' (*Lex. philos.*, 1067).

The characteristic advance made by modern philosophy lies in the development of the subjectivistic view of space. The opposite doctrine, however, was long the prevailing one. Descartes made extension the essence of corporeal substance (*Med.*, vi; *Pr. Philos.*, ii. 10-8), believing not only in its reality, but in the infinite divisibility of its parts (*Letters to Mersenne*, 115, 119). Spinoza made it one of the attributes of God (*Eth.* i, Prop. xv, Sch.). Locke, while rejecting the Cartesian identification of space with body, held no less strongly to its objective reality, though, professing to have no clear idea of substance, he refused to express any opinion

¹ Zeller, op. cit., III. ii³. 706.

² See in proof the *Parmenides* of Plato.

¹ Cf. Renouvier, *La Critique philosophique*, Suppl. 5 (1882), 281 f.

as to whether it was a substance or an accident (*Essay*, ii. 13). Newton taught the reality of absolute space (*Princ.*, 6, ed. 1726), regarding it as the sensorium, as it were, in which God had immediate perception of the material universe (*Optics*, App.). The Newtonian doctrine was upheld by Samuel Clarke in his famous controversy with Leibnitz¹, in which he declared space to be an immediate and necessary consequence of the existence of God, the property of an incorporeal substance, and the place not only of bodies, but also of ideas (Fourth and Fifth Replies). Leibnitz, on the other hand, contended that space was nothing but an order of coexistences, as which it continued to be defined in the Leibnitzian school. Strictly interpreted, the Leibnitzian doctrine makes space a subjective phenomenon, bodily extension being but the representation in unspatial monads of their mutual exclusiveness, their 'passive force'; but the laxer interpretation, according to which space, as such, and not merely its analogon, is objectively and metaphysically real, was the commoner². The subjectivistic trend is characteristic of British philosophy. After Hobbes, contradicting other parts of his system, had defined space as 'phantasma rei existentis, quatenus existentis,' and had declared it to be 'imaginarium quidem, quia merum phantasma' (*De Corp.*, vii. 2), and after Locke had opened up that pathway of ideas from which no pathway of philosophy appeared to lead back to the common-sense assumptions of existence he had started from, the decisive step was taken by Berkeley of asserting absolute space to be a phantom (*Sir.*, 271), pure space the mere possibility of bodily motion (*Pr.*, 116), and extension in general, along with the other sensible attributes of matter, merely ideas in us. The most effective of his arguments is derived from the perception of magnitude: as every assignable magnitude of a body depends on subjective conditions, it is vain to suppose the existence of an absolute magnitude (*First Dialogue between Hylas and Philonous*). Hume's scepticism will not allow him to say anything regarding existence absolutely, but his analysis of the space element in our experience is similar. Attacking the assump-

tions of the infinite divisibility of space and the exactitude of mathematics, he affirms that 'the idea of space or extension is nothing but the idea of visible or tangible points distributed in a certain order' (*Treatise*, Pt. II. § 5).

But the doctrine of the subjectivity of space which stands prominent above all the doctrines of space in modern philosophy is the Kantian. It is the modern doctrine *par excellence*, representative in the same sense in which Aristotle's doctrine was representative of Greek philosophy. Kant's views, as set forth in the *Critique of Pure Reason*, are in substance as follows: (1) the idea of space is not empirical in its origin, since in referring a sensation to a place in space, it is already presupposed; (2) it is *a priori* necessary, since we cannot think it non-existent, though we can well think everything contained in it non-existent; (3) it is not a general conception under which species or individuals are subsumed, but an intuition in which all particular spaces are contained; (4) it is represented as an infinite given magnitude; (5) the apodictic certainty of geometry, an *a priori* science of space determinations, can be explained only on the theory that space is merely the form of external perception. He concludes that space is nothing inhering in the nature of things *per se*, but is merely the subjective condition of sensibility, under which alone external perception is possible to us. In the antinomies which result from taking the extended sensible world as independently real, he found a striking confirmation of this theory. The uniqueness of the theory becomes evident when we compare it with the views of previous thinkers. The leading opinions in modern times have been: (1) that space was something real, independent of the human subject, either the essence of corporeal substance (Descartes) or the property of a substance (Spinoza), containing all bodies or even all things (Newton, Clarke); (2) that it was purely subjective, being given in and with particular impressions of sight and touch (Berkeley); (3) that it was subjective as representation, but also objective, so far as the perceptions of sense represented an analogous order of relations in things themselves (Leibnitz). Kant's doctrine is opposed to, and at the same time mediates between, all three. It holds with the first that space is an all-embracing something, so far as concerns the things in space, but this something is our form of intuition; it holds

¹ The writer calls attention to the note in Kuno Fischer's *Gesch. d. n. Phil.* ii, 2. Aufl., 42: 'Wir schreiben den Namen "Leibniz," nachdem festgestellt worden, dass der Philosoph selbst sich nie anders geschrieben.' [Both spellings are allowed to stand in this work—J.M.B.]

² See Vaihinger, *Commentar zu Kant's Krit. d. reinen Vernunft*, ii. 147, 416 ff.

with the second that space is subjective, but distinguishing between the general form and the particular content of experience, denies that it is empirically given; and it holds with the third in opposing a world of things *per se* to the world of our sense-perceptions, but making the opposition still sharper, finds no ground for applying the conception of space as extensive magnitude to anything but the latter.

A full account of the discussions growing out of Kant's doctrine would fill volumes: every point has been attacked and defended over and over again. The more important criticisms relate to (1) the alleged subjective source of the idea; (2) the doctrine that space is *merely* subjective; (3) the proof of this from geometry; (4) the proof from the antinomies. The doctrine in (1) is rejected, of course, by all empiricists. Others find the argument vitiated by psychological assumptions concerning the origin of ideas; they deny that the elements in experience can be separated, in the way Kant tries to separate them, into those which have their source in the subject and into those which do not; they hold that experience is both subjective and objective throughout, and see in Kant's formulation of his doctrine a faulty expression of the truth that, reflecting on the constitution of its experience, the mind discovers that space is logically presupposed as a condition of its possibility, and is in this sense *a priori*, but only in this sense. As regards (2), it was early contended, and later notably by Trendelenburg in his controversy with Kuno Fischer¹, that Kant's arguments, even granting that they suffice to prove the subjectivity of space, fail to prove that it is not also objective, and that Kant, in drawing his conclusions (1st ed., 26), overlooked the possibility that it might be both. The objections rest, partly at least, on confusion. For if 'objective' means valid of objects, this is precisely what Kant asserted was true of space relative to the objects of possible experience. If, on the other hand, 'objective' means having an existence *per se* apart from relation to possible experience, Kant cannot be said to have overlooked this possibility, since his argument was expressly designed to refute it. If space were a property of things-in-themselves, he says, we could not determine its nature *a priori*, 'for no determination of

objects . . . can enter into our intuition before the actual existence of the objects themselves.' Such knowledge, he says elsewhere (*Proleg.*, § 9), would be unintelligible—it could only rest on inspiration; the doctrine in this reference of pre-established harmony seemed to him fantastic. Nevertheless, there is force in the contention that Kant's argument does not disprove the possibility of a natural conformity of the constitution of our minds to the constitution of things, and it is plausible to assume this conformity, assuming that our knowledge is real. This assumption again may be carried out in many ways, leading to many different theories of space. (3) Kant assumes as the foundation of his theory the apodictic certainty of Euclidean geometry. This assumption eminent mathematicians have since contested, chiefly on the ground that Euclidean geometry rests on an indemonstrable hypothesis concerning parallel lines. Other hypotheses are therefore equally possible; and on them accordingly other systems of geometry, containing notions of the constitution of space widely divergent from the Euclidean, may be, and indeed have been, constructed. The necessity, therefore, which Kant's theory was intended to explain does not exist. It is admitted that non-Euclidean space cannot be separately intuited, and this agrees with the Kantian doctrine of the relative subjectivity of space as we actually intuit it: other forms of space are possible; but, on the other hand, this very possibility shows the merely factual or empirical character of at least all that in our intuition in which Euclidean differs from non-Euclidean space. At best, therefore, it is not our form, but only some form, of space which can be regarded as *a priori*, i. e. as the indispensable prerequisite of a possible experience¹. Finally, as regards (4) Kant's proof from the antinomies, its value is denied by all who, like Wundt (*Syst. d. Philos.*, 352 ff.), resolve the apparent conflict into a mere 'Scheingefecht,' or who, like Lotze (*Met.*, §§ 106 ff.), find the same or similar contradictions in Kant's own theory. Others, without following Kant closely, admit the general principle involved; Renouvier, for example, concluding from the contradiction in the conception of the actual infinite that space is a pure intuition and its infinity merely potential (*Traité de logique gén.*, i. 50),

¹ For a full account of this dispute see Vaihinger, *op. cit.*, ii. 290-326.

¹ So e.g. B. A. W. Russell, *The Foundations of Geometry* (Cambridge, 1897); F. Medicus, 'Kant's tr. Aesth. u. d. nicht-eukl. Geometrie,' *Kanistudien*, iii. 261.

while Bradley makes space 'mere appearance' on the ground that it is dialectical and contradictory through and through (*Appearance and Reality*, Bk. I. chap. iv).

The general result of the discussion of Kant's doctrine has been to produce a widespread conviction that space is nothing absolutely real, either as a thing or as a determination of things; but also, on the other hand, that it either is or represents more than a mere form with which we invest the objects of our perception, but which, apart from our perception, has no sort of reality in the nature of things. For even if the general representation of objects as external in space be regarded as due to the subjective conditions of our sensibility, the compulsion we are under to represent their space relations in a definite order affords the strongest motive for regarding those relations at least as objectively determined. Accordingly, in the great systems of idealistic philosophy which succeeded the Kantian criticism, we find, even with Fichte in his later period, that the externality of phenomena in space is represented as due not specially to the subject as opposed to the object, but to the activity of a principle identical in the subject and the object (Fichte, *Werke*, i. 190; cf. 343, viii. 415; Schelling, *Werke*, i. 3, 22 ff.; Hegel, *Werke*, vii. 44 ff.; *Logik*, i. 279, iii. 353; *Encyc.*, § 244). The realistic Herbart, with the principle, 'wie viel Schein, so viel Hindeutung auf Sein,' opposes to phenomenal an 'intelligible' space (*Met.*, ii. 200 ff.), as denoting the fact of a real order of coexistence in the multiplicity of elements posited as absolutely real, although, as Trendelenburg justly observes (*Log. Untersuch.*, i. 190), the latter is modelled entirely on the former. Trendelenburg himself holds that space is not the presupposition, but the product, of motion (*ibid.*, 215 ff.). Other systems tend to a revival of the view of space implied in the Leibnitzian spiritualism (Lotze: 'every particular feature of our spatial intuition corresponds to a ground in the world of things,' *Met.*, § 113. Wundt: objective space, after elimination of subjective elements, is 'the regular order of a manifold consisting of particular independently given real objects,' *Logik*, i. 463). Among original thinkers of the first rank, Schopenhauer alone accepts the Kantian doctrine without reserve. Amid this conflict of opinion, the Kantian criticism and the whole subjective trend of modern philosophy seems to have made one thing clear, and that is that space is a category which has neither meaning nor validity beyond the

bounds of possible experience. If, therefore, we refuse to accept the naive conception that the object is one thing and its idea in the mind a mere counterpart and copy, we must admit that there are not two spaces, one real for things and one ideal for minds, but that ideal space is only the abstraction of real space, and real space only the realization of the ideal. Whatever reality, therefore, and whatever ideality belong to objects in space belong to space also. Hence everything depends on the interpretation of experience. Cf. SPACE-PERCEPTION, and EXTENSION. (H.N.G.)

Literature: besides the citations made above, see BIBLOG. B, 2, *j*, and G, 2, *v*; see also EXTENSION, and the numerous quotations in EISLER, *Wörterb. d. philos. Begriffe*, 'Raum.' (J.M.B.)

Space (in mathematics). The totality of all the positions into which a body could possibly be moved, were no impediment to motion in existence.

This totality forms a continuum (see CONTINUITY, in mathematics), the conception of which is so elementary and fundamental that no definition can materially aid in its formation. For us the parts of space are all those places, infinite in number, to which or in which a body can be conceived to move or exist, and, vice versa, we can conceive any body to move into a part of the infinite continuum which is formed by the totality of those places. Space is continuous not only in the sense that every part joins to the parts around it, but that every part is susceptible of indefinite subdivision.

Our fundamental conception of space assigns to it these properties:—

(1) It is the same for all bodies. Wherever one body could move, thither could any other body move.

(2) It is triply infinite. A point may move independently in three independent directions, all perpendicular to one another, called dimensions, to an infinite distance.

(3) It has no qualities or *differentia* dependent either on position or direction. Wherever a body may be situated, its capacity of movement is the same for all positions and for all directions.

(4) It is homoloidal. Two parallel straight lines may be produced indefinitely without either converging towards or diverging from each other.

On these properties is based the science of geometry. Mathematicians have, however,

posited spaces in which the second and fourth properties are modified in various ways. Such hypothetical space is called *hyperspace*. The principal forms of hyperspace are these:—

(1) *Space more than triply infinite*, or, in familiar language, having more than three dimensions. In such a space four or more lines, each perpendicular to all the others, could pass through a point. Of course this is inconceivable, but quite self-consistent.

(2) *Curved or non-homoloidal space*, which may be *elliptic* or *hyperbolic*:

(a) *Elliptic space*: that in which two parallel straight lines intersect when produced to a certain distance.

(b) *Hyperbolic space*: that in which two such lines diverge from each other. (S.N.)

Space-perception: Ger. *Raumwahrnehmung*; Fr. *perception de l'espace*; Ital. *percezione di spazio*. Cognition of extension so far as it does not involve conceptual process. 'Cognition of space' is a better term than 'space-perception.' See **EXTENSION**, and cf. **SPACE**.

Properly speaking, there is no perception of space considered as an individual unity boundless in extent and comprehending within it all the places and distances of the contents of the physical universe. This is a concept, not a percept. The same is true of the space of the Euclidean geometry and of the various kinds of space treated of in *metageometry*. (G.F.S., J.M.B.)

Many experiments have been performed upon various aspects of the problem, particularly the cognition of visual and tactual extent. See **DEPTH** (visual perception of), and **INDIRECT VISION**; and cf. **STATIC SENSE**, **EQUILIBRIUM**, **ILLUSIONS OF MOTION**, I, and **LABORATORY AND APPARATUS**, III, B, (a), (c). Pathological cases, of impaired or undeveloped cognition (notably cases of restoration to sight of those born blind), are also instructive.

Literature: see **EXTENSION** (and other topics cited); also **BIBLOG.** G, 2, v. (J.M.B.)

Space Sense: see **EXTENSION**, and **SPACE**; and cf. **SENSATION AND SENSE** (2).

Spacialization: Ger. *Raumlokalisation*; Fr. *spacialisation*; Ital. *spazializzazione*. Suggested for the external **LOCALIZATION** (q. v.) in space which is contrasted under that topic with the reference of a stimulation to a position on the periphery of the body. The term *localization* would then be restricted to this latter. (The French and

Italian equivalents are also suggested—with approval of TH F. and E.M.) (C.L.F.—J.M.B.)

Span of Consciousness: see **FIELD OF CONSCIOUSNESS**.

Spasm [Gr. *σπασμός*, cramp]: Ger. *Spasmus*, *spastischer Krampf*; Fr. *spasme*; Ital. *spasmo*. A convulsive, involuntary contraction of a muscle or set of muscles. A tonic spasm causes a more or less persistent contraction of the muscle, while if the contraction is intermittent it is termed *clonic*; the former are termed *cramps*, the latter *convulsions*.

Facial spasm ('tic convulsif') is due to lesions in the cortex or root-nucleus of the facial nerve, or in the fibres of the nerve itself. *Spasmus nictitans* or *spasmodic blinking* and *blepharo-spasm* affect the eyelids and face adjacent. *Bronchial spasm* is apparently a *vagus neurosis*. Spasms of other muscles occur as symptoms of a large range of nervous diseases.

Hemispasm is an epileptiform seizure confined to one side of the body.

Monospasm is a convulsive contraction of a single group of muscles resulting probably from a focal point of irritation in the central nervous system.

As examples of spasms may be mentioned the spasm of the pharynx in *hydrophobia*, of the diaphragm in *hiccup*, the various convulsions of an epileptic seizure, the paroxysms of *hysteria*, the inco-ordinated movements of *chorea*, *tremors*, and the like. See **EPILEPSY**, **HYSTERIA**, **TREMOR**, **MOVEMENT (disorders of)**, and **ATAXIA**. (H.H.—J.J.)

Special Creation Theory or Creationism (q. v. for foreign equivalents). The theory that biological species were created each 'after its kind' by a direct act of God, and not by a process of evolution or genetic **DESCENT** (q. v., doctrine of). (J.M.B., E.B.P.)

Special Terms (in logic): see **SYMBOLIC LOGIC**, ad fin.

Species (in biology) [Lat. *species*, kind]: Ger. *Art*; Fr. *espèce*; Ital. *specie*. A group of genetically related individuals, presenting fairly constant and distinctive heredity, and sufficiently alike to be included under one name. The adjective *specific*—belonging to a species—occurs in phrases such as *specific characters*, *interspecific sterility*, &c.

The conception of 'species' has been so revolutionized since the publication of Darwin's famous book on their origin, that it now bears little resemblance to the ideas about species prevalent before 1859. It is, indeed, scarcely possible in a few words to give a satisfactory definition of what is now

meant by the word species, since it involves our whole conception of the process of organic evolution. Whilst species were formerly held to be of fixed, if slightly modifiable, character, to be incapable of fertile intercrossing, and to have been separately created, they are now considered to have been evolved from pre-existing species by gradual modification, to have no absolutely fixed character, and to be by no means always sterile when crossed with each other. Organisms need not necessarily be alike to be of the same species; as, for instance, in the case of the alternation of unlike generations, or of sexual differences. Similarity (of the individuals of one sex) at some stage of their life-history, and 'blood relationship,' are the only essential common characters of the individuals of a species. Each of the characters of the individuals of a species may vary about a mean, no two individuals being exactly alike. The specific characters of an assemblage of individuals (species) are those which are most developed in the largest number of individuals. By these the species may be defined. (E.S.G.)

Linnaeus defined species in terms of creation: 'Species tot sunt diversae, quot diversae formae ab initio sunt creatae.' Cuvier accepted and widely promulgated this orthodox doctrine. Buffon and Lamarck contended for the transmutation of species, whereby the accepted dogma was rendered nugatory. The number of German species of hawkweed, according to one botanist, is some 300, according to another less than twenty. The term 'species' was introduced by Ray, and the binomial system of nomenclature now universally adopted is due to Linnaeus. See CLASSIFICATION (in biology), VARIETY, VARIATION, HEREDITY, and EVOLUTION.

Literature: LINNAEUS, *Philosophia Botanica*; DARWIN, *Origin of Species*; KERNER, *Gute u. schlechte Arten*; ROMANES, *Darwin and after Darwin*, ii; A. R. WALLACE, *Darwinism*; K. PEARSON, *Grammar of Sci.* (2nd ed., 1900). (C.L.L.M., E.S.G.)

Species (and **Specific Marks**, in logic). A relatively narrow class and the marks which belong to it. See LATIN AND SCHOLASTIC TERMINOLOGY, 4, 14, and cf. DEFINITION. (C.S.P.—J.M.B.)

Species considered as disjunctively co-ordinated under a genus are called 'disjunct.' See DISJUNCTIVE. (J.M.B.)

Specific: see SPECIES (in biology, and in logic).

Specific Energy of Nerves: Ger. *speci-*

fische Sinnesenergie, spezifische Energie der Nerven; Fr. *énergie spécifique des nerfs*; Ital. *energia specifica dei nervi*. (1) The theory that each sensory nerve and nerve-fibre, in whatever manner stimulated, gives rise in consciousness to a specific sensation, different from that produced by stimulation of any other. 'This function of the individual nerves, determined by their anatomical connections, is called their "specific energy"' (Landois and Stirling, *Human Physiol.*, 1891, 714). (E.B.T.)

(2) Specific energy, it is now thought, depends on the end-organ, together with (especially) the central connections in the cerebral cortex.

The doctrine of specific energy of nerves was enunciated by E. H. Weber, and especially elaborated by Johannes Müller (*Physiol.*, ii. 250, 1840). The doctrine in the form (2) can be easily demonstrated with the sensory nerves of sight, hearing, and touch, including temperature and possibly pain. Taste and smell present extreme mechanical difficulties to experimental demonstration of the law. Oehrwall's recent experiments on taste (*Skand. Arch. f. Physiol.*, 1890, ii. 1) point strongly to its application to this sense. (C.F.H.)

Literature: a full discussion is given by WUNDT, *Physiol. Psychol.* (4th ed.), i. 285, 323-32; EBBINGHAUS, *Psychol.*, 144 ff., and references; LEWES, *Physiol. of Common Life* (1860), chap. viii; and *Problems of Life and Mind*, i. 135 (1874); HORWICZ, *Psychol. Analyse* (1872), i. 108. (E.B.T.)

Specific Gravity: Ger. *spezifische Schwere* (or *Gewicht*), *Dichtigkeit*; Fr. *poids* (or *gravité*) *spécifique*; Ital. *gravità specifica*. The ratio of the weight of a body to the weight of an equal volume of water; now replaced by the word DENSITY (q.v.). (S.N.)

Specification [Lat. *species*, kind]: Ger. *Spezifikation* (Fries); Fr. *spécification*; Ital. *specificazione*. The act of making specific (1) by a new determination of a mental content or object, or (2) by the determination of a notion in a less general class or in an individual.

The first meaning is useful in connection with the growth and successive modifications of a mental content, each reappearance of the content being a new specification of it. This usage is due to Stout. Cf. DETERMINATION. The second is the more popular, and the meaning in logic. (J.M.B., G.F.S.)

Spectator: see PRODUCTION, and PRODUCER.

Spectre [Lat. *spectrum*, a vision]: Ger. *Gespernt*; Fr. *spectre*; Ital. *spettro*. A ghostly apparition.

As a factor in popular belief (folk-lore), spectres play an important part and are conceived as disembodied human spirits revisiting the scenes of their former existence, with kindly or malicious motives, or as impelled by some mysterious necessity. At times they are represented as speaking, more usually as indicating their wishes by gestures. See PHANTASM, and HALLUCINATIONS, and cf. TELEPATHY. (J.J.)

Spectro-photometry: see PHOTOMETRY.

Spectroscope: see LABORATORY AND APPARATUS, III, B, (a), (3).

Spectrum: Ger. *Spektrum*; Fr. *spectre*; Ital. *spettro*. The band of prismatic colours, or isolated bands of colour, observed when the radiation from a source of light (sun, arc light, ignited vapour in a gas flame, &c.) is passed through a prism or reflected from a diffraction grating. See COLOUR MIXTURE, COLOUR-BLINDNESS, and FRAUNHOFER LINES. (E.B.T.)

The 'emission' spectrum of a source radiating trains of waves of different periods is the name given the collection of waves when separated into trains, each of a definite period, in such a manner that each train is proceeding in a direction different from that of the others. If the radiation from a body emitting waves of all possible periods is allowed to fall upon a substance, part will in general be transmitted or reflected, and part absorbed. If the transmitted and reflected radiation is dispersed in the above manner, the name 'absorption' spectrum is applied to the trains of waves which are not transmitted or reflected; that is, to the radiation which is absorbed.

Spectrum analysis is the study of both the methods for the production of spectra and the results of the comparison of emission as well as absorption spectra.

Spectra are produced by prisms and gratings owing to the dispersion of waves of different periods; and the radiation is detected by various means—photographic, instrumental, visual, &c.—depending upon the period of the waves. It is found that solids emit continuous spectra, i. e. there are present in their radiation waves of all periods between certain limits; that gases when luminescent emit discontinuous spectra, i. e. there are present in their radiation only isolated trains of waves, thus giving bright 'lines'; that at

any definite temperature the emission and absorption spectra of any substance are identical in all respects, provided that the state of the body is dependent on its temperature alone, not on electrical or other conditions.

Literature: H. KAYSER, Spectralanalyse, in Winkelmann's Handb. d. Physik, ii. 1; LAN-DAUER, Spectral Analysis (Eng. trans.).

(J.S.A., C.L.F.)

Speculation [Lat. *speculari*, to view, contemplate]: Ger. *Spekulation*; Fr. *spéculation*; Ital. *speculazione*. (1) Meditation or reflection of the mind upon itself, or upon spiritual things.

The Greek *θεωπία* meant direct intuition (Schauen) of transcendent, which is not discursive; thus opposed to dialectic. (J.D.—K.G.)

(2) A form of theorizing which goes beyond verifiable observation and reflection, characterized by loose and venturesome hypotheses (popular use).

(3) The conclusion and completion of the movement of thought which apprehends the unity of categories in and through their opposition. It has this last and technical sense in the Hegelian philosophy. The understanding lays down propositions in an uncritical and dogmatic form; unaware of any relation between its propositions, it asserts each as ultimate in its isolation. The negative reason, or dialectic, reveals the essential self-contradiction and self-transcendence, the fluidity of all these fixed concepts. When made ultimate it leads to scepticism; but when used as a factor in developing a more comprehensive point of view and a conception from and within which both the previous isolated notions and their opposition can be explained, it passes into speculative reason. This, like the understanding, is positive, but it is a positive which manifests itself through a process of development, instead of being assumed as fixed (Hegel, *Logic*, § 82). See UNDERSTANDING, and REASON. Cf. Eisler, *Wörterb. d. philos. Begriffe*, 'Speculation,' for citations, meanings (1) and (3). (J.D.)

Speculation (commercial). The attempt to make money by foreseeing changes in the price of goods and securities; buying them, or the means of producing them, when they are cheap; selling them, or selling rights to have them delivered, when they are dear.

When the speculator really foresees the movements of the market he renders great public service. By withdrawing goods from the market when they are overabundant he

prevents waste; by placing them on the market when they are scarce he prevents famine. His personal profit represents but a small fraction of the gain to society. Similarly in the case of the speculator who buys labour, and sells the products of that labour.

If the speculator does not foresee the movements of the market, but takes random chances of gain or loss, speculation is pure gambling; and if he attempts to manipulate demand instead of anticipating it, the case is still worse. (A.T.H.)

A form of stock-gambling, which is also called speculation, is dealing in 'margins': the buying and selling of goods beyond the buyer's power to pay, without demanding the actual delivery of the goods (which indeed may not exist—as in the case of unripe crops), and with the expectation of selling the purchase at a higher price before the demand for payment is made. The profit is the 'margin' between the buying and the selling price.

(J.M.B., A.T.H.)

Speech (and its Defects) [AS. *spæcan*]: Ger. (*die verbale*) *Sprache*; Fr. (*la*) *parole*; Ital. (*la*) *parola*. That exercise of the LANGUAGE FUNCTION (q. v.) which employs the VOCAL ORGANS (q. v. for their anatomy and physiology). (J.M.B.)

I. *The factors of speech*. The processes concerned in normal speech are primarily of three types: (A) sensory, (B) motor, (C) intellectual or (mainly) associational.

(A) Speech involves the use of a sensory organ, by the stimulation of which an impression is carried to the mind of the person addressed. Normally, the eye and the ear are the senses thus used, but in blind deaf-mutes touch becomes the sole receptive speech process; while in the deaf the eye becomes the medium of other speech types than the usual ones of reading printed or written characters. The other senses do not present the easily recognizable variety of impressions, nor does our motor endowment contain the means of rapidly producing impressions capable of affecting them, both of which are requisite for a convenient mode of expression. While the mere existence of speech is conditioned upon the possibility of some form of sensory or receptive function, it involves as well a second element of interpretation: only when the sense impression which has first been seen or heard is interpreted, does it represent

a complete receptive factor of speech. We hear the sounds of a strange language, we see the printed characters of a Chinese book; but these sensory processes are not speech processes until we interpret what is spoken or written.

(B) On the motor or expressive side speech again involves a double process: (1) the ability to contract in regular co-ordination certain groups of muscles, for (2) the production of significant sounds.

[The nerve-fibre bundles pass down in the internal capsule from Broca's centre to nuclei of origin in the medulla and spinal cord for the motor nerves of the tongue, larynx, jaws, and lips, and muscles of respiration. (C.F.H.)]

The selection of the movements available for speech was determined by utility, i.e. variety, quickness and ease of production, and especially the readiness with which the resulting changes of position (articulation) may be perceived and distinguished, although these utilities are not consciously subserved in the evolution of speech. Among motor mechanisms the lips, tongue, and vocal cords are pre-eminent. In contrast with movements addressed to the eye, as in sign language, these are more fundamental and natural; they are always available by day and night, and whether the communicants are within sight of one another or not; the mechanism is capable of producing an endless variety of sounds, with which the analytic power of the ear keeps pace; and sounds pass readily from an immediate natural to an indirect symbolical meaning. The correlation with a sensory function, which guides and directs the results of muscular co-ordinations, is of fundamental importance alike for the comprehension of the nature and growth of normal speech and for that of speech defects.

(C) The importance of the associative factors arises primarily from the interpretative element in both receptive and expressive speech processes; but it acquires additional complication from the existence of several forms of the language function—reading and understanding, speaking, and writing—and the consequent association of each with the others. We may write by dictation what is addressed to the ear, or read aloud from the page as well as repeat vocally what we hear, or reproduce manually a set copy. These processes proceed respectively from ear to hand, from eye to voice, from ear to voice, and from eye to hand. The latter pair are

SPEECH AND ITS DEFECTS

relatively simple, and form an important factor in learning to speak and write; the former pair represent facilities which almost inevitably result from the associations built up in the acquisition of the four fundamental speech processes, but none the less represent additional association groups. Still further complications arise when the speech processes are carried on in several languages, with various degrees of fluency, i. e. of intimacy of association, between the sensory and motor processes involved.

The specific nature of these associations must be carefully noted. In the receptive processes it is the centring of a cluster of memory-images or dispositions about a particular sound addressed to the ear, or a combination of characters addressed to the eye; these may vary indefinitely in character, but they retain a sufficient nucleus of similarity in different individuals, and from time to time, to serve as a basis of connection between word and the object or idea named. The same idea may be aroused by hearing the word 'blue' spoken, by seeing it in print, or again, to one acquainted with German or French, by hearing or reading 'blau' or 'bleu'; and also by seeing the blue sky or a blue flag. That associations of a useful and complicated kind may occur without the medium of speech can hardly be doubted; and the existence of such non-verbal associations is significant in the analysis of speech defects. On the motor side the association is that between the idea and the motor images or dispositions accompanying the production of the sound in speaking, or of the manual movements in writing. These kinaesthetic associations are more difficult to realize independently; for the execution follows immediately upon the innervation, and the innervation upon the intention to speak. And yet movements here as elsewhere are guided by complicated sensations of position and contraction, in the absence of which the bond between the intention to speak, accompanied by a clear knowledge of what one wishes to say, and the placing of the vocal organs in the proper position to say it, is broken, and that without any paralysis or other impairment of the muscles involved. We remember how to speak, just as we remember how to walk, or to skate, or to perform an act of skill; when we forget these the proper association of sensory with motor elements fails. We may realize what we wish to do and what the result would be if accomplished, but fail to set the muscular

co-ordinations accurately enough to produce what is intended.

Together with the other language functions the speech processes may be conveniently presented in the following arrangement:—

LANG. FUNC.	RECEPTIVE.	EXPRESSIVE.
Primary	Understanding (by the ear) ¹	Speaking
Secondary	Intelligent Reading	Writing

In this scheme the following relations are important: (1) each expressive function depends upon and is closely related to a receptive function. The ear and the voice, the eye and the hand operate together. In this combination the receptive is earlier and conditions the expressive. The child learns to understand before he learns to speak, and he normally learns to speak because and so far as he learns to understand. Nature furnishes a convincing illustration of this genetic relation in the fact that deafness leads to dumbness (cf. DEAF-MUTISM). The higher animals acquire considerable facility in interpreting our speech sounds, but they do not speak. One may learn to read without knowing how to write, but one cannot normally learn to write without being able to read, i. e. to recognize and interpret what one writes. (2) The receptive functions cover a wider scope than the expressive ones. We understand many more words than we use; we recognize faults in pronunciation which we cannot correct, and so on. (3) The ear-voice mechanism is an earlier and simpler development than the eye-hand mechanism. All children by simple imitation learn to understand and speak, but it requires a special and somewhat elaborate training to acquire reading, and, in obedience to the former principles, a still more protracted training to learn to write.

The relations thus noted condition the extent and nature of the associations which for each individual represent his language functions. Whether impairment of one association group will bring with it impairment of another will depend upon the relative independence of organization of the two; such independence being a factor of the inherent relations between the language processes and also

¹ While three of these processes have received distinctive names, the most fundamental of all, by its very obviousness, has failed to be described by any other word than that which refers to the interpretation of a form of sense impression.

of individual training. A man of culture and large literary training may read and write as easily and as fluently as he understands and speaks, and with no reference to spoken language; but for a poorly educated person reading is a distinct translation into auditory symbols, while writing is hardly more than drawing; and such differences will be reflected in speech defects. Along with these differences should also be noted the varying prominence which visual and auditory and muscular processes occupy in different minds—eye-mindedness, ear-mindedness, motor-mindedness, &c. Cf. TYPE (mental).

It is also to be noted that the language processes in which there is no outward expression, or only a very suppressed expression, are significant in the conception of the factors involved. The name INTERNAL SPEECH (q. v.) is given to these, and they consist of reading to oneself and in formulating words for speech or thinking in verbal terms. Such processes are often but vaguely realized, and evade close examination, but their integrity is essential to a complete speech development, and their preservation in speech defects is often significant.

II. *Disorders of speech.* The complete act of speaking involves (a) the capacity to think or formulate ideas; (b) the ability to recall and construct the words which express the ideas; and (c) the actual articulation of conventional sounds. Receptive speech involves an impressibility of the ear or eye, a recognition of the particular sounds or symbols used, and an intelligence and training sufficient to appreciate their significance. If there is a defect in hearing or seeing, it may modify or interfere with normal speech processes, but it does so only secondarily, such defects being primarily of the ear and eye. If there is a defect in articulation due to partial paralysis or faulty structure of portions of the vocal mechanism, such defect interferes with perfect speech, but is not a true aphasia or disorder of speech, but a disorder of articulation. Again, any disorder of the intellect which makes speech impossible or incoherent is primarily mental and not specifically aphasic; the defective speech, or inability to speak, of an idiot or of a demented person is a part of his general mental deficiency. There are, however, certain nervous difficulties which affect speech, and certain faults of articulation, some of them of a composite character, which it is customary to consider in connection with true disorders of speech. We may thus

(following Séglas) distinguish (a) the *dyslogias* or disorders of intelligence which affect speech, (b) the *dysphasias* or true disorders of speech, and (c) the *dyslalias* or *dysarthrias*, i. e. difficulties of articulation.

[These three types of defect correspond to the three 'levels' of nervous process usually distinguished as 'first,' 'second,' and 'third' level. The lowest, or third, is purely sensori-motor, but its impairment may be sensory or central as well as purely articulatory—as is seen in verbal AMIMIA (q. v.) of central origin. (J.M.B.)]

(a) *Dyslogia.* There is a form of defect in children in which, without deafness and without paralysis, speech fails to appear; this is sometimes termed congenital aphasia. There is usually a good understanding for words, but the impulse to speak or the power to develop the motor speech centre is abnormally weak. Such cases often develop speech very late, and may retain marked articulatory defects. Apart from dementia and idiocy and general mental disorganization, there are several functional disorders characterized by absence of speech or defective speech which are partly of mental origin; these will be considered under functional aphasia. Cf. ALOGIA, APHASIA, CATAPHASIA, ECHOLALIA.

(b) *Dysphasia* is more commonly termed aphasia in the general sense of impairment of some one or more of the factors of speech, not due to intellectual defect nor to defect of the articulation or externalization of words. Such defects form the main subject of this article. Cf. APHASIA.

(c) *Dyslalia* or *dysarthria*, or defects in articulation, are of various kinds and affect different portions of the composite result. As the result of articulation is guided and corrected by the ear, any serious defect in hearing will affect articulation. The clearest example of this appears in the mutism that results from congenital or early deafness (cf. DEAF-MUTISM), and also in the faulty articulation and modulation of deaf persons who have been taught to speak by the guidance of kinaesthetic muscle sensations alone. Of defects of articulation due to specific motor disorders may be mentioned STUTTERING (q. v.), LALLING (q. v.), the characteristic defects of young children, APHONIA (q. v.) or difficulty in voicing the articulation, and various forms of special difficulties in connection with specific letters and sounds (cf. ANARTHRIA). See also AMIMIA.

III. *Aphasia: History.* The modern study

of aphasia—understood to comprise defects of the language functions as a whole, not merely verbal speech—began in 1861 with the memoir of Broca, which located the seat of the disorder in the third frontal convolution of the left hemisphere. There were earlier and disconnected attempts to study the pathology of speech by Bouilland (1825), Jackson (1829), Dax (1836), Lordat (1843); the speculations of Gall (died 1828) and others were also influential. To the motor aphasia of Broca (also termed aphemia), the conception of sensory aphasia was added by Wernicke in 1874; and the first comprehensive work on disorders of speech was that by Kussmaul (1877), in which the terms word-deafness, word-blindness, and other distinctions were first introduced. Following this came the remarkable researches of Charcot and his school. Since then the literature of aphasia has grown to unusual proportions, and a great variety of interpretations and classifications of aphasic defects has been introduced. Hypothetical diagrams to illustrate the relations of speech centres and their connections have been extensively employed by Wyllie, Elder, Lichtheim, Bernard, and Baldwin. Amongst the recent contributions have been the differentiation of cortical and subcortical aphasia, the controversies in regard to the existence and nature of transcortical or associational aphasia, in regard to the existence of a separate graphic centre, and in regard to the precise cortical localization of the auditory, visual, and motor speech areas. In the following exposition an attempt will be made to present the results which command general assent. (On the history see especially Collins, chap. ii, and Elder, Introduction, both as cited below.)

IV. *Classification and Analyses.* As aphasia appears as a symptom in various disorders, it becomes of the first importance to differentiate aphasic symptoms. The first step is readily taken by noting whether the defect consists in the impairment of the power to speak, to comprehend spoken language, to read, or to write. But this external distinction must be supplemented by a determination of the cause of the symptom. Such cause may be expressed in anatomical terms as due to the injury of a certain portion of the brain, or in psychological terms as due to the interference with the function of some one of the processes involved in speech. In the present state of knowledge it is necessary to supple-

ment each of these sources by constant reference to the other; and both must be interpreted in accordance with the facts of the normal development of speech. The distinction between motor and sensory aphasia is a fundamental one; the further division of these disorders is discussed below. Anatomically, aphasias may be classed as cortical when there is a lesion in the speech centres; as subcortical when there is a lesion in the lower centres or their connections; and as transcortical when there is a lesion in some of the associational fibre systems connecting cortical speech centres with one another. Such a classification is dependent upon clinical experience; it assumes a knowledge of what centres are involved in speech, their location, and that of the fibre-systems connecting them. While the knowledge thus required is only partially available, the definiteness of the resulting conception of aphasic disorders renders it a most serviceable classification.

[Transcortical, cortical, and subcortical correspond in order to dyslogia, dysphasia, and dyslalia, as given above. 'Cortical' is often used, however, to cover all cases except the 'subcortical.' (J.M.B.)]

The speech centres. The fundamental association of defects of speech is with lesions in the left hemisphere. The general sensory and motor areas of which the speech centres present specialized functions are present in both hemispheres, and it is with reference to these that the speech centres must be interpreted. There is thus a general centre for the visual interpretation of objects (occipital lobe, probably including internal surface near calcarine fissure); a special centre for the interpretation of words as read (that part of the inferior parietal convolution known as the angular gyrus); a general auditory centre for the interpretation of sounds (first and second temporal convolutions); a special centre for the understanding of spoken words (middle portion of first temporal convolution); a general psychomotor area for the expression of thought by movement (the Rolandic region, ascending frontal and ascending parietal convolutions); a special motor or kinaesthetic-motor speech centre (Broca's convolution, foot of the third frontal convolution); finally, a centre for the direction of hand-movements (a portion of the middle Rolandic area) and (admitted by some but denied by others) a special graphic centre (for writing, foot of second frontal convolution). See Fig. 1.

[The entire Rolandic region, called above the 'general psychomotor area,' is by many, following Bastian, held to be the centre for kinaesthetic sensations and ideas, the true motor or 'discharge' centres being considered subcortical. (J.M.B.)]

The location of the special speech centres in the left hemisphere is connected with the prevalence of right-handedness. In left-handed persons these centres are situated in the right hemisphere. The left hemisphere is regarded as containing the centres for the more highly specialized functions; among them, manual dexterity and articulation. The

Fig. 1. Diagram of speech centres (Elder). The circles indicate higher speech centres; the crosses indicate the higher auditory and visual sensory centres and the motor areas most closely connected with the movements involved in speech. A, auditory centre; B, psychomotor speech centre; C, visual centre; D, supposed psychomotor graphic centre; a', auditory nerve; b', nerve-fibres to muscles concerned in articulation; c', optic nerves; d', nerve-fibres to hand. [For other diagrams representing different views as to the exact localizations, the most recent literature should be consulted.—J.M.B.]

cortical centres for sight and hearing are concerned only with the interpretation of optical and auditory impressions, and their destruction produces neither blindness nor deafness (which are due to lesions in the subcortical centres or in the connections of the latter with their sense-organs), but a peculiar defect known as Mental BLINDNESS (q.v.) and Mental DEAFNESS (q.v.), in which, with vision and hearing intact, the sight or sound conveys no meaning. Word-blindness and word-deafness are similar but more limited defects of the visual and auditory word-centres (see below). A differentiation in regard to the motor centres is less clear. By some the motor speech centre is regarded as specifically

motor, i.e. as serving for the emission of the movements of articulation; while by others its function is regarded as more truly sensory (kinaesthetic), i.e. a centre for the storing of the sensations and images accompanying and guiding articulation. Both this and the supposed graphic centre form portions of the general motor area, the functions of which are subdivided into specialized regions in control of the movements of the hand, of the lips and tongue, &c. These several centres must not be considered as independent or autonomous; their intimate relations to one another must be clearly realized, and particularly the close association of all in vocalized speech. The special relation which obtains between hearing and speaking—and again between writing and reading—is of co-ordinate importance (cf. Figs. 2, 3, 4).

V. *Motor Aphasia.* (a) *Cortical:* the fundamental symptom is lesion in Broca's convolution; aphasia due to inability to articulate. This is not the result of any paralysis (although with a lesion in this area, owing to its proximity to the motor centres, some degree of paresis, hemiplegia, is frequently present), but is best interpreted as due to the loss of the kinaesthetic motor images which direct articulation. Along with this loss there is a loss of all speech processes which require the integrity of these kinaesthetic memories. Hence the motor aphasic is often unable to repeat words which he hears and understands, and is unable to read aloud the words which his eyes see. [He may, however, retain the purely imitative performance of both functions.—J.M.B.]

Moreover he is unable to write, because as a rule in writing there precedes and accompanies the actual manual execution certain articulatory images following upon the visual images of the letters formed, or, in case of writing from dictation, of the sounds heard (see Figs. 3 and 4). Even the power of understanding written and printed characters is likely to be interfered with because and in so far as these visual symbols achieve their interpretation by arousing, though inaudibly, the corresponding utterances. In brief, the analysis of speech factors (see above) indicates the two primary factors to be understanding of spoken words and their articulation, on the basis of directive kinaesthetic sensations. When the latter capacity is lost the former remains unaffected, but the secondary speech processes are affected in so far as they are dependent upon the directive sensations just

SPEECH AND ITS DEFECTS

Fig. 2. (After Pershing, with additions.)

Fig. 3. (After Pershing, with additions.)

Fig. 4. (After Pershing, with additions.)

In Figs. 2, 3, 4, the arrows show direction of impulses; *M* is the motor, *A* the auditory, *V* the visual speech centre; *I*, *I'*, *I''*, the ideational centres; *G*, the graphic centre; *a* indicates fibres from the ear to the auditory centre, *v* from the eye to the visual centre, *m* fibres to the organs of articulation, and *g* to the hand. Fig. 2 represents the utterance of a word corresponding to a visual idea; the impression reaches the visual centre, and from there, directly and by way of the auditory centre, the motor centre is incited to send out articulatory impulses. Fig. 3 illustrates reading aloud with understanding of what is said. The visual impressions reach the centre *V*; and the reader hears what he reads by way of the ear and the auditory centre; both centres are connected with the centres *I*, *I'*, *I''*, by means of which comprehension takes place; the constant direction of articulation in accordance with what is seen is also important. In silent reading the tracts *M m* and *a A* are not used, but the auditory centre is reinforced by the reflex impulses *M A*. Fig. 4 illustrates the

process of writing. The centres for ideas *I* (represented as single for the sake of simplicity) send impulses to *A* and to *M*, reviving memory of sound and utterance; *A* sends impulses to *M*, ensuring correct memory of utterance; *M* sends impulses to *V*, recalling the appearance of the words, and *V* to *G*, recalling memory of the hand movements. *G*, *g*, the outgoing impulses to the hand; *M G*, short cut for words written automatically when *V* and its connecting tracts are not used. In writing from copy the impressions enter directly at the centre *V*, and in writing to dictation at the centre *A*.

[Most of the diagrams, of which these may be taken as examples, are variations upon those of Lichtheim (work cited below).—J.M.B.]

mentioned. The determination of these directive sensations, and of their loss in cortical motor aphasia, thus becomes of great importance. The best test is the integrity of INTERNAL SPEECH (q.v.), of thinking in words. According to the analysis here followed, this power should be completely lost in complete cortical motor aphasia, and because of its loss the patient cannot speak, and concomitantly cannot write or even read. If he retained the internal motor images of spoken words, he should be able to indicate, e.g. by holding up the proper number of fingers, the number of syllables contained in a word which he understands when he hears it but cannot pronounce; this test (known as the Proust-Lichtheim test) in cases of true cortical motor aphasia cannot be met. Many writers regard this inability as the distinctive criterion of cortical motor aphasia, and the ability to meet this test as indicative of subcortical motor aphasia.

[This test should, however, be followed by the imitation test, the patient being instructed to repeat exactly questions addressed to him. The retention of this power shows the lesion to be restricted to the cortical area. This test is suggested by the fact that patients of this sort often spontaneously repeat questions addressed to them instead of answering them. (J.M.B.)]

It happens not infrequently that the motor aphasic retains the power of saying a few words or phrases of a reflex or of an emotional type. These he uses repeatedly and often inappropriately. He may say 'yes' or 'no,' 'good-morning' or 'how are you?' or utter meaningless sound or a conventional oath. This may be regarded as an indication that the cortical centre is not completely destroyed, or may be interpreted as a purely emotional expression, the use of which, like scowling or making a fist, this class of aphasics retain. In regard to writing, the

ability to sign one's name is oftenest retained, and this because the signature, unlike words in general, is a mere bit of manual execution, and does not tend to be mentally pronounced as do other written words. But the capacity to write from copy is present, and such copying is done in obedience to the established habit; print as well as script is copied as script. The copying process thus does not involve the kinaesthetic articulatory memories; it is called into action sufficiently by the visual stimuli [being a purely imitative sensori-motor process—J.M.B.].

It is, moreover, to be noted also that this form of cortical aphasia is often accompanied by a dyslexia (or difficulty in reading), which may be indicative of a partial involvement of the visual word-centres; and this condition when present will likewise affect the power to write. While the mental faculties are not obviously impaired, there is an indisposition to mental application; there may be a considerable amnesia and a diminished grasp of facts communicated during the aphasic condition. In recovery, or partial recovery from complete cortical motor aphasia, interesting symptoms are often observed; of these, paraphasia, or the wrong use of words, is characteristic. The most absurd substitutions of unrelated words may occur ('kittens' for 'stockings,' 'chickens' for 'sponge,' &c.); and the result of reading aloud is a confused mixture of correct and irrelevant words (see Collins, *ascited below*, 185 ff.). There are many other symptoms of this form of aphasia which are of variable occurrence and of doubtful interpretation, and which require the detailed description afforded them in medical literature.

(b) *Subcortical motor aphasia* is dependent upon a lesion in the fibre-system that leads from Broca's convolution to the subcortical centres and ganglia. Its characteristic is the inability to externalize speech, along with the integrity of the power to form words properly as a factor of internal language. The symptoms of this type of aphasia closely approximate to those of the cortical type; and until recent exact differentiations were introduced, the two forms were doubtless frequently confused. The main differentia are the retention of the ability to write, and the retention of the idea of the word (Proust-Lichtheim test as above described), both of which point to an integrity of the kinaesthetic memory images. In typical cases none of the other speech factors is affected, but the

loss of speech (and with it the inability to repeat from dictation, or to read aloud, both of which involve externalized speech) remains the sole difficulty. The interpretation of cases presenting more complex symptoms forms a significant portion of current discussions. The presence of some degree of paralysis and the more rapid assumption of spoken speech upon recovery are characteristics of the subcortical type of motor aphasia. [The imitation test is the proper one here, since this form of aphasia involves verbal amnesia.—J.M.B.].

VI. *Sensory Aphasia*. The characteristic loss in sensory aphasia is that of the comprehension of words heard or read; the most frequent concomitant symptoms are paraphasia and agraphia. It presents two varieties, according as the auditory or the visual centre is involved; these centres are independent, and the one may be affected with complete integrity of the other. So far as the memory images connected with these centres are utilized in other speech processes will such other processes be affected by injury to the sensory centre; internal language is more affected by loss of auditory than of visual word memories, because the primary revival of words is closely related to the fundamental auditory associations. Although many cases exhibit both auditory and visual defects, it seems best to consider the two classes separately.

(a) *Auditory Aphasia*. The characteristic symptom of cortical auditory aphasia is termed word-deafness, and consists in an inability to interpret words which are, however, distinctly heard. The ability to comprehend the meaning of other sounds than words may remain intact. Such cases of pure auditory word defect are uncommon, but they do occur, and their cortical localization is known (see above). The word-deafness may be incomplete; the patient may understand his own name or other familiar names, or again, he may recognize a few common words in simple sentences, and guess the meaning of the rest; he may retain the power to interpret one language, but not others, and so on. One who is word-deaf can obviously not write from dictation. Reading to one's self (internal reading) is apt to be disordered because and in so far as reading involves the transmission of impulses from the visual to or through the auditory area, in the revival of word-memories which is a part of such reading. Paralexia is thus a frequent symptom. As in speaking one

hears and understands the words he speaks, and thereby corrects any accidental *lapsus linguae*, the inability to understand words renders such directive and corrective aid impossible, and the result is a constant succession of *lapsus linguae* or paraphasia, which is the more marked on account of the loquacity often characteristic of this type of speech defect. If the recall of words is almost exclusively in auditory terms with the visual word memory weak, e. g. for illiterate persons, word-deafness may profoundly affect speech; other such patients prefer to answer in writing because of their more certain control over visual word memories. A defect of special interest in connection with word-deafness is musical deafness, tone-deafness, or amusia; this rarely occurs as a separate defect but often as a concomitant of word-deafness. The power to interpret and recognize tones and arias is lost in a way analogous to word-deafness. Some writers regard the evidence of such cases as indicative of a special musical centre (see Elder, as cited below, chap. x, and Baldwin, *Ment. Devel. in the Child and the Race*, chap. xiv. § 2, and citation from Starr on p. 71).

Another interesting symptom is verbal amnesia, or the inability to recall the sound of a word although the idea is in the mind. It is thus the converse of word-deafness; in the latter the sound does not arouse the idea, in the former the idea does not suggest the sound. Disorder of the auditory centre may involve both forms; and amnesias are characteristic of sensory as opposed to motor aphasias.

It should be emphasized that, clinically, auditory aphasia is a factor in a complex aphasic disturbance rather than an independent disorder; typical cases cited as auditory aphasia almost invariably involve disturbances in other sensory or motor speech processes.

(b) *Visual Aphasia*. The characteristic symptom of cortical visual aphasia is termed word-blindness or alexia, and consists in an inability to interpret written or printed symbols, which, however, the eyes distinctly see. Pure cases of this defect are rare (by some denied altogether), but its association with disease in the angular gyrus is well established. Its most frequent concomitant symptom is agraphia; while some degree of aphasia and word-deafness may be present. Its anatomical relations may bring about a right homonymous HEMIANOPSIA (q. v.), or

inability to see objects in the right halves of the visual fields. This is explained by the fact that the fibres near and subjacent to the left angular gyrus are connected with the left half of the retina in the *right* visual field. See LOCALIZATION (cerebral), and VISION (Fig. 7). When the lesion is strictly limited to the visual word-centre, hemianopsia is not present; but it is a frequent symptom because of the frequent involvement of fibres to the true visual area (half-vision centres). In the most typical cases of visual aphasia the interpretation of visual signs other than words—money, cards, chess, figures, &c.—is intact. Objects are recognized, and their uses indicated; such indication being obtainable by indirect means when speech is affected. Sometimes letters or even syllables may be recognized individually, but words remain unreadable. Such variations represent differences in degree of the defect and may reflect the mode of acquisition of verbal memories. Similarly cases of blindness to words in one language but not another (sometimes) occur, and some degree of object-blindness (see ASEMIA, also MIND-BLINDNESS) may be present with it; i. e. the memory for form and colour, for faces and distinctive features of persons and things, may also be affected. The common retention of the power to read one's name has already been noted; and in cases of partial visual aphasia portions of sentences may be read and the remainder guessed from the context, but always with hesitation and uncertainty. The ability to read numbers is quite commonly retained.

In complete visual aphasia the power to write is lost because that power is so largely dependent on visual factors; and of course such patients could not read what they have written if they could write. Writing is possible in dependence upon the kinaesthetic sensations accompanying the movements of the fingers in guiding the pen; hence if the patient's hand be slowly guided and the letters formed for him he may be taught to write, as the blind write, by dependence upon motor memories. On the other hand, writing or print may be copied, but the process is a purely imitative one; print is copied as print, and the handwriting is reproduced much as a forger would do it.

A related symptom to word-blindness, and one which frequently accompanies it, is inability to name an object when seen; e. g. a knife when seen cannot be called by its name, although the patient may say it is 'something

to cut with.' On the other hand, objects which appeal strongly to other senses as well as to sight, are more apt to be named readily; while names appealing directly to auditory or kinaesthetic sensations remain unaffected. This symptom has been termed optic aphasia (Freund), and has been regarded as indicative of a special naming centre (Broadbent, Mills). There is also an amnesic defect, a psychic blindness for words, in which the patient is able to read letters and words, but does not understand them when read; he hears and understands spoken words, but does not realize that the words he hears are the same as those he reads or copies.

Subcortical forms of auditory and visual aphasia have been described, although pure and definite cases and cases connected with consistent pathological findings are very uncommon. In the visual subcortical form an important characteristic is the retention of spontaneous writing and of writing from dictation. The main loss is that of the power to read because the impressions do not reach the visual word-interpreting centre. That this centre is intact may be indicated by the ability to trace letters with the fingers, and again by the power to spell. Copying is done literally, as in drawing, and not in free handwriting. Hemianopsia is generally present. More complex cases, in which the lesion encroaches upon the angular gyrus, or is accompanied by irregularities in other speech processes, are described in the literature. Still less frequent are pure cases of subcortical auditory aphasia. Its differentia from the cortical defect are the preservation of spontaneous speech, the absence of any verbal amnesia, and the patient's ability to read aloud, to write, to copy, and to read what he and others have written (cf. the diagrams).

VII. *Other disorders of speech and kindred defects.* It remains to consider (a) transcortical forms of aphasia, (b) functional aphasia, (c) complex forms, and (d) related disorders.

(a) The conception of a transcortical aphasia (also termed associative and conduction aphasia—*Leitungsaphasie* of Wernicke, and *interpictorial* of Wyllie) arises from the consideration of the results of a lesion in the associative fibre-systems connecting the speech centres with one another. The clinical existence of such cases, the determination of the symptoms in differentiation from those of other speech defects, and the

localization of a limited injury (not involving the speech centres) in post-mortem examination, are all matters of doubt and of difference of opinion. The clearest case seems to be that of a lesion between the auditory and the motor speech centre, such lesion affecting the fibres passing under the Sylvian fissure, or in the island of Reil; the symptoms are the inability to talk correctly, paraphasia, but without word-deafness, or deficiency in speech, and indeed without complete incapacity of any speech process. The auditory and motor centres are intact, but the destruction of the bond between them introduces defective performance of speaking and possibly of writing. It is possible to deduce the effects of a loss of connection between visual and auditory, between visual and motor centres, and so on; but it is rarely, if at all, possible to substantiate such defects along with the functional integrity of the centres concerned.

In many diagrams a separate ideational or apperceptive centre is posited which is in connection with the several speech centres. An interference with the connection of the auditory and ideational centre would produce a condition termed *suprapictorial auditory aphasia* by Wyllie and Elder; the symptoms of such defect are the inability to understand what is heard (and secondarily what is read; Wernicke and Lichtheim), but the retention of the ability to repeat what is heard, and to read aloud, though both without understanding; likewise, the ability to write, though mechanically, and a certain degree of error in all these processes. [That is, the mimetic, imitative, or 'third level sensori-motor' speech processes remain intact.—J.M.B.] Similar defects traceable to interference between the visual or the motor and the ideational centre have been described, but their differentiation from other forms of aphasia is difficult.

(b) There are many functional disturbances of speech presenting symptoms analogous to those described, differing only in their evanescent character, and having interesting stages of progress in recovery. A temporary inflammation, compression, or congestion (see aetiology below) may produce evanescent symptoms of organic aphasia. Aphasic disturbances due to poisoning (toxaemia) or infectious fevers present differences of origin and progress, but require no separate description.

Among functional nervous disorders, Hysteria (q. v.) presents peculiar speech defects. Hysterical aphonia is the most common of these, and consists in inability to approximate

the vocal chords and hence to speak loudly. Hysterical mutism, unlike the former, is a true speech disorder which renders the patient absolutely mute, although its hysterical nature is revealed by the anxiety to speak, fluency in writing, and the presence of hysterical stigmata. Stuttering and stammering, a defective memory for words, confusion in pronunciation and writing, are examples of speech defects, characteristic of periodic nervous affections, such as migraine, and of weakened conditions of the nervous system, such as neurasthenia, exhaustion, &c. Aphasic symptoms are apt to appear in epilepsy and in various forms of insanity (see Wyllie, as below, chap. xiv).

(c) It has been repeatedly implied that a compound injury to several speech centres is a common occurrence. Such cases may be termed complex aphasia; a very frequent form is a compound sensory aphasia involving the auditory and visual speech centres. Those who hold to a special graphic centre must admit its frequent involvement in connection with articulatory motor aphasia. In such cases the symptoms include the combination of symptoms of both disorders and occasionally additional difficulties. Cases of total aphasia are those involving all the speech centres, although not necessarily a complete loss of the several functions (a good case is given by Collins, as below, chap. vii). Many cases of compound aphasia are due to interference with the function of the Sylvian artery which supplies the speech areas with blood.

(d) The existence and nature of graphic-motor aphasia or agraphia demand special notice. The relations of writing to, and in part its dependence upon, the other speech factors, particularly articulation, the guidance of writing by vision, the tendency of words to be internally perceived in auditory terms, have been noticed above; these relations help to explain why agraphia is a common symptom in visual and auditory defects, and an almost constant one in cortical motor aphasia. Agraphia as an induced or concomitant symptom of speech defects is thus fully recognized. Does it, however, occur as a result of injury to a specific graphic centre? If so, how can such agraphia (which may be termed cortical graphomotor aphasia) be differentiated from other forms of agraphia? And what theoretical considerations favour the existence of such a centre? In reply it must be noted that unambiguous cases of inability to write with the right hand, with

retention of power to perform other movements, and with no other speech defect, and in turn associated with a sharply localized pathological finding, do not exist. The existence of cortical motor aphasia, even when strictly confined to the convolution of Broca, without agraphia, is disputed; but the fact that in recovery from such aphasia, agraphia may persist after the aphasia disappears is admitted. This may be interpreted as due to lesion in the association-fibre system between the motor articulatory and the graphomotor centre, but, like all such evidence, has been differently construed. That the graphic centre is not pathologically separable from the centres for the hand seems established. As to symptoms, the chief point to be noted relates to the characteristics of the writing, whether lost to the right hand only, whether the left hand in writing reproduces the characteristic handwriting or simply writes under purely visual guidance, and whether there are errors of writing, and of what character. On the basis of such distinctions attempts have been made to differentiate a true graphic-motor aphasia. There seems considerable reason to suppose, in the left hemisphere, a function connected with writing which is not present in the right hemisphere. For while writing, like drawing, is closely dependent upon visual images, the fluency and characteristic appearance of one's handwriting involves an additional kinaesthetic factor. Ordinarily these two factors are inseparable, and the dominance of the visual factor may obscure the other. The writing of the congenitally blind is in terms of the kinaesthetic factor, and a case of agraphia in such a person might be instructive. The differences and resemblances between writing with the right hand and with the left have also been regarded as significant in this respect; the similarity for those who can write with both hands is regarded as due not to visual control, but to the single graphic centre. The tendency for some persons, when writing with the left hand, to produce MIRROR-WRITING (q. v.) has also been interpreted as the result of the kinaesthetic impulse originating in the graphic centre (see Elder, as below, chap. ix). Cf. HAND-WRITING.

A peculiar speech defect has been described under the term dyslexia, which is akin to word-blindness, but differs from it in that the patient can read and understand, but for a brief period only; he quickly loses the power, but after a rest regains it. The defect

may extend to the interpretation of other visual symbols, being a form of mental blindness, and may be interpreted without regarding it as a distinctive disorder of speech.

The close relation of the specific speech centres to the more general sensory and motor centres results in the occurrence of many general defects along with aphasic disorders; and as a rule such occurrence is a mark of more extended and serious injury, and may affect the general intelligence. A more general auditory defect than word-deafness may extend to music, and to the interpretation of ordinary sounds, and thus constitute mental DEAFNESS (q. v.). The fact that so large a portion of perception is in visual terms gives unusual prominence to mental BLINDNESS (q. v.). It is important to test whether the blindness extends to the perception of numbers, of the meaning of cards and other objects used in games, to the recognition of the common objects on the table and about the room, to the signs whereby one finds one's way, and so on. There is often a partial and curiously limited object blindness, which requires for its interpretation a knowledge of the patient's normal habits of acquisition. When the defect is a very general one, so that no signs, conventional and others, are interpreted, the defect is termed ASEMIA (q. v.) or asymbolia. On the motor side the loss of articulate speech usually leaves the patient his command over gestures and other signs; when this is lost the condition is termed amimia; or when such gestures are confused, paramimia. The inability to handle familiar objects properly is similarly termed APRAXIA (q. v.). It is by some regarded as a general motor and sensory defect, of which similar defects just noted are special instances; i. e. it involves an inability to recognize objects, to whatever senses they present themselves, and to use them under guidance of the sensations which their manipulation would ordinarily arouse.

Throughout this presentation the speech defects of normal persons have alone been considered. It is obvious that the speech processes of a deaf-mute present important variations from the normal type. Carefully devised tests of their speech processes and the study of speech defects in such persons may contribute considerably to the illumination of doubtful points in this field. A case of aphasia in a deaf-mute is cited by Elder, as below, 233.

VIII. *Aetiology and diagnosis.* The organic

and the functional or dynamic aphasias are connected with quite distinct disorders. The latter occur in connection with such neuroses as epilepsy, neurasthenia, hysteria, and migraine; and again with toxic disturbances, such as uraemia, diabetes, and gout, and in poisoning by alcohol, santonin, tobacco, and other substances. The inability to name objects, the frequent speaking of wrong words, paraphasia, characteristic of migraine, and indeed of other nervous conditions and states of exhaustion, may serve to illustrate the slighter forms of functional aphasic defect.

The most frequent cause of aphasic symptoms is cerebral apoplexy, which occurs usually in maturity and advanced age. Any condition which produces pressure or irritation of the speech areas, such as abscess, tumour, and direct injury, may induce aphasia. The pathological growth is often confined to a sharply localized area, and gives rise to precise aphasic symptoms; the sudden onset of the attack, the nature of the partial recovery as the clot is absorbed, the interruption of blood supply to certain centres, may be definitely reflected in the combination of resulting aphasic symptoms. The fact that nearly all the convulsions connected with special functions receive their blood supply from the middle cerebral or Sylvian artery accounts in part for the frequency with which various forms of aphasia concur in the same patient.

It is evident that a careful differential diagnosis is often imperative to determine the nature and seat of aphasic disorders. A typical enumeration of tests for this purpose is given by Elder as follows: Can the patient hear (1) sounds of any kind, (2) words spoken; (3) can he understand spoken words; can he see (4) objects, (5) printed or written words; (6) can he understand them; (7) can he speak voluntarily; (8) can he repeat words; (9) can he read aloud; can he write (10) voluntarily, and (11) from dictation; (12) can he copy, and how? Subsidiary tests are the ability to read silently and to indicate the number of syllables contained in a word. As types of such diagnosis, may be mentioned that affirmative answers to 2, 3, 5, and 6, and negative answers to 7, 8, 9, 10, 11, 12, indicates cortical motor aphasia; affirmative answers to 2, 3, 5, 6, 10, 11, 12, and negative answers to 7, 8, 9, subcortical motor aphasia; affirmative answers to 5, 7, 10, and negative answers to 2, 3, 6, 8, 9, 11, 12, auditory cortical aphasia; affirmative answers to 2, 3, 7, 8, and negative answers to 5, 6, 9, 10, 11, 12, cortical

sensory aphasia, and so on. The transcortical varieties and other forms not clearly represented in clinical experience may be readily illustrated by the replies to these questions and by corresponding diagrams. Thus transcortical motor aphasia involves affirmative answers to 2, 3, 5, 6, 8, 9, 11, and negative answers to 7, 10, 12. It must be added, however, that not all of these differentia command equal importance or receive common interpretation at the hands of different writers.

NATIVISM AND EMPIRICISM, PSYCHOLOGY, SOCIOLOGY, UNIVERSAL POSTULATE, EVOLUTION, and UNKNOWNABLE. See also GHOST THEORY, PLAY, and ART. An epitome of the synthetic philosophy has been published by Collins. (J.M.B.)

Spener: see PIETISM.

Sperm [Gr. σπέρμα, seed]: Ger. *Samen*; Fr. *sperme*; Ital. *sperma*. Seminal fluid; the liquid secreted by the male genital apparatus.

In man it consists of spermatozoa from the testes, and secretions from accessory parts, chiefly the seminal vesicles and prostate gland. (C.S.M.)

Spermatogenesis [Gr. σπέρμα, seed, + γένεσις, origin]: Ger. *Samenbildung*; Fr. *spermatogenèse*; Ital. *spermatogenesi*. The production or development of male elements or spermatozoa.

The process comprises three stages: (1) the multiplication by ordinary CELL-DIVISION (q. v.) of the cell parents of the spermatozoa; the parent or mother-cells are also called spermatogonia (Ursamenzellen); (2) the REDUCTION DIVISION (q. v.) of a parent-cell, so as to form by two divisions four daughter-cells (spermatoblasts or spermatids), each with half the number of chromosomes, characteristic of the parent-cells of the species; (3) the gradual differentiation of the daughter-cells into spermatozoa by progressive changes in form or structure. See also SPERMATOZOON. That there are always four daughter-cells is probable, but the generalization has not yet sufficient observational basis. Cf. EMBRYOLOGY.

SPHYGMOGRAPH — SPINAL CORD

Sphygmograph: see LABORATORY AND APPARATUS, III, B.

Spinal Cord: Ger. *Rückenmark*; Fr. *moelle épinière*; Ital. *midolla, midolla spinale*. The least altered portion of the medullary tube, extending throughout almost the entire length of the trunk to the lower limit of the medulla oblongata, a point usually coinciding with the lower opening of the cranium.

The cord is usually enclosed in the vertebral canal of the backbone. The spinal cord communicates with the body at large by means of nerves, whose roots form a dorsal and a ventral series. The ventral nerve-roots are composed of fibres, which arise as neurites of cells in the ventral cornua and pass continuously to the muscles or other kinesodic structures. The fibres of the dorsal roots nearly all arise in the nerve-cells of the spinal ganglia and send their neurites centrally into the spinal cord, while their dendrites are produced as sensory nerve-fibres. Cf. WALLER'S LAW. The distinction between the dorsal nerves as sensory and the ventral as motor constitutes Bell's Law (1811). See NERVOUS SYSTEM (*Nerves*), and DEGENERATION (*nervous*).

On account of the greater nervous supply required by the segments of the cord innervating the limbs, these portions (intumescencia cervicalis et lumbalis) are greatly enlarged. To how great an extent the segmentation of the cord is due to the vertebral arrangement is uncertain. The spinal nerve-roots are plainly segmentally arranged; their central connections within the spinal cord are more obscurely so; and the cutaneous areas corresponding to these medullary segments do not agree with those of the root segments.

The original tubular character of the cord is maintained during life, the original cavity persisting as the *canalis centralis*. See NERVOUS SYSTEM (Histology). The topography of the cord may be gathered from Plate A (Spinal Cord), Fig. 1.

It should be added that the grey matter between the dorsal and ventral horns contains the centres for visceral reflexes connected with the sympathetic system. Afferent visceral impulses probably terminate in Clarke's column, while efferent impulses arise from cells of the lateral horn, paracentral nucleus, and intermediate zone (Onuf and Collins).

The longitudinal tracts which clothe the grey matter are massed, according to function and source, into columns or fasciculi, while the grey matter is aggregated into cornua con-

nected by the dorsal and ventral commissures respectively.

Upon the relations of the spinal nerves, cf. NERVOUS SYSTEM (Spinal Nerves). The dorsal root-fibres divide, after entering the cord, into ascending and descending branches, from each of which collaterals arise and pass to various regions of the cord. The best known relations are represented in Plate A, Fig. 1. Cf. also the accompanying figure from Kölliker. The sensory fibres traverse the cord for a longer or shorter distance, and then in many cases communicate with dendrites of cells whose neurites pass towards the brain as

Fig. 1. A, Direct reflex path. *sg*, spinal ganglion; *sa* and *sa'*, ascending and descending branches of root-fibres; *sc*, collateral; *m*, motor neuron; *mw*, motor root-fibre.

B, Indirect reflex path. *sz*, intercalary, or column cell; *vsf*, neurite of *sz*; *c*, collateral from *vsf*.

secondary sensory tracts. Others send collaterals directly to the ventral cornu cells, thus forming the direct reflex arc. The direct reflex arc is illustrated by Figs. 2 and 3 (after Cajal). The indirect reflex path is illustrated in Fig. 1, B.

Impulses entering the dorsal roots reach the cortex mainly in two ways: (1) by means of collaterals, which communicate with ascending fibres of the lateral columns of the opposite side; (2) by direct prolongations of the root-fibres, which enter the columns of Burdach and Goll. The latter terminate in the nuclei of the funiculus gracilis and cuneatus of the medulla, and here enter into relation with a secondary system, the lemniscus. These fibres cross in the medulla, and, like the others, reach the cortex of the opposite side.

The fibres of the motor columns, on the other hand, originate in cells of the cortex in the motor areas. In part they cross in the decussation of the pyramids in the medulla and

SPINAL CORD

enter the opposite lateral pyramids. Others descend uncrossed in the ventral pyramids. The dendrites of the motor cells in the ventral cornua are associated with the arborizations of the fibres from the pyramidal columns. In the case of the lateral pyramids the association is with the cells of the same side, while the ventral pyramidal fibres cross in the ventral commissure. Thus we see that, as all sensory impressions cross before reaching the brain, and there excite the cortex of the opposite side, so all motor stimuli originating in the cortex emerge from the ventral roots of the spinal cord on the opposite side.

The fibres which collect in Clarke's columns and subsequently enter the lateral cerebellar columns seem to have a relation to the function of co-ordination of motion.

The columns of white matter undoubtedly constitute the main paths of conduction in the cord, but the grey matter is coming to be regarded as also playing a very important part.

It contains, besides the nerve-cells, a dense mesh of finest fibrils derived from collaterals from both ascending and descending fibres. These, besides providing for the spinal reflexes, undoubtedly play some part in the transference of stimuli. See SUMMATION.

The accompanying diagram (Fig. 4) represents the course pursued by the sensory and motor stimuli to and from the cortex, as well as the associational and commissural fibres of the latter. See ASSOCIATION FIBRES.

The various tracts of the cord are intimately bound together by innumerable collaterals, and their analysis is a matter of extreme difficulty. An important aid in this analysis is the fact that in foetal life the fibres of the sensory columns become medullated before the motor, so that at this stage their separation is easy. Our most exact knowledge, however, has been obtained by the methods of degeneration. See NEUROLOGY (Technology).

Hemisection of the cord destroys the skin

Fig. 2. Diagrammatic transection of the spinal cord. Arrows represent the course of the stimulus from the sensory areas of the skin to the dorsal cornua via the spinal ganglion (*gg*), and by way of the motor root to the muscle plates (*m.p.*).

Fig. 3. Transection of the spinal cord of the chick, illustrating the relations of the spinal nerves.

SPINAL CORD

sensation of the opposite half of the body as a result of the decussation of the secondary tract fibres in the ventral commissure of the cord and the raphe of the medulla. Disease of the pyramidal tracts disturbs voluntary motion and produces tonic contractions. Injury to the dorsal root-fibres interferes with skin sensation, while disease of the secondary sensory tracts may leave the skin sensation nearly intact, but impairs the muscular sense.

Fig. 4*. (See the preceding page.)

Respecting the conductivity and other properties of the cord, as investigated by the electrical method, it is found that cortical excitation produces galvanic excitation in the cord, and such excitation is to a certain extent localizable. The electrical effects following corona radiata excitation are only half those following cortical stimulation. The normal discharge is unilateral, and the limitation to one side is more perfect when the corona is stimulated than when the stimulus is cortical. The spread of impulses from path to path is greater in the dorsal columns in the ascending direction, and in the lateral column in the descending. The direct path of afferent impulses is localized in the dorsal column of the

same side. The indirect paths are in the dorsal columns of the opposite side and in the lateral column of the same side as the excited nerve.

The histogenesis of the cord is essentially the same as that of the brain; the neuroblasts arise as free cells among the spongioblasts of the medullary epithelium and develop processes from either pole. The neurites of the ventral cornu cells emerge to form the ventral root-fibres.

Among lower animals the spinal cord of *Amphioxus* presents an exception, in that the cavity remains a vertical slit: see Fig. 3, Plate A (Spinal Cord). The supporting material is not differentiated beyond the development of the original endyma. The nerve-cells retain their position near the ventricle. It is supposed that the homologues of the spinal ganglia remain unseparated from the cord. Remarkable colossal cells, the significance of which is doubtful, also occur. In most aquatic vertebrates a set of large fibres (Mauthner's or Müller's fibres) run the entire length of the spinal cord, and are associated in the medulla with the acoustic tracts. They seem to be concerned with equilibrium in a fluid medium. In all vertebrates (but more highly developed in lower forms) there is a peculiar rod-like fibre running through the ventricular cavity of the brain and spinal cord from the roof of the mid-brain to the lower end of the *canalis spinalis*, known as Reissner's fibre. It is formed by the fusion of axis cylinders from very large cells in the roof of the *mesencephalon* and also in the caudal end of the spinal cord (Sargent), and it gives off fibrils to the grey matter of the spinal cord. Its function seems to be to provide a direct connection between the visual reflex centres and the body musculature. In the electrical fishes specially modified cells occur in the dorsal regions which supply the electric nerves. See ELECTRIC ORGANS.

In embryos and lowest vertebrates the support of the myelonic tissue is entirely afforded by the epithelial layer of the ventricle (spongioblasts). It is still uncertain whether the neuroglia of the adult cord is derived solely from this source. In disease the neuroglia increases in much the same way as in the brain.

Spinoza, Baruch (or Benedict) de. (1632-77.) Born at Amsterdam, of Jewish parents, he received a good education, with a view to becoming a Jewish rabbi, ending with the Old Testament, the Talmud and commentaries, and the scholastic philosophers; became sceptical of the past, and strongly inclined towards the Cartesian philosophy. Discarded both Judaism and Christianity, and embraced a pantheistic conception of the world. Expelled from the synagogue at

Amsterdam, he wrote a protest against his anathema, and changed his name to Benedict. Secluded himself, to avoid persecution, near Amsterdam, 1656-61. Resided in Rynsburg until 1664, in Voorberg until 1669, in Scheveningen 1671, until his death. He was never married. See topics cited under SPINOZISM.

Spinozism: Ger. *Spinozismus*; Fr. *Spinozisme*; Ital. *Spinozismo*. The philosophy of Spinoza, also philosophy of the type of Spinoza's. A notable exposition is Pollock, *Spinoza, his Life and Philosophy* (2nd ed., 1899). See METAPHYSICS, PHILOSOPHY, IDEALISM, and PANTHEISM. (J.M.B.)

Spirit (and Spiritualism) [Lat. *spiritus*, from *spirare*, to breathe]: Ger. *Geist*; Fr. *esprit*; Ital. *spirito*. I. Common to all meanings of 'spirit' is the conception of that which is conscious. Consciousness itself is not conceived as *being* spirit, but as being an attribute of it; so that spirit is conceived as something capable of existing, even when it is not conscious. On the other hand, there is no positive conception of *what* this permanent element in spirit is; it is only conceived abstractly as *that* (whatever it may be) which is the substance or subject of consciousness, and negatively as not identical with any known quale: e.g. even those who hold that consciousness is an attribute of material substance would not therefore say that matter was spirit, but only that there was no such thing as spirit. Hence:

(1) 'Spirit' and 'mind' may be used synonymously to denote merely this conception, without any implication as to the kind of consciousness, if any, possessed by the subject in question. It is mainly in this sense that all existents are commonly divided into 'spiritual' or 'mental' on the one hand, and 'material' on the other.

But (2) by 'a spirit' or 'mind' is meant any collection of spiritual existents which are bound together by the relations constituting personal identity. Hence 'spirit' and 'mind' themselves sometimes imply personal identity, i.e. exclude any subject of consciousness which is not either a spirit or part of a spirit. 'Soul' always thus implies personal identity.

(3) 'Spirit' may be used, in distinction from 'mind,' to denote exclusively the subject of some particular form of consciousness, with an implication that such form is 'higher' or better than others. Thus:

(a) A mind may deserve to be called

a spirit only if, either with or without other forms of consciousness, it possesses 'reason' and deliberate choice. 'Reason,' as thus defining spirit, is never understood in a purely psychological sense, but always as implying that some at least of the objects cognized by it are true.

(b) 'Spirit' may denote a subject, whose only cognitive form of consciousness is 'reason,' in that sense in which 'reason' is incapable of error. It may be used in this sense either with or without the implication of personal identity.

(c) It may denote a subject capable only of some form or forms of consciousness, conceived to be perfect, and hence different from and better than any known to us.

Cf. MIND, SOUL, NOUS, PSYCHE, and PNEUMA.

II. (a) 'Spiritualism' is a less common synonym for Idealism, in the sense in which that word denotes the metaphysical doctrine that nothing but spirit exists. It generally implies both:

(1) That spirit exists only in the form of one or more spirits, i.e. involves personal identity; and

(2) That all spirit is perfect, and hence is of the nature specified above either under (b) or (c).

(b) SPIRITISM (q. v.).

In Plato and Aristotle the equivalents of 'spirit' are *νοῦς* and *ψυχή*. *Νοῦς* denotes reason, or its subject, conceived as incapable of error, and does not imply personal identity. *Ψυχή* in Plato denotes the subject of consciousness, in the widest sense; but is conceived, when free from the body, to possess no faculty but *νοῦς*. Aristotle appears to include under the word the lower forms of life also, without definitely implying that consciousness is necessary to them. *Ψυχή* generally involves personal identity. The first appearance of *πνεῦμα* (of which the Latin translation *spiritus* gives us our word) as a regular equivalent of spirit seems to be due to the Stoics. Through their curious identification of every kind of spiritual with some kind of material phenomenon, *πνεῦμα*, which properly means 'wind,' came to stand for the vehicle of spiritual activities; and since, among the early Stoics, the active principle, whatever form it might take, was regarded as always *really* reason (*λόγος* or *νοῦς*), the special association of *πνεῦμα* with reason naturally followed. Thus in Philo it definitely stands for *νοῦς*, as opposed to the lower psychical functions, although among

some of the later Stoics *πνεῦμα* denotes these lower functions as opposed to *νοῦς*. The former usage prevailed, through its adoption in Christian terminology; and to Christianity, through the emphasis it threw on personal responsibility and immortality, is also due both the gradual inclusion of personal identity in the connotation of spirit, and the final reception of free will and some forms of emotion (as distinguished from the purely cognitive significance of *νοῦς*) among the higher or 'spiritual' forms of consciousness. In the last century there has been a tendency to revert to an impersonal conception of spirit, owing to the Kantian theory of a uniform contribution made by the mind to every object of knowledge. To make or to be this contribution seems to be very generally regarded as constituting the essence of spirit, its special relation to the subject of consciousness being very vaguely conceived. Spiritualism, which has come into use only in connection with the vogue given by the Kantian theory to the doctrine that everything is spiritual, frequently conveys this impersonal implication as to the nature of spirit. (G.E.M.)

Cf. also TERMINOLOGY, German, 'Seele and Geist,' and French, 'âme and esprit.'

In theology: the highest energy of a self-conscious being in the sphere of moral and religious knowledge and experience.

Spirit is conceived as an entity in religious thought, only when it is identified with the highest activity of self-conscious personality. In this sense perdurable individuality is predicated of it. The definition distinguishes spirit from soul, the highest activity of which is in the moral and religious sphere. Spirit is essentially a term of energy, and when applied to God involves the idea of divine energizing in the work of organizing and sustaining the higher manifestations of life. (A.T.O.)

Spiritism: Ger. *Spiritismus*; Fr. *spiritisme*; Ital. *spiritismo*. Belief that disembodied spirits exist and manifest themselves to men. Popularly called spiritualism.

The belief in the existence of miracles performed by unseen agencies is an ancient one, but the term spiritualism in its modern usage derives its importance from the manifestations which began in 1848 in the family of a Mrs. Fox, at Hydeville, N. Y., and from there quickly spread over the civilized world. Within a remarkably brief period spirit circles were established; journals and books on spiritualism were written and read; the

SPIRITISM

phenomena were enlarged and elaborated; investigations were instituted by scientific men; and the movement as a whole influenced, in an important way, the popular interest in and the conception of psychological topics. America and England remain the chief centres of spiritistic interest, although in France and Germany many believers in the doctrines of spiritism are to be found.

The earliest phenomena of spiritism assumed the form of raps or knockings, apparently of mysterious origin, but occurring only in the presence of the 'medium'; one knock was agreed to mean 'no,' and three knocks 'yes.' Questions could thus be asked and communications be established between the spirits and the living, through the 'medium.' Spirit circles consisted of gatherings of enthusiasts, often about a table, to whom, amid dim illumination and anxious expectation, such messages were revealed. The raps for 'yes' and 'no' were supplemented by using an alphabet and designating the letters; where-upon raps would occur at the desired letters, and more elaborate messages were spelt out. At this stage the influence of the studies of Animal Magnetism (q. v.) and HYPNOSIS (q. v.) reacted upon spiritualism, and developed a class of mediums who were put or put themselves into a TRANCE (q. v.) or sleep-waking state, in which they professed to be inspired by spirits and higher intelligences, and while thus inspired gave elaborate accounts of the spirit world. Entire volumes have been published purporting to be of such supernatural origin. (See PSYCHIC RESEARCH.) There came from 'animal magnetism' the conception of 'clairvoyance'—the power to see at great distances and in spite of ordinary obstacles. Mediums went into a clairvoyant trance and reported upon doings at remote places as well as from beyond this sphere. In the hands of professional mediums the phenomena increased in number and complexity. Spirit lights were seen; quasi-human voices were heard; writing was produced without human intervention; spirit photography showed the spirit-forms hovering about their living relatives; in materialization séances ghostly forms appeared with the features of departed friends; some mediums were lifted or 'levitated' in air; solids were passed through solids; cords and bands were unfastened by unseen hands; messages were written upon slates carefully tied together and removed from human interference; tables were tilted; mysterious messages were written by the

planchette; one's private and secret affairs were revealed by 'mediumistic' knowledge, and so on.

From a psychological point of view the phenomena fall into two classes. The one includes those which are mainly of physical origin, the alleged violation of physical laws. Essentially all of these phenomena have been reproduced by professional conjurers, while mediums have repeatedly been discovered in fraud in the production of their séances. Such phenomena illustrate the credulity of mankind, the absence of the critical faculty when the emotions and expectancy are involved, and emphasize the technical requirements necessary to discover such deception. The other group of phenomena involves some subconscious or automatic co-operation on the part of the subject. As in MUSCLE READING (q. v.) and AUTOMATIC WRITING (q. v.), so also in table turnings, in the use of the planchette, and in the production of the sympathetic atmosphere of the séance chamber, there is considerable unconscious co-operation and suggestion on the part of the subject, the precise nature of which has been more fully revealed by the experimental studies in hypnosis and HYSTERIA (q. v.).

So far as scientific investigations are concerned, it may be said that those which have been carefully conducted have served to indicate fraud, unconscious suggestion, and co-operation as sufficient explanations of what was presented; while the reported and more unusual phenomena failed to appear when rigid conditions were insisted upon. Although the philosophical doctrines connected with spiritualism occupy a secondary place in much of the literature of the subject, yet the anxiety to believe in and have evidence of an existence in a future life has been very influential in the propagation of the doctrine. To some, spiritism becomes a religious belief, and the material phenomena are of secondary importance.

Literature: CAPRON, Mod. Spiritualism (1855); R. HARE, Exper. Investigations of Spiritualistic Manifestations (1856); BINET, Alterations of Personality (Eng. trans.); A. R. WALLACE, Miracles and Mod. Spiritualism (1876); D. D. HOME, Lights and Shadows of Spiritualism (1877-8); JASTROW, Fact and Fable in Psychology (1900); Encyc. Brit. (9th ed.), Spiritualism; Rep. of the Seybert Comm. on Spiritualism; MORSELLI, Nuovo Misticismo in Psicologia (1896); WUNDT, Der Spiritismus. (J.J.)

Spirits (in theology). The term in the plural is used either for disembodied souls or for beings like the angels, who are self-conscious personal beings without corporeality.

The belief in spirits is all but universal, and has been a feature of all but the most undeveloped religions. In Judaism and Christianity the spiritual world includes the Infinite Spirit of God and finite created spirits. This latter class is distinguishable into human and superhuman. The latter are good or bad spirits, angels or devils. All spirits are conceived to be immortal. (A.T.O.)

Spiritual (and **Carnal**) [Lat. *carnalis*, fleshly]: Ger. *geistlich und fleischlich*; Fr. *spirituel et charnel*; Ital. *spirituale e carnale*. To be spiritual is to have a consciousness that is active and responsive in the sphere of the higher moral and religious ideas and motives, while to be carnal is to lack insight and responsiveness in this sphere and to react only to ideas and motives of sense and materiality.

This being true, it is intelligible that the Scriptures should identify the carnal mind with death, the spiritual with true life. To the only life that is of worth in the spiritual world the carnal mind is without response and practically dead. (A.T.O.)

Spirituality: Ger. *Geistlichkeit*; Fr. *spiritualité*; Ital. *spiritualità*. A quality called also spiritual-mindedness, by virtue of which its possessor is delicately responsive to spiritual ideas and relations and finds the things of the spirit the things of supreme value. (A.T.O.)

Spirometer [Lat. *spirare*, to breathe, + Gr. μέτρον, a measure]: Ger. *Athemmesser*; Fr. *spiromètre*; Ital. *spirometro*. An apparatus used to measure lung capacity in terms of the amount of air expelled from the lungs after the utmost inhalation. (J.M.B.)

Splanchnopleure (in embryology) [Gr. σπλάγχνα, viscera, + πλευρά, wall]: Ger. *Splanchnopleura*; Fr. *splanchnopleure*; Ital. *splanchnopleura*. The primitive wall of the digestive canal formed by the union of the endoderm with the inner or splanchnic leaf of the mesoderm.

The term was introduced by Michael Foster in 1875. It is often used incorrectly in Germany to designate the splanchnic mesoderm.

Literature: FOSTER and BALFOUR, Elements of Embryol.; F. M. BALFOUR, Compar. Embryol. (1881); MINOT, Human Embryol.; HAECKEL, Anthropogenie, 5th ed. (C.S.M.)

Spongioblast [Gr. σπογγίον, a little sponge, + βλαστός, a germ]: Ger. *Spongioblast*; Fr. *spongioblaste*; Ital. *spongioblasto*. An undifferentiated cell of the framework of the central nervous system; an immature spongiocyte. Cf. NEUROGLIA, and NERVOUS SYSTEM (Histology).

Most writers agree with His that the spongioblasts and the neuroblasts can be distinguished from each other from a very early period, perhaps even before the completion of the medullary tube. The most recent writers, however, assign the differentiation of the spongioblasts and neuroblasts to a later period of development, affirming that both may be derived from an indifferent type of cell.

Literature: W. HIS, Abhandl. d. k. sächs. Gesell. d. Wiss., xv (1889); and Arch. f. Anat. u. Physiol., Suppl. (1890); A. SCHAPER, Arch. f. Entwicklungsmech., v. H. 1; and Morphol. Jahrb., xxi (1897); S. PATON, Johns Hopkins Hosp. Rep., ix (1900); S. HATAI, J. of Compar. Neurol., xi (1901). (H.H.)

Spontaneity [Lat. *sponte*, voluntarily]: Ger. *Spontanität*; Fr. *spontanéité*; Ital. *spontaneità*. (1) A type of activity in which inner or immanent elements predominate.

Spontaneity is a conception relative to transeunt or mechanical causation, on the one side, and SELF-ACTIVITY (q. v.) on the other. The adjective spontaneous is applied to functions which are relatively independent of external stimulation or causation, as 'spontaneous sympathy,' and yet are not REFLECTIVE (q. v.). Cf. also ORGANIC (in psychology).

(2) In Kant: see RECEPTIVITY.

(3) Cf. Eisler, Wörterb. d. philos. Begriffe, 'Spontanität.' (J.M.B.)

Spontaneous: see SPONTANEITY, and ORGANIC (in psychology).

Spontaneous Generation: Ger. *Urzeugung*; Fr. *génération spontanée*; Ital. *generazione spontanea*. A BIOGENESIS (q. v.): the production of living beings, not springing from pre-existing living beings.

The occurrence of spontaneous generation under any known circumstances is now almost universally denied. The belief in it, founded chiefly on the appearance of moulds and putrefying organisms in apparently well-closed vessels, was once widespread, and even as late as 1870-80 had defenders among scientific men. It is now demonstrated that the experiments, upon which the belief was based, did not exclude sources of error, and

that when these sources of error have been excluded, no evidence in favour of abiogenesis can be obtained. Under the old form of experiments, germs were not shut off from entering; when the entry from outside is prevented, no life appears in any medium heretofore experimented with. (C.S.M.)

Spontaneous (or **Fortuitous**, or **Accidental**) **Variation**: see **VARIATION** (in biology).

Spore [Gr. *σπορά*, seed, offspring]: Ger. *Spore*, *Keim*, *Keimspore*; Fr. *spore*; Ital. *spora*. Small cells, usually produced in considerable numbers by fission of a single cell, each small cell to serve for development into a new individual.

Spores are of frequent occurrence among flowerless plants, but among animals are to be found only in a few Protozoa, e. g. *sporozoas*. Cf. **AGAMOGENESIS**. (C.S.M.)

Sport (in biology) [prob. abbrev. of *disport*]: the English term is in use in the other languages. A variation departing widely in any direction from the average, but still following the principles of heredity and classification.

The term is due to Francis Galton. Terms of similar connotation are *freak*, which applies to variations out of the range of classification with other variations, yet not abnormal from defect; **MONSTER** (q. v.), variation which is abnormal, or much malformed. A man seven feet tall is a sport; a man with eyes of different colours would be a freak; the Siamese twins were monsters. Further, a prodigy is a variation in the direction of the exaggeration of some one character or faculty, resulting in great excellence. (J.M.B.)

Spurious Proposition: foreign equivalents are not in use. (1) A proposition which from the constitution of the universe must be true (De Morgan, *Syllabus of Logic*, § 76).

(2) B. I. Gilman (*Johns Hopkins Univ. Circ.*, August, 1882) calls the conclusion from two particular premises *spurious in the first degree*. Thus,

Some *A* is *B*,
Some *C* is not *B*,
∴ Some *A* is not some *C*.

This asserts the existence of an *A* and of a *C*, and further, that the number of the aggregate of the *A*'s and *C*'s is at least two. The conclusion from two premises, of which one is particular and the other spurious in the first degree, gives a conclusion spurious in the second degree. There are also anti-

spurious propositions, which are the precise denials of spurious propositions of the same degree. (C.S.P.)

Square (of opposition): see **OPPOSITION** (in logic).

St. Augustine: see **AUGUSTINE**, **SAINT**, **AUGUSTINIANISM**, and **PATRISTIC PHILOSOPHY** (6, b).

St. Thomas (philosophy of) (1) and (2) **Roman Catholic Theology**.

I. *St. Thomas*. (1) The purpose of the philosophy of St. Thomas, called the 'Angelic Doctor,' and 'Angel of the Schools,' as indeed of all mediaeval endeavour, was to effect a conciliatory union between the truths of reason and the doctrines of Christian faith. This purpose, more or less explicit in Christian thinking from the days of the Alexandrian school of Origen and Clement, became a matter of prime necessity and interest in the complex thought-conditions of the 13th century, of which St. Thomas is so largely a product. The introduction of the complete works of Aristotle into Latin Europe, through the instrumentality of the Arabs, about the year 1200, and the direct Graeco-Latin versions of the Aristotelic writings subsequently made, with a view to discover what warrant there was for the extravagant interpretations put upon the Stagyrte by the Arabs, broadened the Latin mind considerably and placed Aristotle in the foreground as a source of knowledge. Upon one of these direct versions—that of William of Moerbeke, which appeared in 1263—St. Thomas based his commentary of Aristotle. Although in the nature of events Aristotle thus entered largely as an instrumental factor in the organic body of knowledge which St. Thomas reconstructed, the attitude of the latter towards the former, while sympathetic throughout with the method, and for the most part also with the views of the Stagyrte, was the attitude of a critic, not that of a slavish copyist, as an examination of the texts or a perusal of the list of Aristotelic errors abundantly discloses (Talamo, *L'Aristotelismo della Scolastica*, Pt. II. chap. ii-v. 151-206, 3rd ed., Siena, 1881). Plato and the Neo-Platonists, especially Dionysius Areopagita, were less extensively represented in the Thomistic synthesis, their representation being confined to a few points in theodicy and aesthetics. The Fathers, both Latin and Greek, notably St. Augustine, and the Arabs and Jews of the middle ages, notably Averroes and Maimonides, were drawn upon as philosophical sources while the Scriptures, together

with the writings of the same fathers and the conciliary teachings of the Church, furnished the theological matter for elaboration. Thus, on its material side, the philosophy of St. Thomas represents the absorption of the materials of ancient and contemporary culture into the body of a new scientific life.

(2) The rational side of the Thomistic synthesis was devoted to the problem of the dividing lines between philosophy and theology, which had to be determined with theoretical and practical precision. The distinctive dogmas of Christianity, such as the Trinity, Incarnation, and Sacraments, were carried over into the domain of purely revealed theology, the truth of which reason could not demonstrate scientifically, but only support by analogies and hypothetic arguments of fitness drawn from nature. The office of the theologian, therefore, is simply to show that reasons adduced against these higher dogmatic truths are either false or inconclusive. The immortality of the soul, the existence and attributes of God, were retained within the sphere of rational demonstration, which was akin with the *natural* theology of Aristotle. The criterion of philosophy was evidence, that of revealed theology was authority; which is accordingly the weakest source for reason, but the strongest one for faith. Philosophy and theology are distinct in object, principles, and mode of procedure (*Summa c. Gent.*, Lib. II. cap. 4), but yet related as complete parts each to the other.

The Latin Averroism of Siger of Brabant, who introduced the Arabic idea of the twofold nature of truth about 1266—namely, that a proposition demonstrably true for reason, such as the oneness of the intellect and the eternity of the world, might be equally false for faith—must be reckoned an indirect factor in the development of the rational side of the Thomistic synthesis. Against it St. Thomas urged the essential harmony of all truth, whether natural or revealed, conceiving the respective spheres of faith and reason, grace and nature, miracle and natural law, Church and state, as additions to, and complements of, each other, not contradictions. These respective spheres are but different stages in the realization of a single divine purpose. They but indicate the self-existent acting on a higher plane and working out one and the same eternal world-plan by means of a superior parallel order of phenomena. *Gratia non tollit, sed perficit naturam*. The supernatural does not destroy, it completes the natural. In carrying out

this idea, which is the soul of all his endeavour, he united the teleology of history developed by the Fathers with the teleology of nature developed by the Greeks, and thus completed, as Windelband says (*Hist. of Philos.*, Pt. II. chap. ii. 327, Eng. trans., 1895), 'the most deeply and widely reaching union of the ancient and Christian conceptions of the world that has ever been attempted.' The following paragraphs present some of the details interwoven in this synthetic scheme. (The best complete edition of his works is the Parma edition, 1852 ff. Werner, *Der heilige Thomas von Aquino*, 3 vols., Regensburg, 1859, is exhaustive. On Averroism, see Renan, *Averroès et l'Averroïsme*, Paris, 1862-5; also Mandonnet, *Siger de Brabant et l'Averroïsme latin au xiii^{me} siècle*, 1899. *Das Verhältniss des Th. v. Aquino zum Judenthum und zur jüdischen Litteratur*, by Guttman, is a study of Thomistic sources. C. Jourdain, *La philos. de St. Thomas d'Aquin*, Paris, 1858, gives an excellent account of the Thomistic philosophy, its source and method.)

(3) All knowledge starts with sensation: there are no innate ideas. The singular object is apprehended as such through sense; while the intellect, abstracting from all singularity, grasps it as a nature or essence. The result of this first abstraction is a direct universal.¹⁴ By comparison of several objects thus abstractly apprehended, the intellect detects the recurrence of a common element in all, and proceeds to rethink this common element according to the relation of universality disclosed to reflex thought. The result is a reflex universal, a *secunda intentio*, which as such is a pure creature of the mind, yet not without foundation in, and objective reference to, the individual objects from which it is drawn. The individual alone exists as a complete thing, and the real similarity of individual things is the ground of the universal. Considered with regard to God, who is essential thought-life, the universal is real with the reality of the divine ideas which are the causative prototypes of things. He thus placed the solution of the universals on an empirical basis, although adopting the threefold existence of the universal excogitated by Averroes (*De Universal.*, opusc. 50, tom. 28, Parma ed., 1875; *Summa contra Gent.*, Lib. I. cap. 65; Talamo, op. cit., 393, 398; Janet et Séailles, *Hist. de la Philos.*, 510-2).

(4) Metaphysics is the science of real being as such. Being is either real or mental, according as it signifies one of the ten cate-

gories, or the mere truth of a proposition (negations, privations, &c., which have no essence). Real being is composed of essence (what is contained in the definition, i. e. specific constituents, or real capacity to exist) and existence (act of essence, fulfilment of the capacity to exist). Essence and existence (*esse*) bear to each other the relation of capacity (*potentia*) to fulfilment (*actus*), and are thus really, though inadequately, distinct. Existence (*esse*, *existentia*), which also signifies the copula of a proposition (*ens rationis*) and an essence (*ens possibile*), is in its real acceptance the act of essence, viz. *that by which* a thing is posited outside its causes in the field of nature. Being (*ens*, the complete subject which is) is resolvable therefore into the two incomplete concepts of essence and existence. And hence real being may be described as 'that which has (*ens actuale*), or may have (*ens possibile*), existence.'

The transcendental notions (one, true, good) are only the relations of undividedness (*unum*), desirability (*bonum*), and conformity with some intelligence (*verum*) added to being. Transcendental truth is the very entity of a thing, viewed primarily as in actual conformity with its prototype in the divine creative mind, and secondarily as capable of effecting a conformity between the human mind and itself.

As the notion of being is the product of the highest analytic abstraction, it represents objectively a minimum content and a maximum extent. It is an indeterminate concept expressive of all things *implicitly* and of nothing *explicitly*, neither God nor thing, neither substance nor accident. To being as such no real object corresponded, since nothing can merely be, without being determinate, qualified, individual. Being, therefore, does not signify an objective content either wholly the same (*univocum*) in all of which it is predicated, or wholly divergent (*aequivocum*); neither does it point to universal identity (*identicum*); it merely expresses the proportional agreement (*analogum*) of all things, including God, in the fact that all really are *subjects existing*, howsoever divergent, even infinitely, such subjects may chance to be. The objective content of being is invariable in expressing this fact: it varies in each case in accord with the nature of the subject that is said to be. To view being therefore as the concept of the infinite, is to confound the abstract order with the concrete, as the Neo-Platonists did, or to fall into the error of Pantheism. This theory of being, supple-

mented by the Aristotelic division of causes and the idea of 'matter and form,' was his point of leverage against Pantheism and the constructive basis for his conception of God (St. Thomas, *Opusc. de ente et essentia*, cap. 1, 6; *Metaphys.*, Lib. IV. lect. 1; *Contra Gent.*, Lib. I. cap. 31-4; *Summa Theol.*, Pt. I. quaest. 13, art. 5, 6; *Quaest. Disp. de Potentia*, quaest. 7, art. 7; *Quodlibet*, 9, art. 3. Cf. also Prisco, 'La Metafisica di San Tommaso,' in *L'Accademia Romana*, iii. 451-75, 1883; iv. 191-245, 1884).

(5) Cognition was explained as the representative presence (*species intentionalis*) of the thing known within the knower. This theory of the 'species' was not that of an efflux from objects, as Hauréau wrongly states and as St. Thomas himself distinctly repudiates (*Quaest. Disp. de Verit.*, quaest. 2, art. 5, ad. 15). The 'species' was the result of the action of the object (*species sensibilis impressa*) and the reaction of the subject (*species sensibilis expressa*); and the conscious state aroused by this representation of the object was called a 'species intentionalis,' to show that there was a genuine relation of similarity between the mental reproductions and the extra-mental objects, although both differed *toto coelo* in nature. The 'species' was therefore no fictitious entity midway between subject knowing and object known.

The keynote to Thomistic metaphysical psychology is the essential distinction between a lower or sensuous, and a higher or rational, grade of consciousness. The essential irreducibility of attention, abstraction, comparison, reasoning, self-consciousness, and free will to organic processes, such as those of the external senses, the imagination and the sensuous memory, is the ground of spirituality and immortality. The latter phenomena are accounted for by admitting the co-operation of the soul or vital principle with the organic co-factor; the former demand intrinsic independence of the organism for their display, and hence point to an inorganic principle as their exclusive subject. Thought is not a passive transformation of sensations; an inner attentive energy of the mind (*intellectus agens*) disengages at first the essentials of the sensuous presentation (*abstrahit essentiam*), and then the mind itself (*intellectus passivus*), out of this prepared datum, proceeds to generate the pure forms of thought (*exprimere intelligendo*). This was an application of the Aristotelic theory of the 'active and passive intellect' to the problem of the bridge between

sensation and conception. The intellect is acknowledged to be objectively dependent on sense for the acquisition of the materials of its knowledge: it is subjectively independent of the organism, however, in the display of its irreducible activities of thought and volition. This intrinsic independence of the organism which the soul shows (even while united with the body and conditioned by the health or disease of the imagination and memory) by the very fact of its being the exclusive subject of its own higher functions, is the proof of spirituality and the pledge of immortality. This view of St. Thomas does not imply an 'anima separata,' but an 'anima separabilis.' There is only one *specific* substance in man—the compound self or ego. The soul was not a mere thinking machine, but the life-giving principle of the body as well, discharging the several functions of thought, feeling, and volition, either by itself or conjointly with the organism, as above stated (St. Thomas, *Summa Theol.*, Pt. I. quaest. 75–90, especially 79; *Quaest. Disp. de Anima*, I. art. 1, 2, 4, 10; *De Anima*, Lib. III. lect. 7; *Opusc. de natura verbi intellectus*. Cf. also Werner, *Der heilige Thomas von Aquino*, ii. 432–58, Regensburg, 1859; Liberatore, *Die Erkenntnislehre des heiligen Thomas von Aquino*, übersetzt von E. Franz, Mainz, 1861).

(6) The idea of God is not innate, but the result of demonstration, the proofs being reduced to five in the second question of the *Summa* (art. 2). The burden of these proofs is to show that the idea of God is to be framed by the elimination of all capacity for development (*potentialitas*), which is the essential feature of created reality, and by the conception of a pure actuality, essentially undevelopable, possessing all perfection, and subject to none of the existential, spatial, temporal, or causal limitations proper to the finite. The methods which he employs are two: analogy and negation. On the principle of analogy, i.e. the proportional similarity between the *being* of creatures and the *being* of God (see above, 4), the perfections discovered in things are affirmed of God, the prime source of all reality. The method of negation acts as a corrective. As God is self-existent Being (*ens per essentiam*) and creatures derivative being (*ens ab alio*), the imperfections of the latter, both as to substance and mode, must be denied of God, whatever perfection is affirmed being affirmed in an eminent way. Thus inquiry into things gives us the idea that they are causally derived, and further

inquiry into the nature of this causality abuts on the idea of an uncaused first cause. The nature of this first cause is set forth by means of the comparative analysis, just indicated, of essential and derivative being. God is simple, infinite, omnipresent, immutable, eternal, one: he is infinite knowledge, power, and will, creator, upholder, and provider, the efficient source of all being and the final destiny of man. Creation is the production of a thing in its entirety out of no pre-existent material by the sole power of the Self-existent acting according to a plan. The *possibility* of an eternal creation is an open question: the *fact* of the world's creation in time a matter of faith. God is *in* the world, though not *of* it, creating each human soul according as conditions demand, and working in all men and things as the purposeful and efficient universal cause. In this wise the Aristotelic, Platonic, Neo-Platonic, Patristic, and scriptural elements were interwoven in his synthetic conception of the Deity (St. Thomas, *Summa Theol.*, Pt. I. quaest. 1–26; *Contra Gent.*, Lib. I, II. On question of eternal creation see *Opusc. de aeternitate mundi contra murmurantes*; also, in Lib. II, *Sentent.*, dist. 1, quaest. 1, art. 5; *Summa Theol.*, Pt. I. quaest. 46, art. 1, 2; Talamo, *op. cit.*, 151–60).

(7) The ethical view of St. Thomas, grounded on the idea of God as the final destiny of man and the true end of deliberative human conduct, is nought else than the morals of mankind in history chastened and systematized in the light of Christian principles. His synthesis avoids the extremes of idealism and utilitarianism, and is accompanied by minute analyses of the passions, the proposal of counter virtues, and the detailing of the duties of bishops, citizens, rulers, and individuals. With him, ethics is the science of the means which lead to the end of human conduct. Moral welfare is not measured by any temporal good, but by the final possession of the essential good, God. The objective spring of action is disinterested love of the good and hatred of evil; the subjective springs are hope of reward and fear of punishment. The moral goodness of human action is determined by the conformity of the latter with right reason; conscience being the expression and application of this conformity. This proximate subjective criterion of morality is referred to an objective ultimate criterion, viz. the divine reason, or eternal law, which is the real ground of all morality and the source of all

law, natural and positive. Morality, with St. Thomas, was not the result merely of a commanding will, as with Scotus; it consisted in the intrinsic relations which the objects of man's choice bear to the all-ordaining intelligence of God. The human will is therefore to some extent determined by the intellect, and freedom of choice is limited to various possibilities as means to an end, but does not extend to the end in itself, which is the good. The primary precept of the natural law is that good should be done and evil avoided.

The state is rooted in man's nature. Social authority exists by natural right, and is to be employed for the common weal. The state is not an end in itself, but only a means to procure the temporal welfare of its citizens. The best form of government, theoretically, is the monarchical, tempered by an aristocracy and a democratic electorate (*Summa Theol.*, Pt. I. quaest. 105, art. 1). The Church has as its end the eternal destiny of the individual, and is therefore independent of, and superior to, the state, while both are but preparatory schools for the heavenly society of the blessed (*Summa Theol.*, 1^a, 2^ae, quaest. 91, art. 1; 93, art. 1, 2; 94, art. 2, 4; 105, art. 1; *De regimine principum*, Lib. I. cap. 15; Talamo, op. cit., 433-57; Contzen, *Zur Würdigung des Mittelalters*, &c., 24, Cassel, 1870; Baumann, *Die Staatslehre des heiligen Thomas*, &c., 7, Leipzig, 1873).

II. *Relation of the philosophy of St. Thomas to Catholic theology.* The vital principles of the Thomistic philosophy are still fundamental to Roman Catholic theology, such as the objectivity of thought, the essential distinction between sense and intellect, with its double consequence of a substantial spiritual principle or soul in man, and the immediate creation of each individual soul by the Omnipresent Infinite; the analogousness of being as opposed to Pantheistic identity; matter and form, at least as an ultimate metaphysical theory; the conception of God the Creator as *in* the world, though not *of* it, and the dependence of ethics on dogma. The synthetic view of St. Thomas, based upon the essential harmony and unity of the world-ground or God, and representing the supernatural order (faith, grace, Church, miracle) together with the natural (reason, nature, state, cosmic law) as a twofold realization of a single divine purpose, to be completed in the after-life for the spiritually fittest, is ever the ideal of Catholic theology. The Thomistic conception of the respective provinces and relations of

philosophy and theology (see 2, above), as well as the Thomistic order of presenting the revealed truths, remain as a framework, although filled in more substantially. The encyclical *Aeterni Patris* on the restoration of Thomistic studies, while commending the analytico-synthetic spirit (*sapientia*) of St. Thomas, discountenances a return to subtle or unsubstantial scholastic views, and suggests the incorporation of the results of modern research into the Thomistic synthesis (*Encyc.*, paragraph 4 from end). For the Catholic who, through the Church, accepts the Scriptures as the inspired Word of God, the essential subordination of the finite to the infinite reason is a rational consequence following on the admission of the historical fact of revelation. In framing his scientific conception of the world, such a one must needs make room for supernature in his universal scheme, and look upon reason and the panorama of the visible as only a part, not the whole, of the divine economy. Of such a world-view, St. Thomas Aquinas is the type *par excellence*, and he has left a good transcript of himself as such in the *Summa Theologiae* (Pt. I. quaest. 1, art. 8, ad. 2). 'Thomism,' therefore, is not St. Thomas stereotyped in minutest detail: it is the acceptance of a definite world-view with the principles and methods that give it articulate and rejuvenescent expression. Thomism, however, must be dissociated from the respective theories of determinism and indifferentism which have mutually claimed the patronage of St. Thomas in the course of the Bannezian and Molinistic controversies on grace and predestination. Critical reconstruction (Pecci, *Accademia Romana di San Tommaso*, v. 99-145, 1885) has abundantly disestablished both these views attributed, without objective warrant, to the Angel of the Schools (Lesserteur, *Saint Thomas et le Thomisme*, Paris, 1883; Jourdain, op. cit., ii. 237 ff.). (E.T.S.)

Literature: see citations in the various sections above, also under SCHOLASTICISM, and PATRISTIC PHILOSOPHY.

Stability (economic) [Lat. *stabilitas*, firmness]; Ger. *Stabilität*; Fr. *stabilité*; Ital. *stabilità*. (1) A condition of economic equilibrium, such that any disturbance produces a reaction that tends to bring matters back to the old adjustment. Cf. SUPPLY AND DEMAND, and UNSTABLE EQUILIBRIUM.

(2) A continued absence of marked economic change, to whatever cause it may be due.

(3) A set of social conditions favourable to

survival in the competition between different institutions.

The first use is the distinctively modern one, but all are equally accredited in scientific as well as in popular usage. (A.T.H.)

Stage (in mental evolution): see GRADE, and cf. SUBCONSCIOUS.

Stammering [AS. *stamur*]: Ger. *Stammeln*; Fr. *bégaiement*; Ital. *balbuzie*. An impediment of speech-utterance which causes the speaker to hesitate, stop, drawl, or rapidly repeat a sound, usually an explosive consonant, at which the stoppage occurred; thus inclusive of STUTTERING (q.v.).

It includes, in a wider sense, difficulties in pronouncing certain letters, hesitating or stumbling utterance, the transposition of letters or syllables, utterance of meaningless interjections, &c., all of which interrupt the flow of speech.

Stammering (with stuttering in the special sense) generally appears in childhood (four or five to thirteen or fifteen years), and often undergoes a spontaneous improvement with advancing age. It is apt to occur in children of weak, nervous temperament. It varies in degree from a slight repetition of sounds to an intense paroxysm not only of the vocal mechanism, but of the entire body. It occurs much more frequently in men than in women. It is markedly subject to emotional influences. Worry, excitement, ill health aggravate it; while careful preparation, as in public utterance or the abandonment of alcoholic stimulation, may remove it. It is a notable fact that stuttering disappears in singing. The defect is a functional interference with the complicated mechanism of articulation, and consists particularly in a faulty co-ordination between the voice-producing and the sound-forming factors of utterance. See the references noted under STUTTERING. (J.J.)

Standard: see NORM.

Standard Stimulus: see NORMAL STIMULUS.

State (and **Condition**) [Lat. *status*, from *stare*, to stand]: Ger. *Zustand*, *Verhältniss*; Fr. *état*, *condition*; Ital. *stato*, *condizione*. Terms used loosely for quality, property, aspect, relationship, &c. Any descriptive predicate may indicate a thing's state or condition, e.g. from STATE OF CONSCIOUSNESS (q.v.) to STATE OF NATURE (q.v.). (J.M.B.)

State is a term used in such very different senses by different writers that it can hardly be said to have a generally acknowledged

meaning. Some understand it properly to apply to an unalterable determination or property; but the majority, in accordance with its original meaning—a posture in standing—take it rather to imply, on the contrary, a temporary condition, although no doubt in some cases it refers to an enduring condition. It is usually understood to imply passivity, yet in some expressions its implication is the reverse. (C.S.P.)

State or Community (political): Ger. *Staat*, *Bürgerschaft*; Fr. *état*; Ital. *Stato*. A society, the members of which render habitual obedience to an authority within that society which does not render habitual obedience to any external authority.

Every permanent association must possess some organ of government to which its members render habitual obedience, at least, in matters coming within the scope of the association. Without such an organ of government the association would be impotent. This organ of government, again, must have a certain sphere of action within which it is free, otherwise it would be useless. Thus the existence of the family implies obedience of the children to the parents and a certain discretion left to the parents by society. What distinguishes a political community from other forms of association seems to be this, that the obedience which the ruler claims is indefinite in extent, and that the independence of the ruler is similarly indefinite. Thus a shareholder in a company is only bound to submit to the resolutions of the company in matters affecting his shares in its stock. The resolutions of the company are binding only in those matters with regard to which they have been authorized by law. It is true that the distinction is only one of degree. In some religious associations, e.g. the Catholic Church in the middle ages, the sphere of authority claimed by the ruling power has been at least as wide as that pertaining to the sovereign of a political community. The ruling power was at least as independent in the exercise of authority as any contemporary sovereign. In fact, an Englishman or Frenchman of the 12th century might be said to be a member of two distinct political communities—his native kingdom and the Catholic Church. Trading associations, again, have sometimes acquired powers which were strictly political, and have become *imperia in imperio*. On the other hand, political communities have differed very widely both as regards the scope of the ruler's authority and the degree of the ruler's inde-

pendence. The scope of the ruler's authority was one thing in a Greek city, another in a mediaeval kingdom, another in a centralized modern state. Similarly, the independence of the ruler varies indefinitely with circumstances. It is one thing in a fully sovereign state, another in a state which acknowledges a suzerain, another in a state which is a member of a federation, and so forth. But, on the whole, the political community is distinguished from other associations chiefly by (1) the indefinite extent of the obedience which the governing power may claim; (2) the indefinite extent of the independence which the governing power may enjoy.

Theory of the State*. See also under STATE (philosophy of).

(F.C.M.)

State (philosophy of): Ger. *Staatswissenschaft*, *Rechtslehre*, *Rechtsphilosophie* (see below); Fr. *philosophie sociale (de l'état, du droit, de l'histoire)*; Ital. *filosofia del diritto* (or *politica*). The philosophy of the state treats of the life of man so far as it is a life in community.

(B.B.-J.M.B.)

The *Republic* of Plato and the *Ethics* and *Politics* of Aristotle are the earliest examples. To this study, which he conceived as an inquiry into the good for man with a view to practice, Aristotle gave the name of 'politic' (πολιτική), a substantive in adjectival form analogous to those from which we derive such terms as music and dialectic, and capable of being understood as the name either of an art (τέχνη), or of a science (ἐπιστήμη), or of any kind of methodic study or pursuit (πραγμάτεια or μέθοδος). The meaning of the name 'politic' as the study of the good for man must not be narrowed by the contrast implied in the names of those of Aristotle's writings which are known as the *Nicomachean Ethics* and the *Politics*. 'Politic' is the object-matter of the *Ethics* no less than of the *Politics*, while the word ethic (ἠθική), like the word logic, is not to be found in Aristotle as a substantive, i.e. as the name of a distinct study (Burnet, *The Ethics of Aristotle*, xxvii).

In other words, Aristotle, like Plato, regarded the good for man as, in its nature, capable of realization only in a community of souls or selves, and did not think of

separating the study of the good of the individual from the study of the good of the community. The *Ethics* and *Politics* treat respectively of the nature of this good and of the means of realizing it by legislation, but it is the same good, that of the social creature man, with which both treatises are dealing. The name 'politic,' due to the Greek πόλις or city being accepted as the ideal and therefore typical human society, may be objected to, it appears to Aristotle, because it does not sharply bring out the sameness of individual and social good. He does not suppose that it could be objected to for assuming such a sameness (Burnet, op. cit., *Introd.*, § 14). Aristotle's 'politic' must have been rendered 'moral philosophy' in the source from which Shakespeare drew in *Troilus and Cressida*—'Not much Unlike young men, whom Aristotle thought Unfit to hear moral philosophy' (διὸ τῆς πολιτικῆς οὐκ ἔστιν οἰκείος ἀκροατῆς ὁ νέος, *Eth. Nic.*, iii. 4, 5).

Turning to modern thought, it is natural to reserve the title 'philosophy of the state' for those forms of theory, whatever name they may adopt, which approach the phenomena of social life from the 'philosophical' point of view. We may say, perhaps, that philosophy is an attempt to see things in their relation to completeness or perfection; and the philosophical point of view, in considering the phenomena of the state, would then appear, in accordance with the example of Plato and Aristotle, to be concerned with the relation of the state, as a community of souls or selves, to the completeness or perfection of life. Owing to historical causes, much speculation that is substantially of this type has appeared in connection with the idea of social contract or of natural right. The political philosophy of Hobbes, Spinoza, Locke, and Rousseau might be ranked under the heading of *Rechtslehre* (theory of right) or *Naturrecht* (natural right), which is explicitly adopted by Kant and Fichte, and a multitude of minor writers, in Germany. The full title of Hegel's great work on the subject runs—*Grundlinien der Philosophie des Rechts, oder Naturrecht und Staatswissenschaft im Grundrisse* (Outlines of the Philosophy of Right, or Natural Right and the Science of the State in Outline). The German 'theory' or 'philosophy of right' corresponds to what an English thinker might describe as the theory or philosophy of law. But the former has a wider meaning, suggesting a science in which all forms of recognition of what ought to be, within a human society,

are brought into connection, and consideration is not restricted to the phenomena of positive law. It implies, therefore, a wider treatment than that of which Austin's *Jurisprudence* is an example. When J. S. Mill's *System of Political Economy* professes on its title-page to include 'applications to social philosophy,' we are probably to understand that it does not leave out of account the bearing of economic facts upon the completeness of human life. There are, however, two distinctions between Aristotle's 'politic' and the modern philosophy of the state.

(1) The practical aim which Aristotle claimed for his 'politic' is usually repudiated by modern political philosophy. Not that it holds theory to be idle or devoid of reaction upon human conduct, but that it conceives of philosophy mainly as an attempt to *understand* the forms of life; and these, before they can be completely understood, must be themselves fairly complete, and no longer 'in the making.' Aristotle's own relation to the Greek city might even be cited as a striking confirmation of this modern point of view.

(2) In face of the literature of ethical science in modern times it would be a paradox to maintain that the philosophy of the state, like Aristotle's 'politic,' is identical with, or even includes the science of ethics or moral philosophy. Nevertheless, its tendency to do so is plainly traceable, for example, in Hegel, who has no specific treatment of ethics outside the philosophy of the state. And the emphatically isolated treatment of moral philosophy, as inherited by the modern world from the Stoics, and pursued by the English schools and by Kant, will be found as a rule to indicate a fundamental difference of philosophical principles as against that phase of idealism which has laid most stress on the philosophy of the state.

A modern form of thought (though anticipated by Books VIII and IX of Plato's *Republic*), which is, in fact, an application of the philosophy of the state as here understood, is the philosophy of history (*Philosophie der Geschichte*). It endeavours to see, in the succession of social forms in time, that relation to completeness of life which the philosophy of the state attempts to analyse in its general principles and in typical examples. Kant has thus summarized its conception in a single sentence: 'We may regard the history of the human race on the large scale as the accomplishment of a latent plan of nature, to bring to pass a political constitution which

is inwardly, and to this end also outwardly, perfect, as being the only condition in which she can fully develop all the capabilities which she has implanted in humanity' (Kant, *Werke*, vii. 329, Rosenkranz, *Idee zu einer allgemeinen Geschichte in weltbürgerlicher Absicht*, which is included under the general heading *Zur Philosophie der Geschichte*). It therefore aims at a combination of the rational and historical, which, as Kant says (*ibid.*, 332), sounds more likely to produce a fiction than a history (Aristotle, we remember, has said that poetry is more philosophical than history). Thus Schelling at one time held that a philosophy of history was a contradiction in terms (*Werke*, i. 466). If, however, the possibility of a philosophy of the state is admitted, the possibility of a philosophy of history can hardly be denied.

The philosophy of the state has further to define its position in regard to (1) its difference from, and (2) its affinity with, modern SOCIOLOGY (q. v.). This name is due to Comte, and is employed to-day by writers in all the great European languages. For Comte it was equivalent to social physics, a significant term; and the more general expression social science (*science sociale*), originated, it would seem, by the French economists of the later 18th century, is widely used to much the same effect (J. D. Rogers, in *Dict. of Polit. Econ.*, 'Social Science,' who points out that, as in Vico's *Scienza Nuova* and Comte's *Sociologie*, the conception of a science of society has repeatedly been claimed as a new departure in modern Europe). (1) Its difference from the philosophy of the state consists in this, that sociology has been faithful to the 'positive' point of view from which Comte initiated it. It has been conceived as a distinctively modern science, on the analogy of the natural sciences, and greatly influenced by biological analogies and considerations, especially, of course, by the ideas which pass under the name of Darwinism. Sociology, then, in its inception and intention, is a natural science. 'It is an interpretation of human society in terms of natural causation, . . . (it) is an attempt to account for the origin, growth, structure, and activities of society by the operation of physical, vital, and psychical causes, working together in a process of evolution' (Giddings, *Princ. of Sociol.*, 1896, 7, 8).

So far, sociology seems to begin at the other end from the philosophy of the state. The philosophy of the state is 'critical' through-

out, in the sense in which philosophy makes use of that term. Its leading idea is the estimate of degrees of completeness, degrees of self-expression, degrees of harmonious life. Historical and economic explanations, laws and causes of progress and decadence, are not as such its primary problems. It asks about the state what other forms of philosophy would ask about science or fine art or religion, viz. how far are they respectively examples of a perfect or harmonious experience, and if not themselves examples of it, how far they throw light on what such an experience would be? Nevertheless, it is plainly impossible to judge of the completeness of any form of life without understanding what it is and how it works; and therefore there is probably no province or result of sociological research which does not aid in vitalizing and enriching the philosophy of the state.

And (2) in recent years a closer affinity between the two has revealed itself. Even when sociology was mainly guided by biological analogies, a curious double tendency was noticeable in their bearing (see H. Spencer, *Sociology*, i. 586). If the theory of the struggle for life between individuals pointed to an atomism in a flat contradiction with philosophical conceptions of the state, yet, on the other hand, the analogy of an individual living body, which had attracted the attention of ancient thinkers, was still influential in pointing to a unity which should be more than mechanical. And when, by the mere force of facts, sociology repudiated its founder Comte's rejection of psychology, and was compelled to postulate some kind of mental unity as the focus of social phenomena, the difference which held it apart from the philosophy of the state bade fair to be done away. When we find the sociologist basing his science on such conceptions as the mind of a crowd (Le Bon), 'imitation' and 'social logic' (Tarde), or 'the consciousness of kind' (Giddings), we are inclined to conclude that no difference remains between sociology and the philosophy of the state. The mind or the self (Baldwin) has become for both alike the centre in which alone the facts of social life can attain to full intelligibility. (Notably this point has been brought out by M. Tarde with reference to social statistics, *Les Lois de l'Imitation*, 115.)

In becoming a science of mind, then, sociology seems to have blended with the philosophy of the state. But yet a difference remains. Sociology has still before it the ideal, not indeed of a physical, but of a natural science;

and it joins hands with psychology in the sense in which psychology shares this ideal—as an impartial science, whose watchwords are law, process, and genesis, and which is indifferent to the distinction between higher and lower forms of life (see Stout, *Analytic Psychol.*, Introd.).

The modern philosophy of the state, as we found it, for example, in Hegel's *Philosophy of Right*, may best be understood by regarding it as the theory of Plato's *Republic* expanded and differentiated in accordance with the deeper individuation and fuller integration of a modern community.

Plato's state, as outlined in the *Republic*, presents to a modern eye the appearance of what he calls, in another sense, a 'minimum community' (*ἀναγκαιωτάτη πόλις*)—a community reduced to bare essentials. For this there are many reasons, which cannot be entered upon here. But, whatever Plato's intention may have been, for us his work serves the purpose of a diagrammatic representation of a state. A true community, he seems to tell us, must be above all things a single spiritual system, and further, a single system presenting three aspects at the least, viz. intelligence to guide itself, resolution to defend itself, and the desires and capacities which underlie all bodily living, to maintain itself. Pressing home the inquiry into these indispensable attributes, he shows us that in every soul or self there is some spark of all of them, but that in the community as a working system they are represented by great organs or institutions, the 'classes,' as he calls them, in which the several souls combine according to the predominant gifts of each—the statesman, the knight, and the trader or man of industry—to render their specific service to the whole. And as all action springs from the mind, while the mind becomes a definite system only in action, it follows that every soul or self in the community is a microcosm of which the state or community is the macrocosm, or that the whole visible community is the body of which a whole connected system of spiritual qualities is the soul. Thus the organization and harmony of the state at once expresses, and guarantees by expressing, the organization and harmony of the soul, for unfulfilled or undisciplined capacities in the latter imply waste and friction in the former. And, therefore, the order of the state may be portrayed as a system of moral excellences, wisdom, courage, temperance, and justice, which must all (if we press the matter home)

be in some degree present in the inmost structure of every self, as a unity of reason, spiritedness, and desire; but each of which will be more especially the predominant characteristic of a certain class or organ of the commonwealth—wisdom of the statesman, disciplined courage of the knights, temperance as a right relation between rulers and ruled, and, we must suppose, as an attribute of the traders and the workmen, being a right activity with regard to bodily necessities. And the unity and harmony of the whole community, and that inner unity and harmony of the individual mind which is at once its reality and its reflection, may be doubly described as justice, or an autonomous discharge of duty by every member, and as love, or the sentiment of a natural kinship; the feeling, as it were, of a single enormous family.

In this diagrammatic representation, simplified to the very minimum conceivable as a society, or perhaps beyond it, we miss nearly all of the elements which form the interest and difficulty of a modern state. The vast complex of institutions and corporations which now seem to stand between the individual and the state, each in itself a whole world of feeling and tradition, such as the churches, the universities, the great organized professions, and the machinery of representative government, and, again, the family and the world of private enterprise and commerce and industry, Plato in part had never met with, and in part had struck out of his diagram.

Hegel has boldly included the family and the world of economic competition as natural and necessary institutions, resting on natural and necessary aspects of mind, within the great totality or ruling idea of the state. The differentiation is immeasurably more subtle, and the opening for self-contradiction within the system is wider, than Plato's diagram admitted; but the principle is the same as that according to which, for example, Plato found the true characteristic development of individual spiritedness in the courage which is the knightly temper of a disciplined patriot soldiery. Just so, the natural affections, for Hegel, find their proper outlet in the family, and at the same time are tamed within it into certain necessary phases of the true citizen temper, and spread a spirit of kinship throughout the entire community.

And in the same way the 'bourgeois society' (*bürgerliche Gesellschaft*), which is his name for the community when regarded from the

point of view of the classical political economy, stands for a necessary aspect of the complex modern spirit, the aspect in which the particular self takes shape under the severe discipline of the competitive world, operating through its private interests, and not by external despotism, as a unique service-rendering individual member of the universal social mind. Thus the complexity and expansion of modern institutions involves a correlative complexity and intension of the individual consciousness, which for the modern theorist, as for Plato, is a focus or mirror of the whole as it were from a particular angle and in a particular perspective. Every institution or social organ may thus be regarded as an ethical idea, and the state, or the working adjustment and supreme criticism of them all, as the system or totality implied, however inadequately realized, in the relative unity of every individual consciousness. The philosophy of the state is for Hegel a chapter in the philosophy of mind.

This is the key to the meaning of such phrases as the social self, or the real or general will, made current by Rousseau and his descendants on the German side. It is in the development and organization of capacities which come through the social order that the particular human being finds a clue to the way in which he can make the most of himself. The mind present in society, in its relation with a given undeveloped self, may be compared to a far-reaching theory in its relation with an isolated sense-perception about the same subject-matter. The self finds its real meaning in the social mind, as the sense-perception finds its real meaning in the completed theory. In both cases the absorption involves a transformation. That which we now really aim at, and are demanding to become, is something which we should not recognize if we now saw it in a completed form. Just so, to use a hackneyed illustration, the sense-perception that this apple falls to the ground is not recognized by the untrained mind when transformed into the Newtonian theory of gravitation. The social self, then, or real or general will, is that which, if we completely had it, would be a satisfactory development of our nature. Any approach to it, therefore, such as the relative expansion and organization which an actual society secures for our self, is so far a categorical imperative as against our half-developed personality.

Here, then, is the inherent principle and

limit of state coercion. In essence, such coercion is the reaction of the awakened on the unawakened self through the only means which are palpable to the latter. Its limit arises necessarily from the fact that the direct appeal to the unawakened self, or the self which falls asleep in a routine—an appeal not only through the menace of force, but through very various forms of custom, tradition, and the influence of prestige—may readily have the effect of throwing into the sphere of automatic habit or mere submissiveness concerns which demand the best energies of the awakened mind. The aim, therefore, is plainly to effect the right demarcation between the sphere of the fully awakened and that of the drowsy or routine-loving, or even incompetent and potentially rebellious, self.

The sphere of the latter will always be by far the larger in magnitude; for routine is the very machinery of existence. The work of social skill is to shape the submissive automatic life so that it may sustain, without encroaching upon, the energies of the fully awakened and progressive intelligence and affections.

It should be borne in mind that all first-rate work in archaeology, the theory of religion, political economy, and other definite branches of social research (e.g. the history and theory of charity), not to mention that mixture of narrative and judgment which is called 'history' *par excellence*, treats in a profound sense of human life in communities, and very often with a far more direct insight and more thorough and successful grasp than abstract social theory, which is plagued with general analogies and attention to prehistoric problems. A people, ancient or modern, should be studied as a whole like a living creature, from its food and habitat up to its instincts and ideas, as, for example, ancient Greece has been studied. From this point of view the methods of Le Play have typical importance.

Literature: an important source of the philosophy of the state must always be the Republic of PLATO, and the Nicomachean Ethics, with the Politics, of ARISTOTLE. The earlier modern history of the subject is closely bound up with the theory of the Law of Nature, Natural Right, and the Social Contract as treated by SPINOZA, HOBBS, LOCKE, and ROUSSEAU; for the reason and nature of this connection see MAINE, *Ancient Law*; RITCHIE, *Natural Rights*; and T. H. GREEN, *Princ. of Polit. Obligation*. From Rousseau the tradition passes, gathering up elements

drawn from VICO and MONTESQUIEU'S conception of the spirit of a people, to HERDER, KANT, and their successors; see LEVY-BRÜHL, *De l'Influence de J.-J. Rousseau en Allemagne*, Ann. de l'École libre des Sciences Politiques, Juillet, 1897. For Kant's views, see his Werke (Rosenkranz), vii. 315, *Zur Philos. d. Gesch.*, including a criticism of Herder's ideas, and ix. 1, *Rechtslehre*. FICHTE'S main writings on the subject are Werke, iii. 1, *Grundlage des Naturrechts* (1796, earlier than Kant's *Rechtslehre*), and *ibid.* 389, *Der geschlossene Handelsstaat* (1800), perhaps the first document of definite Socialism in Germany, and *Nachgelassene Werke*, ii. 495, *Syst. d. Rechtslehre* (delivered as lectures at Berlin in 1812). For SCHELLING, see his *Neue Deduction d. Naturrechts*, Werke, Abth. 1, i. 245, and *Abhandl. ü. d. Frage ob eine Philos. d. Gesch. möglich sei*, *ibid.* 461. HEGEL'S *Rechtsphilosophie* (published 1820) and *Philos. d. Gesch.*, delivered as lectures, 1822 and later, should be compared with *Philos. des Geistes* (part of the *Encyclopedia*), published 1817 (trans. Wallace, 1894, with Introduction), where a sketch of the Philosophy of Right appears as the chapter on 'Objective Mind.' Note also HEGEL'S *Krit. d. deutschen Verfassung und Syst. d. Sittlichkeit*, written 1802 (see Wallace, *op. cit.*, clxxx). In recent literature have appeared T. H. GREEN, *Princ. of Polit. Obligation*; RITCHIE, *Nat. Rights*; MACKENZIE, *Introd. to Social Philos.*; BOSANQUET, *Philos. of the State*; NEWMAN, *Politics of Aristotle*, i. *Introd.* Note also WALLACE, *Introduction to his translation of Hegel's Philosophy of Mind* (see above), and the same author's posthumous *Lectures and Essays on Nat. Theol. and Ethics*, containing important studies of Rousseau ('Our Natural Rights'), Fichte, Hegel, and Nietzsche.

Between sociology and the philosophy of the state lies the study of politics in the modern sense; the phenomena of communities under government considered with reference to the way in which they are governed—a positive study, which its subject-matter makes essentially teleological. Of such a nature are FREEMAN, *Compar. Politics*; SEELEY, *Introd. to Politics*; MILL, *Representative Government*; BAGEHOT, *Physics and Politics*; SIDGWICK, *Elements of Politics*. See also the citations given under SOCIOLOGY, and SOCIAL PSYCHOLOGY. (B.B.)

State of Consciousness (or **Conscious State**): Ger. *Bewusstseinszustand*; Fr. *état de conscience*; Ital. *stato di coscienza*. CON-

SCIOUSNESS (q. v.) 'now' or 'at present,' with all that is in it.

So when we speak of past states of consciousness, we mean consciousness as it was 'then,' i. e. in an earlier 'now'; and a future state of consciousness is consciousness 'then,' i. e. a future 'now.'

(J.M.B., G.F.S.)

State of Nature: Ger. *Naturzustand*; Fr. *état de nature*; Ital. *stato di natura*.

(1) That moral and social condition in which mankind would be in the absence of political organization, civil law, and government. 'A state of perfect freedom to order their actions and dispose of their possessions and persons as they think fit, within the bounds of the law of nature, without asking leave, or depending upon the will of any other men' (Locke, *Civil Government*, chap. ii).

(2) More specifically, the state of nature is the condition of things (a) in which men found themselves before the existence of a common government and legislation: there was then no law but the law of NATURE (q. v.); (b) in which nations stand towards each other now, there being no common government.

The expression occurs in Grotius in both senses. The state before government has been variously conceived as (by Hobbes) a war of all against all, or (by Locke and Rousseau) a state of disorder, but possibly peaceful.

(F.H.G.—J.B.)

The distinction of state of nature from that of culture appears first in the Cynics (the conception, e. g., that Prometheus, the culture-bringer, was rightly punished).

(K.G.)

The chief controversies of political science have raged around the concept of 'a state of nature.' To understand these it is necessary to subdivide the topic as follows: (1) Does the term mean a state in which mankind actually was before governments existed? (2) In a state of nature are men equal or unequal? (3) In a state of nature are men alike or unlike? (4) In a state of nature are men sympathetic, affectionate, tolerant, and just, or are they quarrelsome, treacherous, and merciless? By systematically finding the answers that the great political writers have given, explicitly or by implication, to these questions, we can see exactly wherein their theories differed or agreed; otherwise they are a hopeless confusion. (1) No writer of consequence has seriously regarded the actual state of man before governments arose as of any real importance for political theory now. The language used by Hobbes, Locke, and others has continually referred to an

imaginary pre-political man, but the real question under discussion has always been, given human nature as we know it, what would men do, and how would they live, if they were not subject to government? (2, 3 and 4) Plato, Aristotle, and all political writers to and including Machiavelli, assumed that men are by nature unequal (even though kindred), and that therefore governments inevitably arise and have their justification in the natural supremacy of the strong over the weak, of the wise over the foolish. In Hooker, *Ecclesiastical Polity*, Bk. I (1594), we have a totally different conception. The men who dwell together in one place are not only substantially of one kin, but are also substantially equal. They are endowed with natural affection and desire one another's good will. 'My desire, therefore, to be loved of my equals in nature, as much as possibly may be, imposeth upon me a natural duty of bearing to themward fully the like affection; from which relation of equality between ourselves and them that are as ourselves, what several rules and canons natural reason hath drawn for direction of life, no man is ignorant' (*Eccl. Pol.*, Lib. I). Government therefore, according to Hooker, is a convenience rather than an imperative necessity; it may be modified or reformed; and it may be held to a strict conformity to that natural justice which is anterior to it. Hobbes, like Hooker, regards men as substantially equal, but, unlike Hooker, he conceives of them as being of widely different minds, and as moved by conflicting interests. Consequently, 'men have no pleasure (but, on the contrary, a great deal of grief) in keeping company, where there is no power able to overawe them all' (*Leviathan*, chap. xiii). Accordingly, a state of nature is a state of war, of every man against every man. Government therefore is instituted to stop extermination, and the compact between subjects and sovereign is inviolable. The subjects, in surrendering their natural freedom, have surrendered their power to amend, and they cannot require the sovereign to conform to the principles of an antecedent natural justice, because there never were any. The sovereign originates justice and is not conditioned by it. Locke gets back to the conceptions of Hooker, and develops them. The state of nature he conceives as 'a state also of equality, wherein all the power and jurisdiction is reciprocal, no one having more than another; there being nothing more evident than that creatures of the same species and

rank, promiscuously born to all the same advantages of nature, and the use of the same faculties, should also be equal one amongst others without subordination or subjection' (*Civil Government*, chap. ii). Such a state of nature 'has a law of nature to govern it, which obliges every one; and reason, which is that law, teaches all mankind, who will but consult it, that, being all equal and independent, no one ought to harm another in his life, health, liberty, or possessions' (*ibid.*). Governments therefore are instituted not to create justice, but only to formulate and administer it; and they must themselves conform to the natural justice of a state of nature. Subjects may always appeal from civil government to natural justice, and therefore may amend, reform, or overthrow their governments.

In the light of modern sociology the reconciliation of these conflicting views is not difficult. In the most homogeneous populations there are enough inequalities of strength and wisdom to establish relations of supremacy and subordination, and to ensure the evolution of government. If the population is exceedingly heterogeneous the natural relations of men tend towards the type described by Hobbes, and government approaches absolutism. This is as true of majority rule in a nominal democracy as of personal rule in a monarchy. If the population becomes highly homogeneous, above all in thought, sympathies, and purposes, and if a relative equality prevails, spontaneous social relations are on the whole friendly, tolerant, and just. It is recognized that positive law must conform to ethical standards, and governments are made liberal and constitutional. Hooker and Locke have never received due credit for their penetration in perceiving that natural society and natural justice presuppose equality and homogeneity in the population, and above all, like-mindedness.

Literature: PLATO, *The Republic*, and *The Laws*; ARISTOTLE, *The Politics*; MACHIAVELLI, *Il Principe* (1532); HOOKER, *Eccles. Polity* (1594); GROTIUS, *De Jure Belli et Pacis* (1625); HOBBS, *De Corpore Politico* (1650), and *The Leviathan* (1651); LOCKE, *Civil Government* (1690); ROUSSEAU, *Du Contrat Social* (1762). (F.H.G.)

Static Economics [Gr. *στατικός*, standing, causing to stand]: Ger. *statische Oekonomie*; Fr. *économie statique*; Ital. *economia statica*. (1) In the strict sense, that part of economic science which deals with quantities, and not with rates per unit of time.

(2) In the popular but less correct sense, all economic analysis which assumes a stationary social structure, so that we can assume small variations of single elements, and trace a readjustment of the disturbed equilibrium. Cf. SOCIOLOGY.

There is a tendency among the followers of the Austrian school, and in fact among all those who use modern mathematical methods in economics, to treat kinetic problems by methods of statical analysis—to assume that an equilibrium expressed in terms of *rates* of income, supply, or demand, is synonymous with an equilibrium of pure quantities in the same ratios, and that a discussion of the effect of a small variation in one of these quantities in producing a new equilibrium can be carried over into terms of rates by a simple reintroduction of the time factor. By this method problems of DISTRIBUTION (q. v.) are artificially simplified and incorrectly solved. (A.T.H.)

Static Sensation: Ger. *statische Empfindung*; Fr. *sensation statique*; Ital. *sensazione statica*. Sensation arising in connection with bodily position. (J.M.B.)

Although such knowledge may arise from the visual and 'tactual' end-organs, it is probable that the semicircular canals and vestibule of the internal ear (the end-organs of the vestibular branch of the n. acusticus) constitute an organ of reflex orientation, regulating the posture and movements of the body, and especially of the head. There seems to be no doubt, further, that the sensation quality of dizziness or giddiness (not to be confused with nausea or sickness) is furnished by some part of this organ: for the rest, its sense functions are still a matter of dispute. Nor are the mechanics of the organ, and the functional interrelation of its two main divisions, as yet fully made out.

The best hypothesis, at the present time, is probably that which separates the functions of vestibule and canals. The otoliths of the vestibule may be supposed, by exerting different pressures in different directions, to inform us of progressive movement in a right line. The 'information' may be conveyed reflexly, or by way of a 'pressure' sensation: the latter theory is in accord with the original function of the otolith sac as an organ for the apprehension of jar or shake, a 'preaural ear.' The canals and ampullae would then be the organ of orientation, and especially of orientation after rotation. The giddiness sensation may be mediated by

ciliary movements of the hairs of the hair-cells, such movements naturally varying with change of the pressure of the endolymph. Cf. DIZZINESS, EQUILIBRIUM, KINAESTHETIC SENSATION, ORIENTATION, POSITION, ROTATION SENSATION, and ILLUSIONS OF MOTION AND MOVEMENT.

Literature: KÜLPE, *Outlines of Psychol.*, § 23; WUNDT, *Physiol. Psychol.* (4th ed.), ii. 27; SANFORD, *Course in Exper. Psychol.*, expts. 45-51; Y. DELAGE, *Études expérimentales sur les illusions statiques et dynamiques de direction*, *Arch. de Zool. Expér.*, iv. (2) 525 ff.; WARREN, *Sensations of Rotation*, *Psychol. Rev.*, ii. 273 ff.; E. MACH, *On Sensations of Orientation*, *Monist* (1897); and *Bewegungsempfindungen* (1875); C. KÖNIG, *Étude expérimentale des canaux semi-circulaires* (1897); KREIDL, *Pflüger's Archiv*, li; LOEB, *ibid.*, 1891; BREUER, *K. k. Ges. d. Aerzte in Wien*, Nov. 14, 1873; CYON, *Recherches sur les fonctions des canaux semi-circulaires*, 1878; CRUM-BROWN, *J. of Anat. and Physiol.*, viii; GRASSET, *Malad. de l'équilibre* (1901).

(E.B.T.)

Statics: Ger. *Statik*; Fr. *statique*; Ital. *statica*. The science which treats of the conditions of physical equilibrium, including the laws of action of forces so related as to produce equilibrium.

(S.N.)

Statistics [Lat. *status*, state]: Ger. *Statistik*; Fr. *statistique*; Ital. *statistica*. The systematic observation and treatment of facts on the basis of their relative numbers. (J.M.B.)

The study of statistics as a whole is usually divided into two branches: theoretical and practical statistics. Theoretical statistics are concerned with the domain of statistics in general, and with the principles, methods, and technique of statistical inquiry. Practical statistics deal with the statistical material which is presented to us in the various departments of fact, social life, &c.; such, for instance, as the statistics of population or demography, the statistics of trade, the statistics of pauperism, educational statistics, political statistics, judicial statistics, &c. For illustrations see VARIATION (statistical treatment of), and MORAL STATISTICS (also for literature).

(W.D.M.)

Statue of Condillac. Condillac, in his *Traité des Sensations* (1754), popularized Locke's theory of the origin of knowledge from 'sensation,' eliminating Locke's 'reflection.' In illustration of the process, he employed the fiction of a statue, at first without mind, which receives the gift of the senses one

after the other, beginning with smell; and attempted to show how the mere presence of these sensations would generate all mental processes and products. The presence of the sensation equals perception; the stronger one gives attention; recurrence of a former one, memory; the practically simultaneous presence of an old and new one, judgment (comparison), &c.; while the sense of touch carries with it the consciousness of objectivity. This allegory of the statue became a favourite literary device of the sensationalists. (J.D.)

It may be said that the one thing which *would* be true of such a statue—that it would move if endowed with sensation!—was not asserted of it by Condillac. (J.M.B., J.D.)

Status [Lat.]: Ger. *Zustand*; Fr. *état*; Ital. *stato*. The class relation in which a person stands before the law to others or to the state; the aggregate of rights and duties attached by law to a person as one of a certain class (Markby's *Elements of Law*, chap. iv. § 177; Austin on *Jurisprudence*, Lect. xl; Anson's *Principles of Contract*, 328). This person cannot by contract vary these legal rights and duties. 'If he could, his private agreements would outweigh the law of the land' (Freeman's Appeal, 68 Conn. Law Reports, 539; Mitchell v. First National Bank, 180 United States Reports, 476).

Status is one of the first things recognized or defined by law. The relations of men to each other are determined by status before they are determined by contract.

See *Dig.*, i. 5, *De statu hominum*; 6, *De his qui sui vel alieni iuris sunt*; 7, *De adoptionibus*, &c.

Literature: PUFFENDORF, *De Officio Hominis et Civis*, ii. chap. i, 'De Statu Hominum naturali'; HEINECCIUS, *Elementa Iuris Naturae et Gentium*, Lib. II. chap. i.; FIORE, *Private Int. Law*, i. § 41 ff.; VON BAR, *Theorie u. Praxis des internationalen Privatrechts*, i. § 133 ff., ii. § 421. (S.E.B.)

Status (social): see SOCIAL STATUS.

Statute [Lat. *statutum*]: Ger. (1) *Statut*, (2) *Verordnung*, (3) *Gesetz*; Fr. (1) *statut*, (2, 3) *loi*; Ital. (1) *legge scritta, atto del parlamento*, (2, 3) *legge, statuto*. (1) A law expressed in writing, enacted by the sovereign legislative authority of a state.

(2) One of the permanent rules prescribed by the proper authority for the government of a corporation of a charitable or quasi-public character.

(3) As used by civilians: any kind of law or governmental regulation, and each of its

commands or prohibitions (Merlin, *Répertoire de Jurisprudence*, 'Statut'). *Real statute*: one which concerns property, and persons only as related to property. *Personal statute*: one which concerns persons, and property only as coincident, e.g. one dealing with questions of *status*. *Declaratory statute*: one declaring what the law on some point previously was. *Remedial statute*: one giving a remedy. *Penal statute*: one directing or forbidding certain acts under a penalty. *Statute law*: law created by statute, as distinguished from natural, customary, or unwritten law.

Literature: MAINE, *Ancient Law*, and *Early Hist. of Inst.*; FOELIX, *Traité du Droit International Privé*, i. chap. iv. (S.E.B.)

Steffens, Henrik. (1773-1845.) Born in Norway, and educated in Denmark and at Copenhagen in theology and science, he became intimately acquainted (1794) with Schelling and his philosophy of nature. Returned to Denmark, 1802, and began his work as an author. Professor of natural science at Halle, 1804; at Breslau, 1811; and at Berlin, 1831, until his death. He was first a Spenerian pietist, then an Old Lutheran, and finally an advocate of Schleiermacher's philosophy.

Stereoscope [Gr. στερεός, solid, + σκοπεῖν, to see]: see STEREOSCOPIC VISION.

Stereoscopic Vision: Ger. *stereoskopisches Sehen*; Fr. *vision stéréoscopique*; Ital. *visione stereoscopica*. Vision with a stereoscope; a binocular instrument which presents to each eye its own plane picture of a tridimensional object. The conditions of the depth perception can, evidently, be exaggerated in it, since two pictures may be made of the same object from two points which are much further apart than are the two eyes. (E.B.T.)

A pair of images of this sort gives the perfect impression of solidity when momentarily illuminated by the electric spark; in free stereoscopy (where diagrams are combined by fixating a near or a far point and detaching the accommodation of the eyes from its ordinary close association with convergence) the relief may be reversed according as the point of fixation is in front of or behind the plane of the paper; it has been shown by Schön (*Arch. f. Ophthalm.*, xxii, xxiv) that an object seen by double images may be transferred from within to without the horopter circle, and reversely, by altering the relative brightness of its nasal and temporal half-images. From all this it follows (and most conclusively from the last consideration) that differences in retinal images are sufficient of them-

selves to mediate the perception of solidity (Wundt, *Physiol. Psychol.*, 4th ed., ii. 227).

There are other methods by which pictures in two dimensions can be represented to the eye in relief. (1) If a right-hand view in red is superimposed in the printing upon a left-hand view in blue, and if the eyes are furnished with spectacles consisting of blue glass for the right eye and red glass for the left eye, two black images are produced which are suitable for binocular fusion into a single three-dimensional impression (method invented by L. D. du Haumont of Algiers; materials and slides sold by the Comptoir Suisse de Photographie, Geneva, and by Williams, Brown, & Earle, Philadelphia). (2) Polarized light also furnishes a method of giving different appropriate images to the two eyes, and, like the last-mentioned, it is adapted to representation in the lecture room. By means of a double lantern, two pictures are thrown together upon a screen by two beams of white light polarized in planes at right angles to each other, and each person in the audience is furnished with eye-glasses consisting of a pair of analysers. (This apparatus was invented by, and may be obtained from, John Anderton, of Birmingham, England.) (C.L.F.)

The reflecting stereoscope was invented by Wheatstone (described 1833 and 1838); the current form of the refracting stereoscope (also first described by Wheatstone) is due to Brewster (1843).

Literature: HELMHOLTZ, *Physiol. Optik* (2nd ed.), 782 ff., &c.; E. B. TITCHENER, *Exper. Psychol.*, I. ii. (1901) 257 ff. On free stereoscopy see SANFORD, *Course in Exper. Psychol.*, expt. 212; on stereoscopy by difference in colour, *ibid.*, expt. 221. (E.B.T.)

Sterility [Lat. *sterilis*, barren]: Ger. *Unfruchtbarkeit*; Fr. *stérilité*; Ital. *sterilità*, *infecondità*. The condition of not producing young; infertility.

In botany, male flowers (having stamens only) are termed sterile. In female animals sterility may be due to inability to produce ova, or in the higher forms to inability to sustain the ova until birth, or to some obstruction to the actual impregnation of the ova. (C.S.M.)

The principal biological question in connection with sterility is that of the mutual infertility of species with one another. Darwin supposed this sterility of species *inter se* to be a result of divergent evolution produced by other causes; Romanes reverses the case, and in his hypothesis of PHYSIOLOGICAL SELECTION (q. v.) makes variations towards

sterility (i. e. relative infertility) the beginning of divergent lines of evolution, which issue in new species. Pearson has utilized the opposite sort of variation, i. e. towards increased FERTILITY (q. v.), in his theory of REPRODUCTIVE SELECTION (q. v.). Cf. NATURAL SELECTION, ad fin. (J.M.B.)

Stewart, Dugald. (1753-1828.) Born at Edinburgh, he studied there and at Glasgow. Assistant professor in mathematics at Edinburgh, 1774; succeeded his father in that chair, 1785, and was the same year transferred to the chair of moral philosophy; resigned his chair in 1810 on account of ill health, and retired to his seat on the Firth of Forth, where he devoted himself to literature until his death. See SCOTTISH PHILOSOPHY, and REALISM (natural).

Sthenic [Gr. *σθενος*, strength]: Ger. *sthenisch*; Fr. *sthénique*; Ital. *stenico*. (1) Energetic; characterized by vigour of function. Also used as synonym of stimulating. Asthenic is equivalent to weak, feeble.

(2) Sthenic diseases are those attended with a morbid increase of vital action, and are thus opposed to states of debility. (J.J.)

Stigma [Gr. *στίγμα*, brand or mark]: Ger. *Stigma*; Fr. *stigmaté*; Ital. *stimate*. (1) In mental pathology: a mark of degeneration or neurotic diathesis.

Anatomical or teratological stigmata (stuntedness, malformations, asymmetries of body, peculiarities of hair, of the ear, of the limbs, feminism, persistence of infantile characteristics, &c.) are distinguished from functional stigmata (backward development of speech or locomotion, anomalies of voice, of movements, absence of reflexes, sexual perversions, optical anomalies such as strabismus, colour blindness, &c.). See DEGENERATION and literature there cited.

(2) Patches on the skin in the form of inflammation or drops of blood produced by suggestion. Such phenomena are observed in extreme cases of HYPNOSIS (q. v.) and HYSTERIA (q. v.) and in religious ecstasy. One of the best known cases is that of Louise Lateau.

Literature: D. HACK TUKE, *Influence of the Mind on the Body* (2nd ed., 1884), i. 119-26, and references there given; the literature of HYPNOSIS. (J.J.)

Stimulant [Lat. *stimulare*, to prick]: Ger. *Reizmittel*; Fr. *stimulant*; Ital. *stimolante*. Any condition or substance that temporarily quickens the natural function of a part or organ.

In addition to this general sense of the term (including physical agencies, such as warmth, cold, electricity, and mental excitement, such as joy, hope), stimulant is used in a special sense to refer particularly to the action of drugs on the nervous system. Such action may in turn be local or general and may affect one group of functions more than another. Among such stimulants alcohol is practically the most important. See ALCOHOLISM, INTOXICATION, and PSYCHIC EFFECT OF DRUGS. (J.J.)

Stimulation (1) and (2) **Stimulus** [Lat. *stimulus*, a goad]: Ger. (1) *Reizung*, (2) *Reiz*; Fr. (1) *excitation*, (2) *stimulus, excitant*; Ital. (1) *eccitamento*, (2) *stimolo*. The cause of a nervous excitation which is attended (or followed) by a change in consciousness is a stimulus, and the process set up in a terminal organ by the action of a stimulus is the stimulation. The stimulus may be physical or physiological; the stimulation is always physiological. Cf. ORGANIC SENSATION, and NERVE STIMULATION AND CONDUCTION.

The psychological stimulus is evidently a subform of the physiological, standing to the latter as the psychophysical bodily process stands to the group of bodily processes at large. Stimuli have been classified as internal and external, mechanical and chemical, adequate and inadequate, &c. (E.B.T.)

WEBER'S LAW (q. v.) is an exact formulation of the relation of stimulus to sensation, and is sometimes called 'law of stimulus' or of 'stimulus intensity.' (J.M.B.)

Stimulus: see STIMULATION.

Stirp [Lat. *stirps*, root, race, stock]: Ger. *Stamm* (in use, but not exact), *Rassenanlage* (Barth); Fr. same as Eng. (used by Delage); Ital. *stirpe* (in use, but not exact—E.M.). A term suggested by Francis Galton 'to express the sum-total of the germs, gemmules, or whatever they may be called, which are to be found in the newly fertilized ovum.'

The term was suggested in the paper cited below. Although a modified PANGENESIS (q. v.) is allowed to play some part in heredity, the main stress is laid on the handing on of 'stirp,' and much of the argument is on the lines since developed by Weismann. The conception is practically that of 'stock' as popularly used. Cf. WEISMANNISM.

Literature: F. GALTON, *A Theory of Heredity*, J. Anthropol. Inst. (1876); DELAGE, *Protoplasma et l'Hérédité*, 560 ff.; BROOKS, *The Foundations of Zoology* (1899). (C.L.M.)

Stoa [Gr. *στωά*, a porch]: see Stoics, under SCHOOLS OF GREECE, III.

Stock: see STIRP.

Stoicism: Ger. *Stoicismus*; Fr. *stoïcisme*; Ital. *stoicismo*. The world-view, and the practical attitude towards life, belonging to, or similar to that of, the Stoics. In its practical bearing it is popularly no less than philosophically contrasted with EPICUREANISM (q.v.). See SCHOOLS OF GREECE, III. (J.M.B.)

Stoics: see SCHOOLS OF GREECE, III.

Strabismus [Gr. *στραβισμός*, a squinting]: Ger. *Strabismus*, *Schielen*; Fr. *strabisme*; Ital. *strabismo*. Squinting; a condition in which the visual axes fail to be directed to the same point owing to the inco-ordinate action of certain of the muscles of the eyes. Also termed heterotropia.

It may be due to over-action, weakness, or paralysis of one or more of the ocular muscles. It may be distinguished as (1) convergent, (2) divergent, or (3) complex. In the first case the squinting eye is turned to the nasal side, and its visual axis crosses that of the other eye at a point nearer than the object looked at. Such a condition may result from a paralysis or paresis of one of the external recti muscles, or from excessive development of both internal muscles, the latter being quite commonly associated with hypermetropia. In divergent strabismus (less common) the squinting eye is turned to the temporal side, and its visual axis crosses that of the other eye beyond the object looked at. This is seen in high grades of myopia. In complex cases there may be upward or downward divergences, with or without other inco-ordinations. Various kinds of strabismus are further distinguished according as the affection is constantly resident in one eye or alternates, the eyes having full range of movement, &c.

Literature: HALTHOUSE, Strabismus; NORRIS and OLIVER'S Syst. of Diseases of the Eye. (J.J.)

Strain Sensation: Ger. *Spannungsempfindung*; Fr. *sensation de tension musculaire*, *sensation des tendons*; Ital. *sensazione muscolare di tensione*. See TENDON SENSATION, and cf. EFFORT, MUSCULAR SENSATION, and RESISTANCE SENSATION. (E.B.T.)

Strato. Born at Lampsacus and died at Athens (cir. 270 B.C.). He was a pupil of Theophrastus and a prominent member of the Peripatetic School. See PERIPATETICS.

Strauss, David Friedrich. (1808-74.) Born in Würtemberg, he studied at Blaubeuren and Tübingen, having Baur for a teacher in both places. Repelled by Kant,

and attracted by the mystics and faith philosophers, such as Jacobi, Schelling, Jacob Böhme, and (later) Schleiermacher, he became a devoted disciple of Hegel, joining the radical wing of the Hegelian school, but later showed a tendency to naturalism and materialism.

Stream of Thought: Ger. and Fr. not in use; Ital. *corrente del pensiero* (Ferrari). The conscious life of an individual considered as a series of states continuous in time.

(G.F.S., J.M.B.)

The unity of a thought-process is constituted by the common reference of all its phases to a single object or topic, and on the subjective side by unity and continuity. The stream of consciousness is a stream of thought, so far as it consists of a succession of such processes each having its own unity of object and interest. In the fully developed personal consciousness these successive processes have also more or less thought continuity with each other, inasmuch as their several objects are all parts or aspects of one object—the universe of the world and of the self in its systematic unity. (G.F.S.)

The phrase has been made current by James (*Princ. of Psychol.*), who uses the term for the stream of conscious content in general, to which he applies indifferently the terms 'thought' and 'feeling.' (J.M.B.)

Strength [AS. *streng*, strong]: Ger. *Stärke*, *Kraft*; Fr. *force*, *forces* (physiological); Ital. *forza*. Capacity in general. Usually applied in physiology (1) to the capacity for doing muscular work, measured in lifting, grasping, endurance, &c., and (2) to physical vigour or tone, the opposite of ASTHENIA (q.v.). Cf. TESTS (psychophysical), WORK and LABORATORY AND APPARATUS, III, A. (J.M.B.)

Strength (in logic): see VALIDITY, *passim*.

Stroboscope: see LABORATORY AND APPARATUS, III, B, (a), (g), and ILLUSIONS OF MOTION AND MOVEMENT, I.

Stroke [AS. *strican*, to go]: Ger. *Schlaganfall*; Fr. *attaque*, *ictus*; Ital. *colpo*, *ictus*. A sudden attack; most frequently used for a stroke of PARALYSIS (q.v.). (J.J.)

Structure (organic) [Lat. *structura*, a building]: Ger. *Struktur*, *Bau*, *Aufbau*; Fr. *structure*; Ital. *struttura*. A definite arrangement and connection of parts, with view to a definite function. (C.S.M.)

Struggle for Existence: see EXISTENCE (struggle for), and RIVALRY.

Struggle of the Parts: translation of Roux's Kampf der Theile. See INTRASELECTION. (J.M.B.)

Strümpell, Ludwig. (1812-99.) Born at Schöppenstedt; studied at Königsberg and Leipzig. He taught at Dorpat, first in philosophy, later in pedagogy also; in 1871 he was called to Leipzig as Docent, and in 1872 was made professor. He was a follower of Herbart. His chief work was in the field of pedagogy.

Studies: see INSTRUCTION.

Stupidity [Lat. *stupiditas*, dullness]: Ger. (1) *Stupidität*, (2) *acute Demenz*; Fr. *stupidité*; Ital. *stupidità*. (1) Popularly, dullness of perception or understanding; either as a momentary condition of confusion and lack of usual clearness of thought, or as a temperamental deficiency, with sluggishness of intellectual operations.

(2) Sometimes used (as the French *stupidité*) as synonymous with a state of STUPOR (q. v.) or stupefaction. (J.J.)

Stupor [Lat. *stupor*, insensibility, dullness]: Ger. *Stupor*; Fr. *stupeur*; Ital. *stupore*. (1) In general, a suspension of psychical operations; a condition of intellectual insensibility in which the faculties are deadened or dazed, in which the attention is centred within and not easily aroused, and in which all the mental processes are more or less in abeyance.

General conditions of stupor of greater or less degree may occur in idiocy, in dementia, in the sequence of fluctuations in mania or melancholia, and in circular insanity.

(2) Applied more specifically to two conditions, the one called (a) anergic, the other (b) delusional stupor. (a) The former, termed by Esquirol 'acute dementia,' occurs either as a primary affection or more usually as an intercurrent symptom of mania, epilepsy, melancholia, general paralysis, or other insanity. Such patients seem deprived of all mental and motor energy, and often stand or sit in the same position for hours. Some will strongly resist any attempt to change their positions or attitudes, while others allow their limbs to be placed in and to retain any given posture. Such patients must be fed and cared for in every detail; they seem to have little perception or memory, and on recovery may recall nothing of the entire period of the attack.

(b) The second condition is a true melancholia, and often termed melancholia cum stupore. Here the restraint from action, speech, and food is apt to be the result of direct fear or of a systematized delusion. The patient often remembers on recovery the train of thought which prompted his inactivity and obstinacy. The expression and

attitude are characteristic; the patient sits motionless with clasped hands, fixed vacant stare, the saliva flowing from his half-open mouth, the expression one of vacancy or terror. The movements are torpid, and although terrifying hallucinations may be present, nothing betrays the emotions inspired by the subjective world of terror in which he lives.

It should be added that there is some tendency to abandon the term stupor, except as a symptom, and to refer cases of stupor to KATATONIA (q. v.), to the depressive states of mania, to the transitory stages of epilepsy, and the like.

Literature: WHITWELL, A Study of Stupor, J. of Ment. Sci. (1889), xxxv. 360-73; ZIEHEN, Psychiatrie (1894); KRAEPELIN, Psychiatrie (1901). (J.J.)

Stuttering [imitation of the sound, akin to Ger. *Stottern*]: Ger. *Stottern*; Fr. *bégaiement*; Ital. *intoppiare, incespicare*. A difficulty in speech marked by repeated and uncontrollable spasmodic repetition of the initial part of a syllable (usually an explosive consonant—b, p, d, t).

In general usage, stuttering and stammering are employed almost interchangeably. As a rule stammering is regarded as the more general term, including all speech difficulties of this type, and stuttering as the particular difficulty above defined (cf. STAMMERING). Kussmaul uses *Stottern* as equivalent to stammering in the general sense, and *Stammeln* to indicate the inability to properly pronounce certain letters. Severe *Stammeln* makes speech difficult to understand, and becomes LALLING (q. v.). According to Kussmaul, *Stottern* and *Stammeln* are thus quite distinct: the stutterer has no difficulty with special letters, but cannot voice explosive sounds; the stammerer has no spasm or cramp. Singing may affect stuttering, but not stammering. Increased attention improves the latter, but makes the former worse. As indicated, this distinction is not usually expressed by the same words in English. Cf. SPEECH AND ITS DEFECTS.

Literature: KUSSMAUL, Störungen der Sprache, index 'Stammeln' and 'Stottern'; WYLLIE, Disorders of Speech, chaps. i and vi; LIEBMANN, Vorlesungen über Sprachstörungen, Heft 1 and 2 (1898). (J.J.)

Style [Lat. *stilus*, a writing instrument]: Ger. *Stil*; Fr. *style*; Ital. *stile*. A distinctive character or mode of artistic presentation which controls all the detailed features.

Used in various connections: (1) In general, as good or bad style; idealistic or realistic style. (2) Historically, as classic, Gothic, romantic, Doric styles. (3) With reference to the distinctive traits of the respective arts, as picturesque, sculpturesque, musical, poetic style. (4) Of an individual, as 'in the style of Rembrandt.' (5) As an attribute of value, as 'this artist (or work) has style.'

Literature: VOLKELT, *Aesth. Zeitfragen* (1895), chap. iv; FECHNER, *Vorschule d. Aesth.* (1876), chap. xxvi; GUYAU, *L'Art au point de vue sociologique* (1889), chap. x; RIEGEL, *Die bildenden Künste* (4th ed., 1895), chap. x; SPENCER, *The Philosophy of Style*, Essays, ii; see also the aesthetic publications of VISCHER, KÖSTLIN, SCHASLER, VÉRON, RUSKIN, and CARRIÈRE. (J.H.T.)

Style (in sociology): CUSTOM (q. v.) of the more temporary and ephemeral sort considered as embodying models for imitation; equivalent to mode.

Made an important factor in the imitation theory of social propagation by Tarde (*Lois de l'imitation*). (J.M.B.)

Suarez, Francisco. (1548–1617.) Born of noble family in Grenada, he first studied law. But he entered the Order of Jesus, and devoted himself zealously to theology and philosophy. He taught in Rome, Alcala, Salamanca, and finally in the high school of Coimbra. He died at Lisbon.

Subalternant: see SUBALTERNATION, and OPPOSITION (in logic).

Subalternate: see SUBALTERNATION, and OPPOSITION (in logic).

Subalternation [Lat. *sub* + *alter*, other]: Ger. *Subalternation*; Fr. *subalternation*; Ital. *subalternazione*. The relation of a particular proposition to the universal proposition having the same subject, predicate, and quality, that particular proposition ('Some *S* is—or is not—*P*,' called the *subalternate*) being regarded as following by immediate inference from that universal ('Any or all is—or is not—*P*,' called the *subalternant*). Cf. the diagram given under OPPOSITION (in logic). (C.S.P.)

Subconscious [Lat. *sub*, under, + *cum*, together, + *scire*, to know]: Ger. *halbbewusst*, *unterbewusst*; Fr. *subconscient*; Ital. *subcosciente*, *subconscio*. (1) Not clearly recognized in a present state of consciousness, yet entering into the development of subsequent states of consciousness.

(2) Loosely, the UNCONSCIOUS (q. v.).

(J.M.B., G.F.S.)

It is a least degree of consciousness, required by the law of continuity. We have (a) the conscious process given in attention, the 'focus' of consciousness; (b) the conscious process given in the state of inattention, or in the rest of the 'field' of consciousness; and (c) the subconscious process, which cannot itself attract attention, or be made the object of voluntary attention, until it has attained to stage (b), i. e. until it has ceased to be subconscious.

The facts which have led to the hypothesis of a subconsciousness are (a) the existence of blind conations, organic tendencies, &c., for which no conscious antecedent can be discovered; (b) the mechanization of complicated movements, such as piano-playing; (c) the appearance in 'memory' of ideas which seem to have cropped up of themselves, i. e. have no assignable physical or mental condition; (d) the phenomena of 'secondary' PERSONALITY (q. v.), &c. (E.B.T.)

These distinctions are those of 'degree' of consciousness, as contrasted with that of GRADE (q. v.) of consciousness. It is important that we separate carefully these functional phases in consciousness of content, from the genetic phases in the evolution of mind, whatever analogies may be discovered between them. The diagram given under PARALLELISM (psychophysical) illustrates the two series—the horizontal dotted line at each part has its differences of degree, the vertical dotted line gives differences of grade. In other words, at every grade of consciousness we find distinctions of degree. The term 'stage' (*Stufe*) is sometimes used for grade.

DISPOSITIONS (q. v.) generally are subconscious. Particular experiences often strike us, as when we are occupied with talking, writing, &c., of which we become aware only subsequently; at their occurrence they were subconscious. The subsequent state shows their working in the development of consciousness.

The terms 'subliminal' and 'marginal' are used to characterize the subconscious, both figuratively. That is subliminal which is below a theoretical THRESHOLD (q. v.) of consciousness; that marginal which is not in the focus of the field (after analogy with the field of vision; cf. L.I. Morgan, *Introd. to Compar. Psychol.*). Cf. UNCONSCIOUS, and PERSONALITY (disorders of).

To theories which accept 'unconscious' mind, the subconscious is a transition state through which presentations pass in coming to

the focus (attention). The Herbartian 'mechanism of presentations' (cf. HERBARTIANISM) did much to introduce the notions both of the unconscious and of the subconscious.

The subconscious and 'unconscious' have been hypostatized to do many marvellous things; art has been made the product of the subconscious, the genius has been endowed with a wonder-working 'subconscious'; all of which means that certain mysteries of endowment are not open to introspective analysis—certainly to those of us who have them not—and because they are not spread out on the tablet of consciousness, the subconscious, it is held, plays the greater part.

The terms 'semi-' and 'half-conscious' are loosely used for sub- or vague consciousness.

(E.B.T.—J.M.B.)

Subcontrary [Lat. *sub* + *contra*, against]: Ger. *subconträr*; Fr. *subcontraire*; Ital. *subcontrario*. Two propositions having the same subject and the same predicate, if so related that they can both be true, but cannot both be false, are said to be subcontraries; the relation is called 'subcontrary' OPPOSITION (q.v., with diagram).

The ordinary doctrine is that 'Some *S* is *P*' and 'Some *S* is not *P*' are subcontraries. Thus, 'Some phoenixes rise from their ashes,' and 'Some phoenixes do not rise from their ashes.' But it is better to regard both as false when their subjects are non-existent. (C.S.P.)

Subject (-ive) [Lat. *sub*, under, below, + *iacere*, to throw]: Ger. *Subjekt*, *subjektiv*; Fr. *sujet*, *subjectif*; Ital. *soggetto*, *soggettivo*. (1) The material or content of a thought or discourse, as distinct from that with which the thought is concerned; or OBJECT (q.v.), subject-matter.

(2) Hence, the substantive, the real.

(3) That which is the source and centre of the process of thought, or, more widely, of all psychological processes—the self, ego, mind. In this latter connection *subjective* assumes two meanings: (a) that which is concerned with, or arises from, mental operations, as distinguished from the objective as appertaining to the external and material world; (b) that which is *merely* mental; the illusory; that which lacks validity; that which is not

universal, but confined to some one individual, and to him because of something accidental in his make-up.

In aesthetics, subjective and objective are often opposed to one another as designating two types of criticism: the former, that into which the personality of the author enters; the latter, impersonal, impartial, and more or less cold.

The term begins with a logical sense in Aristotle, which, however, as is usual in Greek thought, has an ontological meaning as well. Logically, it is the subject of a proposition, or of a discourse, that of which something is asserted, *ὑποκείμενον*. But Plato had distinguished between *ἄνωμα* as subject and *ῥῆμα* as predicate, the *ἄνωμα* being the noun or substantive, the constant as against the changing verb, which thus connotes *οὐσία*, essence (*Theaet.* 206, and *Crat.* 399). Aristotle even more explicitly identifies the subject with the substrate, the SUBSTANCE (q.v.)—which, indeed, is only the Latin translation of his *ὑποκείμενον*. This, as indeterminate subject, is *ἄλη*, matter; but as determinate, it is specific individual being, genera being only secondary subjects. It can be subject only, never predicate (see Prantl, *Gesch. d. Logik*, i. 217 ff.; Ueberweg, *Logik*, 143–4; Trendelenburg, *Hist. Beitr.*, i. 13–34, and 54–6). According to the Stoics (Prantl, op. cit., i. 428–32; Trendelenburg, op. cit., 221), the subject is one of the four fundamental categories, and designates being without quality, and, therefore, the ultimate subject of all judgment; the unqualified—the pure universal. As such it is the receptacle in which the formative or seminal reason works.

Here we have a complete fusion of the logical and ontological senses. Apuleius and Capella (Prantl, *Gesch. d. Logik*, i. 581, 676) used the terms *subdita* and *subjectiva* as technical terms for the subject of a proposition or judgment; while Boethius for the first time (so Prantl, loc. cit., i. 696) makes use of the terms *subjectivum* and *praedicatum*. In this form the term passed into scholastic thought. As might be expected, we owe to a nominalist, Occam, the first exposition of the ambiguity of the term, and the distinction of its real form and its logical sense (*ad existentiam*, *ad praedicationem*, Prantl, loc. cit., iii. 368). It is to Scotus that we owe the distinction of subjective and objective in the sense which persisted practically till the time of Baumgarten and Kant.

Scotus identified the two terms with the familiar distinction of Arabian thought of

'first and second intentions'; subjective designating the first intention, concrete substantiality, and objective the second intention, or this thing as constituted through a mental operation (Prantl, iii. 208; also the Index, for other similar uses of the term objective).

Gerson anticipated the modern use of the term, using the phrase 'obiectum vel substratum,' and speaks of an objective reason, 'ratio obiectalis,' which mediates real being in knowledge, 'having two aspects, as it were, an external and an internal' (Prantl, iv. 145). Descartes is true to the scholastic use, objective with him meaning always present to thought (existing *idealiter in intellectu*), and subjective that which is really in the things themselves (*formaliter in se ipsis*; *Medit.*, iii). Eucken (*The Fundamental Concepts of Modern Philosophic Thought*) gives instances of the use of the term in the 18th century prior to Kant. The reversal of meanings in Kant is not hard to understand. The proposition 'I think' has transcendental value: that is to say, it is the function of the self-identity of thought, which, lying at the basis of the categories, is the fundamental *a priori* condition of all knowledge and experience. It cannot be regarded, however, as a thing, as substance, i.e. as soul. 'By this *I* or *he* or *it*, that is, the thing which thinks, nothing is represented beyond a transcendental subject of thoughts = *x*, which is known only through the thoughts that are its predicates' (*Critique of Pure Reason*, 301, Müller's trans.). It is, then, just the absolute subject of all judgments; a significance which clearly enough connects the term with the Aristotelian and logical meaning. But the activity of this function, through the forms of sense and categories of understanding, is necessary to the constitution of objects in experience (of the empirical as distinct from the transcendent object or thing-in-itself); thus, epistemologically considered, if not ontologically, the pure 'I think' or subject has positive significance and value. Thus Kant says: 'If we drop our subject, or the subjective form of our senses, all qualities, all relations of objects in time and space, nay, space and time themselves, would vanish' (ibid., 37). Thus, all the part played by mental activity in constituting empirical objects is repeatedly termed 'subjective.' A double sense is clearly contained here: on one side, this subjective is set over against the objective, when things-in-themselves—reality in its intrinsic nature—are in mind; it is the source of the phenomenal,

of that which has not unconditioned validity—tending towards the sceptical and illusory sense of the term. But, on the other hand, it is constitutive of objects as experienced, and therefore has complete (empirical) objectivity; indeed, because of its universal and necessary character, it is more 'objective' than any law or object found in experience itself.

Kant's successors, by abolishing the thing-in-itself, endeavoured to do away with this ambiguity. They endeavoured to give the pure 'I think,' or unity of thought, a completely objective sense; Kant himself having, indeed, admitted the possibility of the transcendental object being at the same time the subject of thinking (ibid., 311). The subject thus becomes the activity which appears equally in mental processes and in the world of experienced objects. It differs from the soul-substance against which Kant had made his polemic, in being essentially activity rather than substrate, and hence by being considered in its functions in the structure of the world of knowledge, morals, and art, rather than in its isolated subsistence; and as transcending the historical, or empirical, individual mind. Such is its use in Fichte; and Hegel fixed the distinction in a classic way in the introduction to his *Phänomenologie* (*Werke*, 14) by saying the truth, the absolute, was to be apprehended as subject, not as substance. But this technical sense easily passed over into a loose, popular one, in which subject meant mind, soul, though with more psychological implication and with more reference (often very vague, however) to the part played by mind in the process of knowledge. Sir William Hamilton was chiefly influential in making the Kantian distinction of subjective and objective at home in English speech, Cousin and the other followers of German thought, in France. When members of quite the opposite schools, such as Spencer and Comte, adopted the terms, they were thoroughly naturalized, and are now in such general use as practically to have displaced the older senses.

Literature: EUCKEN, *Fundamental Concepts of Modern Philosophic Thought*, chap. i; and *Gesch. d. philos. Terminologie*, 203-4; Franck's *Dict. des Sci. philos.*, iv. 468-71; HAMILTON, ed. of Reid, 97, 221, 806-9; *Discussions on Philos.*, 5, 605; *Metaphysics*, i. 157-62. (J.D.)

Subject (in logic). (1) That of which something is asserted in the form of a proposition; its conventional symbol is *S*. (J.M.B.)

(2) That part of a proposition whose function it is to 'indicate,' or denote, what it is of which the proposition is a SIGN (q. v.), and which it signifies, or indirectly images, in the predicate.

[What follows presents a view of propositions, à propos of 'subject,' developed on the basis of the theory of 'signs'; it may be compared with the more commonly received view given under PROPOSITION. (J.M.B.)]

Whether or not every proposition has a principal subject, and, if so, whether it can or cannot have more than one, will be considered below. A proposition may be defined as a sign which separately indicates its object. For example, a portrait with the proper name of the original written below it is a proposition asserting that so that original looked. If this broad definition of a proposition be accepted, a proposition need not be a symbol. Thus a weathercock 'tells' from which direction the wind blows by virtue of a real relation which it would still have to the wind, even if it were never intended or understood to indicate the wind. It separately indicates the wind because its *construction* is such that it must point to the quarter from which the wind blows; and this construction is distinct from its *position* at any particular time. But what we usually mean by a proposition or judgment is a symbolic proposition, or *symbol*, separately indicating its object. Every subject partakes of the nature of an index, in that its function is the characteristic function of an index, that of forcing the attention upon its object. Yet the subject of a symbolic proposition cannot strictly be an index. When a baby points at a flower and says, 'Pretty,' that is a symbolic proposition; for the word 'pretty' being used, it represents its object only by virtue of a relation to it which it could not have if it were not intended and understood as a sign. The pointing arm, however, which is the subject of this proposition, usually indicates its object only by virtue of a relation to this object, which would still exist, though it were not intended or understood as a sign. But when it enters into the proposition as its subject, it indicates its object in another way. For it cannot be the subject of that symbolic proposition unless it is intended and understood to be so. Its merely being an index of the flower is not enough. It only becomes the subject of the proposition, because its being an index of the flower is evidence that it was *intended* to be. In like manner, all ordinary propositions refer to

the real universe, and usually to the nearer environment. Thus, if somebody rushes into the room and says, 'There is a great fire!' we know he is talking about the neighbourhood and not about the world of the *Arabian Nights' Entertainments*. It is the circumstances under which the proposition is uttered or written which indicate that environment as that which is referred to. But they do so not simply as index of the environment, but as evidence of an intentional relation of the speech to its object, which relation it could not have if it were not intended for a sign. The expressed subject of an ordinary proposition approaches most nearly to the nature of an index when it is a proper name which, although its connection with its object is purely intentional, yet has no reason (or, at least, none is thought of in using it) except the mere desirability of giving the familiar object a designation. Among, or along with, proper names we may put abstractions, which are the names of fictitious individual things, or, more accurately, of individuals whose being consists in the manner of being of something else. A kind of abstractions are individual collections, such as the 'German people.' When the subject is not a proper name, or other designation of an individual within the experience (proximate or remote) of both speaker and auditor, the place of such designation is taken by a virtual precept stating how the hearer is to proceed in order to find an object to which the proposition is intended to refer. If this process does not involve a regular course of experimentation, all cases may be reduced to two with their complications. These are the two cases: first, that in which the auditor is to take any object of a given description, and it is left to him to take any one he likes; and, secondly, the case in which it is stated that a suitable object can be found within a certain range of experience, or among the existent individuals of a certain class. The former gives the *distributed* subject of a *universal* proposition, as 'Any cockatrice lays eggs.' It is not asserted that any cockatrice exists, but only that, if the hearer can find a cockatrice, to that it is intended that the predicate shall be applicable. The other case gives the *undistributed* subject of a *particular* proposition, as 'Some negro albino is handsome.' This implies that there is at least one negro albino. Among complications of these cases we may reckon such subjects as that of the proposition, 'Every fixed star but one is too distant to show a true disk,' and 'There are at least two points

common to all the circles osculating any given curve.' The subject of a universal proposition may be taken to be 'Whatever object in the universe be taken'; thus the proposition about the cockatrice might be expressed: 'Any object in the universe having been taken, it will either not be a cockatrice or it will lay eggs.' So understood, the subject is not *asserted* to exist, but it is well known to exist; for the universe must be understood to be familiar to speaker and hearer, or no communication about it would take place between them; for the universe is only known by experience. The particular proposition may still more naturally be expressed in this way, 'There is something in the universe which is a negro albino that is handsome.' No doubt there are grammatical differences between these ways of stating the fact; but formal logic does not undertake to provide for more than one way of expressing the same fact, unless a second way is requisite for the expression of inferences. The latter mode is, on the whole, preferable. A proposition may have several subjects. Thus the universe of projective geometry being understood, it is a true proposition that 'Whatever individuals *A*, *B*, *C*, and *D* may be, there are individuals *E* and *F*, such that whatever individual *G* may be, there is an individual *H*, and an individual *I*, such that, if *A*, *B*, *C*, and *D* are all straight lines, then *E* and *F* are straight lines, each intersecting *A*, *B*, *C*, and *D*, and *E* and *F* are not coincident; and if *G* is a straight line, not coincident with *E*, and not coincident with *F*, and if *G* intersects *A*, *B*, and *C*, it does not intersect *D*, unless *H* is a one-sheeted hyperboloid of which *A*, *B*, *C*, and *D* are generators, and *J* is a set of generators of *H*, to which *A*, *B*, *C*, and *D* all belong'; or, in our usual phraseology, any four straight lines in space are intersected by just two different straight lines, unless these four straight lines belong to one set of generators of a one-sheeted hyperboloid. Such a proposition is called a relative proposition. The order in which the selection of individuals is made is material when the selections are different in respect to distribution. The proposition may relate to the frequency with which, in the course of ordinary experience, a generic event is of a certain species. De Morgan wishes to erect this into the general type of propositions. But this is to overlook a vital distinction between probability and that which a universal proposition asserts. To say that the probability that a calf will not have

more than six legs is 1, is to say that in the long run, taking calves as they present themselves in experience, the ratio of the number of those with not more than six legs to the total number is 1. But this does not prevent there being any finite number of calves with more legs than six, provided that in the long run, that is, in an endless course of experience, their number remains finite, and does not increase indefinitely. A universal proposition, on the other hand, asserts, for example, that any calf which may exist, without exception, is a vertebrate animal. The universal proposition speaks of experience distributively; the probable, or statistical proposition, speaks of experience collectively. (C.S.P.)

Subject (of experiment): one upon whom a psychological experiment is made.

Other terms in use are 'reagent' and 'reacter' (not recommended), though in a more restricted sense. Cf. also SENSITIVE, and MEDIUM. (J.M.B.)

Subject-consciousness. That phase of consciousness which has objects. See SUBJECT (3), and Subject-self under SELF. (J.M.B.)

Subjective Selection [not in use in the other languages]: see SELECTION (in psychology). The function of selection by or through consciousness, considered as aiding in the survival of the creature which exercises it.

Used by James Ward (*Encyc. Brit.*, 9th ed., art. 'Psychology') as a function of accommodation to and selection of the creature's living environment; and later (*Naturalism and Agnosticism*) as a factor in the evolution of the species. Ward cites ORGANIC SELECTION (q. v.) as invoking the principle along similar lines (*ibid.*), but his article in the *Encyc. Brit.* does not seem to make use of subjective selection as a factor of 'determination' in the theory of descent. Cf. also 'conscious' SELECTION (in biology).

(J.M.B., G.F.S.)

Subjective Sensations: Ger. *subjektive Empfindungen*; Fr. *sensations subjectives*; Ital. *sensazioni subiettive*. Sensations of the special senses arising independently of a stimulus external to the organism.

The use of the term 'subjective' in this connection is open to grave objection. The 'subject' referred to is not the psychological subject or 'self,' but the body as distinguished from its environment. We speak of the retina's own light to denote those visual sensations which arise independently as extra-organic stimulus. Perhaps we might extend

this usage and speak of the ear's own sound, and in general of the 'own' sensations of the various special senses. (G.F.S., J.M.B.)

As illustrating the German usage, cf. the 'subjektive Linien' of Schumann, *Zeitsch. f. Psychol.*, xxiii. 4. (K.G.)

Subjectivism [for deriv. see SUBJECT]: Ger. *Subjektivismus*; Fr. *subjectivisme*; Ital. *soggettivismo*. (1) The theory which denies the possibility of objective knowledge, which limits the mind to consciousness of its own states; as such, equivalent to subjective idealism.

(2) Any theory which attaches great importance to the part played by the subjective factor in constituting experience; e.g. Kantianism in its doctrine of the subjective origin of the forms of perception (space and time) and the categories of conception.

(3) The theory, in ethics, which conceives the aim of morality to be the attainment of states of feeling, pleasure or happiness (Külpe, *Intr. to Philos.*, sects. 14, 30). Cf. OBJECTIVISM.

Subjectivistic products of all sorts (no less than the producers) are said to have 'subjectivity.' (J.D.)

Subjectivity (the, in theology): Ger. *Subjektivität*; Fr. *subjectivisme*; Ital. *soggettivismo*. (1) That tendency which seeks the organ and criteria of religious truth in the intimations of the inner consciousness rather than in history and objective revelations.

The subjective tendency dominates mysticism as distinguished from scholasticism and rationalism; also quietism and all forms of religious profession in which the last appeal is to the inner spirit. The schools of Schleiermacher and Ritschl are subjective in their appeal to Christian consciousness as the immediate source of religious truth. But they are saved from pure subjectivity: Schleiermacher, by his appeal to the historic consciousness of a religious community, and Ritschl, by his appeal to a historic Christ. (A.T.O.)

(2) Any thought which explicitly adopts or defends the subjective standpoint or method has the character of subjectivity; see SUBJECTIVISM. (J.M.B.)

Subject-self: see SELF.

Sublation [Lat. *sub* + *ferre*, to bear]: Ger. see below; Fr. *enlèvement*, *suppression*; Ital. *soppressione*. (1) Removal.

(2) A word proposed to translate Hegel's 'Aufheben.' 'Superseding' has also been

suggested. See HEGEL'S TERMINOLOGY, Glossary, 'Aufheben.' (C.S.P.)

Sublime [Lat. *sublimis*, lofty]: Ger. *erhaben*; Fr. *sublime*; Ital. *sublime*. An aesthetic value in which the primary factor is the presence or suggestion of transcendent vastness or greatness, as of power, heroism, extent in space or time.

It differs from greatness or grandeur in that these are as such capable of being completely grasped or measured; whereas the sublime, while in one aspect apprehended and grasped as a whole, is yet felt as transcending our normal standards of measurement or achievement. Hence two elements emphasized in varying degree by different writers, and probably varying in different observers: (1) a certain baffling of our faculty with feeling of limitation, akin to awe and veneration; (2) a stimulation of our powers and elevation of the self in sympathy with its object.

The element of magnitude in beauty was noted by Aristotle, and given by him a prominent place in tragedy; but the earliest extant determination of the sublime as a distinct conception is in the treatise *περί ὑψους* ascribed to Longinus, but now supposed to be of earlier date (1st century A.D.). In modern times it was given especial prominence by Burke (*Essay on the Sublime and Beautiful*, 1756) and Home (*Elements of Criticism*, 1761), who sought a psychological and physiological explanation.

According to Burke it is caused by 'a mode of terror or pain,' and is contrasted with the beautiful—not a part of it. Kant also distinguished it as a separate category from beauty, making it apply properly only to the mind, not to the object, and giving it a peculiar moral effect in opposing 'the interests of sense.' He distinguished a 'mathematical' sublime of extension in space or time, and a dynamical of power. Most subsequent writers on aesthetics have tended to bring the sublime within the beautiful in the broader sense, i.e. have recognized its aesthetic quality as closely related to beauty.

Literature: KANT, Critique of Judgment, §§ 23 ff.; SEIDL, Gesch. d. Erhabenheitsbegriffs seit Kant (1889); FECHNER, Aesth., xxxii; G. ALLEN, Origin of the Sublime, Mind, iii. 324; SULLY and BAIN, Psychologies; RIBOT, Psychol. des Sentiments (1896), 339 ff. Nearly all the works on aesthetics cited under AESTHETICS and BEAUTY treat the sublime. (J.H.T.)

Subordination (or **Inclusion**, in logic)

[Lat. *sub* + *ordo*, order]: Ger. *Subordination*; Fr. *subordination*; Ital. *subordinazione*. The relation of a smaller or 'lower' to a larger or 'higher' logical class, as of species to GENUS (q. v., in logic). Cf. DIVISION. (J.M.B.)

Subpotency: see PREPOTENCY.

Subsidy [Lat. *subsidiū*, a reserve]: Ger. *Subvention*; Fr. *prime*, *subvention*; Ital. *sussidio*. (1) Older use: a tax granted to meet an emergency, not forming part of the regular budget.

(2) Modern use: payment of public money for a purpose of public importance; especially in aid of shipping or other transportation enterprises.

A subsidy in its modern sense differs from a 'bounty' chiefly in the fact that the public purpose is more distinctly emphasized. Subsidies for shipping are generally accompanied with the condition that the ships of the subsidized lines may be used as transports in case of war, or even armed as cruisers.

Subsidies take many different forms. In England they are given in the shape of mail contracts; and the example of England has been followed by the United States, Germany, and Italy. In France the subsidy is in the form of a mileage allowance for running ships under the national flag, combined with a premium for building the ships in home yards. (A.T.H.)

Subsistence [Lat. *subsistentia*, trans. of Gr. *οὐσίωσις*]: Ger. *Subsistenz*; Fr. *subsistance*; Ital. *sussistenza*. (1) In scholastic thought: the sort of existence of substance in relation to its accidents, the substance being the substratum, the *τὸ ὑποκείμενον* or 'bearer' (Träger) of the accidents. See LATIN AND SCHOLASTIC TERMINOLOGY (11), and cf. Eisler, *Wörterb. d. philos. Begriffe*, 'Subsistenz.'

(2) Used loosely as equivalent to existence. (J.M.B.)

Substance [Lat. *sub*, under, + *stare*, to stand]: Ger. *Substanz*; Fr. *substance*; Ital. *sostanza*. (1) Essence: the important characteristic or constitutive elements in any subject.

(2) Any individual real thing; an entity.

(3) The generalized reality which is manifested in a variety of particular things.

(4) The reality which underlies the properties in any thing, whether mental or material; unknown, while they are known; substrate. The properties have an ambiguous reference: on the one hand, they are supposed to inhere in the substance; on the other, they

are simply the impressions which the unknown substance makes upon our senses; they stand, therefore, with one leg in the object and another in the subject.

SUBJECT (q. v.) and ESSENCE (q. v.) in the early history of the term substance largely divide its meaning between them. Aristotle had used the term *οὐσία* in ways which certainly appear incompatible. On the one hand, it is the concrete, individual thing; it is asserted that it is not possible for it to be the universal—this when he is opposing Platonism. On the other hand, he declares that all science and knowledge are of the universal. Again, it is the mixture, or concrete, of matter and form, the universal realized through being merged in the particular. And again, the substrate or subject (*ὑποκείμενον*) is sometimes defined as pure indeterminate matter. If it is too much to say that the scholastics rolled these meanings into one, they certainly confused substance as individual thing with essence as the real being, or form, found in particular things, and thus prepared the way for the triple modern sense. (1, above) As essence it is the universal and determining real—Descartes and Spinoza—the substantial, as distinct from the attributive or accidental. (4, above) As that which underlies particular things and qualities, it indeed exists, but is unknown; it is simply that which serves as a background and cause, utterly inaccessible in its real nature—Locke and the popular philosophy derived from him—akin to Kant's thing-in-itself. (2, above) Any individual thing or object, having its highest philosophical expression in Leibnitz's monadism. Berkeley acutely sees that Locke's substance is only an abstract idea, and as such, according to his nominalism, meaningless, and so abolishes the substance, matter. Hume repeats the operation upon mind as substance. Kant gives a new meaning to it—that which persists in quantity through a series of temporal changes. See PERMANENCE. (J.D.)

History. (1) The history begins with the assumption of Thales that there is one permanent existent; and he and the other Pre-Socratic philosophers may certainly be said to have conceived their *ἀρχαί* as substances, although they never thought to define expressly the relation in which these stood to their changing forms, and had consequently no name to express this relation. The conception of the *ἀρχή* resembles that of substance, not only in that it is permanent, but also in its affinity to the conception of CAUSE (q. v.,

History), and in that it seems to have been considered to exist more really than the temporary: the latter perhaps is hardly conceived as non-existent, but yet it is of the ἀρχή that you really predicate everything which you seem to be predicating of a complex thing; everything that exists is the ἀρχή. Moreover, there already arises in this period the question whether there is more than one substance; some philosophers holding that there are several, each differing from the other in quality, but permanent and unable to change into the other, whereas the atomists have already reached the conception of a plurality of substances, similar in quality but distinguished by their spatial positions. Plato may be said to have conceived his 'ideas' as substances, since he conceives them as existing, as eternal, as immutable, as the only real existents, and as the causes of all other things. With Aristotle begins the history of the notion 'substances' as an object of definition. The term ὑποκείμενον, of which the Latin translations *suppositum*, *substratum*, and sometimes *subiectum*, were used as equivalent to *substantia* at the beginning of modern philosophy, is used by him in two senses: (a) ὑποκειμένη ὄλη, which denotes that which has the properties possessed by the ἀρχαί of the Pre-Socratic philosophers; (b) the subject of a proposition. The logical subject he generally conceives as something complex, constituted by the union of that essence or form, to which Plato had ascribed ultimate reality, with ὄλη; and it is to this complex that he ascribes the independence (πρώτη οὐσία) usually taken to characterize substance. [The first statement (a) holds of Aristotle's conception of material things; the statement as a whole does not hold, e.g., of the ultimate οὐσία, the Deity, of Bk. Δ of the *Met.* See especially the οὐσίαι ἀνευ ὄλης of c. 6, 1701 b 10, and cf. c. 8, 1074 a 31 f. τὸ δὲ τί ἦν εἶναι οὐκ ἔχει ὄλην τὸ πρῶτον. Ἐντελέχεια γάρ. See Zeller, *Arist.*, 362 ff. Moreover, πρώτη οὐσία is not Aristotle's terminus for 'ultimate reality,' though any οὐσία καθ' αὐτό would be an instance of πρώτη οὐσία; for καμπυλότης = καμπυλότητι εἶναι is given as an illustration of οὐσία πρώτη, in *Met.* 7, 1037 b 2. Cf. Schwegler's note, in loc.—H.N.G.]

Aristotle thus conceived substance as the essential qualities of a thing, distinguished from their essence by the fact that they exist—a fact which he identifies with their union with ὄλη; and his theory thus falls between two stools, since he partially holds the analytic

view of predication, in which the subject is the whole complex thing, but on the other hand rejects part of the attributes which constitute the complete definition of an individual, as mere accidents (συμβεβηκότα), without, however, carrying this process so far as to make the permanent ὄλη ultimate subject. He thus makes it difficult to distinguish substance from essence, and even seems sometimes to speak himself as if, with Plato, he regarded the essence as πρώτη οὐσία. This term is not, however, one of the cardinal terms in his philosophy. The exact Greek equivalent of the Latin *substantia* (ὑπόστασις) seems first to occur as a regular technical term in the Neo-Platonists, with whom it appears to denote the complete definition of an individual, thus carrying out to its logical conclusion the Aristotelian conception of a complex ultimate subject. Curiously enough, however, in the doctrine of the Trinity, ὑπόστασις is the Greek equivalent of the Latin *persona*, whereas οὐσία is rendered by *substantia*.

Thus the confusion between substance and essence, which naturally results from the Aristotelian doctrine of a complex subject, seems to culminate in a complete change of place between substance and essence. Accordingly, from the beginnings of modern philosophy, *substantia*, *suppositum*, and *substratum* are all used as equivalents, and denote both the ultimate logical subject and that which is permanent through change. Descartes, upon these lines, distinguishes two substances, extension and thought, which he considers to be marked out as such by their almost complete causal independence of each other. He cannot, however, consistently with theological orthodoxy, refuse to regard God also as a substance, and the other two as dependent upon him, but dependent in some different way, which is not defined, but for which the term is 'creation,' from that in which a finite effect depends upon its cause. His school generally regarded mind and matter as completely independent of each other, and recognized the anomalous position of God in their definition of substance, defined as 'that which needs the concurrence of God only for its existence.' Spinoza, more consistently, makes God the only substance, defining substance as 'causa sui' or as 'quod in se est et per se concipitur.' Thus extension and thought are reduced by him to two among God's infinite attributes, but it is not explained in what way, if any, God differs from the sum of his attributes: he even speaks of 'Deus

sive omnia eius attributa. Leibnitz defines substance as the ultimate logical subject, and holds that there are an infinite number of substances, each independent of all the rest, but all, nevertheless, dependent upon God.

Locke, Berkeley, Hume tend to regard substance merely as a name for the form in which sensible qualities are combined, and to minimize the importance of the conception; Berkeley, however, allows that the soul is a substance, but without defining what he means thereby. Kant first clearly disengages the notion of that which is permanent through change as the only meaning of substance which is applicable to the existents which we know. He seems, however, to regard the conception of the ultimate logical subject as different from this, and as the proper definition of substance, denying only that any existent conforming to this is accessible to human knowledge. In the philosophy of this century, which tends to consider all the existents known to us as largely, if not wholly, phenomenal, substance has been generally regarded merely as the unknowable real existent, upon which in some sense they depend. (G.E.M.)

Substance (in theology): Ger. *Substanz*; Fr. *substance*; Ital. *sostanza*. That which is one and immutable in being; the ground of properties and changes in things; the divine nature in its essence as transcending personal distinctions. Cf. SUBSTANCE.

The Greek term *οὐσία* is used to express the subsistent element in things and the immutable and unitary divine essence. In his being, God is one and immutable, but in his energizing the distinctions of personality arise. In the thought of the Christian writers, while personality is conceived to be less fundamental than the unitary nature of the divine, yet on the other hand it is not regarded as a mere mode of manifestation. Modalism is a heresy in Christian thought. Cf. HOMOUSIA. (A.T.O.)

Substantialism: see SUBSTANTIALITY THEORY.

Substantiality Theory or **Substantialism** [for deriv. see SUBSTANCE]: Ger. *Substantialitätstheorie*, *Substantialismus*; Fr. *substantialisme*; Ital. *sustanzialismo*. (1) In general, the theory that there are real substances, or distinct entities, underlying phenomenal facts or events.

(2) Its more definite meanings depend upon, and vary with, that which it is opposed to.

(1) As opposed to phenomenalism, it asserts that substances 'mind' and 'matter' exist,

and are known to exist with as much certainty as are particular physical and psychical facts.

Hamilton says: 'Philosophers, as they affirm or deny the authority of consciousness in guaranteeing a substratum or substance to the manifestations of the Ego and Non-Ego, are divided into Realists or Substantialists and into Nihilists or Non-Substantialists' (*Lect. on Metaphys.* i. 294). In a somewhat more limited sense, the term is used to denote the belief of those who hold to a separate self or soul distinct from the phenomena of consciousness, as over against that view which regards the soul as simply the sum-total of conscious activities or modes, the latter school being called 'Actualists' (so Hibben, *Problems of Philos.*, 79), and the theory 'Actuality Theory' (cf. Eisler, *Wörterb. d. philos. Begriffe*, 'Actualitätstheorie,' for numerous citations).

(2) As opposed to the dynamic theory of matter, substantialism holds that matter cannot be resolved into 'centres of force,' or modes of energy, but that mass is a necessary and irreducible concept, over and above that of motion, in considering the physical constitution of the universe. (J.D.)

Substantive and Transitive States (in psychology): Ger. and Fr. not in use; Ital. *stati mentali sostantivi e transitivi* (Ferrari). Substantive states of mind are those which represent sensible terms: nouns, verbs, adjectives, &c.; transitive states are those which represent relations: such things as are expressed by prepositions, conjunctions, &c. 'Relational states' might be a better term for the latter. (W.J.)

The terms were originally used by James, *Princ. of Psychol.*, i. 243 ff. (J.M.B.)

Substantive Law: see ADJECTIVE LAW.

Substitution (in logic) [Lat. *substitutio*]: Ger. *Substituierung*; Fr. *substitution*; Ital. *sostituzione*. (1) Most properly, the removal of a term from a proposition (not necessarily the whole subject or predicate) and the insertion of another term in its place.

The idea that reasoning consists essentially in doing this is an old one, and Jevons maintained that inductive reasoning consists in the substitution of similars. In fact, this would describe presumption, or abduction, in a general way. But there has been great confusion of induction with abduction, and of pure induction with induction affected by other kinds of considerations; cf. PROBABLE REASONING (3). The word in this sense is in wide use among logicians to-day.

(2) Writers on the logic of RELATIVES

(q. v.) follow the mathematicians in the very bad use of this word to signify the operation of changing the order of a finite series of objects, and consequently define it in logic as a totally unlimited dyadic relative of which no individual is relate to two correlates or correlate to two relates; or as a dyadic relative of which every individual is relate to just one correlate and correlate to just one relate. The mathematicians begin to show some symptoms of dissatisfaction with this ill-chosen word; so that logicians would do well to change it at once to *permutation*. Cf. MATHEMATICS, and NUMBER. (C.S.P.)

Substitution (in theology, Christian). That feature of the scheme of redemption in which Jesus Christ is represented as taking the sinner's place, and giving satisfaction for the broken law and purchasing righteousness for the sinner.

The doctrine of substitution presupposes the necessity of propitiation either by the sinner or his substitute. Jesus Christ becomes the expiatory sacrifice that satisfies the requirements of divine justice and renders the exercise of pardoning grace possible, while the obedience of Christ constitutes a righteousness which may be imputed to the sinner for his justification.

Literature: EDWARDS, Sermons on Justification by Faith alone and Wisdom displayed in Salvation, iv (Worcester ed.); ANSELM, *Cur Deus Homo?*; ATHANASIUS, *Contra Arianos*; AUGUSTINE, *De Pecc. Mun.*; OXENHAM, *Doctrine of the Atonement* (1881); SHEDD, *Hist. of Christ. Doctrine*; the Confessions of the Anglican, Lutheran, and Presbyterian churches. Cf. IMPUTATION, and ATONEMENT. (A.T.O.)

Substrate or **Substratum**: see SUBSISTENCE, and cf. SUBSTANCE (4), and ESSENCE.

Subsumption [Lat. *subsumptio*]: Ger. *Subsumtion*; Fr. *subsumption*; Ital. *subsunzione*. A proposition practically putting a case under a rule; as the minor premises of the first figure of SYLLOGISM (q. v.). (C.S.P.)

The 'subsumption theory' is the older logical view that the subject of a proposition is 'subsumed' under the predicate. (K.G.)

Succession and **Duration** [Lat. *sub + cedere*, to yield; and Lat. *durare*, to last]: Ger. (1) *Aufeinanderfolge*, (2) *Dauer*; Fr. (1) *succession*, (2) *durée*; Ital. (1) *successione*, (2) *durata*. Duration and succession are correlated aspects of CHANGE (q. v., 2) in that in which individual IDENTITY (q. v.) is presupposed.

The identity is such as to include in the unity of an object, recognized as the same or different, determinations which cannot be present together. These determinations are then said to succeed each other, and the object which they qualify is said to endure or to have duration. See TIME, TIME PERCEPTION, and TIME SENSE. (G.F.S.—J.M.B.)

The successive determinations of the identical object all form part of its being, irrespective of the question whether they have taken place, are now taking place, or are going to take place. So long as it has not changed in those characters which give it unity and continuity of interest for the subject attending to it, and so constitute it an individual identity for this subject, all its other temporal vicissitudes are integral constituents of its total existence. When it has once changed in those characters which constitute its individual identity, it cannot change any more, because it has ceased to exist. But all other changes are part and parcel of its individual unity, as truly as legs, seat, and back are parts of a chair. We must therefore refuse to accept Kant's dictum that 'only the unchanging changes.' Kant appears to have divided the changing object into two parts, one remaining *materially* identical, i. e. indistinguishably alike, and the other consisting in a series of differences arising and disappearing after one another. On this view the difference cannot be said to change; they only succeed each other. Kant infers that it is the materially identical element or the 'unchanging' which changes. This is not merely a paradox; it is a real absurdity, which only disappears when we substitute the conception of individual for that of material identity.

A materially identical object may *endure* although it does not change. But its duration is always apprehended in relation to some other object (or objects) which does change. The changes necessary to the apprehension of its duration may be merely the sequence of moments of time in the abstract, or they may be merely changes in the psychical state of the subject which takes cognizance of it. (G.F.S.)

Succubus [ML. *succubus*, from *sub + cumbere*, to lie]: Ger. *Succubus*; Fr. *succube*; Ital. *succubo*. An alleged nocturnal demon consorting with human beings.

Witches were tried and convicted of producing offspring through such agency. Cf. WITCHCRAFT. (J.J.)

Suffering [Lat. *sub + ferre*, to bear]: Ger.

Leiden; Fr. *souffrance*; Ital. *dolore, patimento*.
(1) Continued PAIN (q. v.) or UNPLEASANTNESS (q. v.).

(2) Sometimes used instead of passion as a translation of *πάθειν* (*pati*), one of the CATEGORIES (q. v.) of Aristotle. (J.M.B.)

Sufficient Condition and Indispensable Condition (in logic). See NECESSARY AND SUFFICIENT CONDITION.

Sufficient Reason: Ger. *Satz vom zureichenden Grund*; Fr. *principe de raison suffisante*; Ital. *legge della ragione sufficiente*.

(1) This phrase was made a term of philosophy, if not invented, by Leibnitz. In the *Principes de la Nature et de la Grâce*, he says (but this is far from being the first time in which he signalizes the principle): 'It is necessary to resort to metaphysics and to make use of a great principle, not much employed, to the effect that nothing takes place without reason (*rien ne se fait sans raison suffisante*); that is to say, that nothing occurs for which one having sufficient knowledge might not be able to give a reason sufficient to determine why it is as it is and not otherwise.'

It is impossible to understand what Leibnitz means by this, without careful study of his works. There are two difficulties. In the first place, Leibnitz confounded under this phrase two entirely different ideas which he failed to discriminate. In the second place, in order to understand Leibnitz's position here, it is necessary to take into account, on the one hand, the thorough individualistic nominalism, with which he began his philosophical life and never consciously surrendered, and on the other hand his recognition of intellectual relations in the universe of which that nominalistic metaphysics involves the denial. His singular and complicated metaphysics is the outcome of his struggle to reconcile those two incompatible positions.

His sufficient reason is not an efficient cause, but a utility, or, in a broad sense, a final cause. But a nominalist cannot admit that an immediate final cause *exists*. Leibnitz, however, makes it *true*. For a realist, the real is nothing but the immediate object of that which is true. But Leibnitz has another notion of truth. Thus, in a letter to Arnauld (quoted in Latta's accurate and convenient exposition, p. 61, note beginning p. 60), he says: 'Always in every true affirmative proposition, whether necessary or contingent, universal or singular, the notion of the predicate is in some way comprehended in that of the subject, *praedicatum inest subiecto*;

otherwise I know not what truth is'; and in other passages he shows that for him truth is a relation between notions. Yet, as a nominalist, he could not hold that those notions immediately correspond to anything real. Consequently, he does not say that there really is a sufficient reason, but that anybody favourably situated would be able to render a sufficient reason. There is nothing real that corresponds to it immediately. Remotely, the purpose of God may correspond to it. Thus, the world of reality and the world of truth are completely sundered; for the former, Leibnitz is a pure individualistic nominalist; for the latter, on the contrary, he is an intellectualist. When he says, for example, that that which has no sufficient reason is 'necessarily' non-existent, he uses the adverb of logical not of metaphysical modality. He does not hold that real things are either emanations or entelechies of anything corresponding to a sufficient reason, but that is how the mind is affected. But when he comes to the ultimate sufficient reason of contingent truths, which is God, he ceases to draw the distinction between the world of thought and the world of being; and this exception introduces difficulties into his system. But Leibnitz confounds two things under his word 'reason.' The idea which principally governs his doctrine is that a reason is an explanation of the utility of that of which it is a reason; but he includes under the same word any explanation of the logical necessity of the object, the why it follows from a general law. Hence, in many cases, his sufficient reason fulfils the function of an efficient cause. It would be quite possible to quote passages from Leibnitz which conflict with this account of his conception. In order that the reader should apprehend it as he did, it would be requisite that his mind should be in the same unclear condition, which is not possible after one has once attained a superior grade of clearness. We can account for his implicit contradictions, but cannot reproduce his apprehension of them when we once see them to be contradictions.

It is to be remarked that Renouvier and Prat, in their rehabilitation of Leibnitzianism, reject the principle of sufficient reason (*La Nouvelle Monadologie*, 41, note 29).

The principle of sufficient reason may very well be understood to express our natural expectation or hope to find each unexpected phenomenon to be subject to reason and so to be intelligible. But to entertain this hope for each is not necessarily to entertain it for

all. At any rate, it is easy to see that, however strong the tendency may be, it does not amount to any such absolute and inductible necessity as attaches to the law of contradiction, by the side of which Leibnitz and many Germans have placed it. Moreover, however important this tendency of thought and this truth about the universe may be in reference to the development of science, nevertheless, like the principle of the uniformity of nature, its strictly logical application to add force to arguments is very limited indeed. The *modus ponens* and *modus tollens* stand in no need of any such general principle to be perfectly apodictic. It is essential to no broad division of reasoning. As a general rule, when we infer that a particular phenomenon, or set of phenomena, which seemed surprising at first, is to be explained as a consequence of a fact or law not directly observable, the argument is not appreciably strengthened by a separate assumption that the phenomenon has *some* explanation; although there are special cases in which it can be fortified by a similar, but more definite, premise. (C.S.P.)

(2) In logic: 'Every act of thought requires or presupposes another act of thought upon which it is based' (Eisler). This is made one of the fundamental laws of thought by earlier German writers, but English writers do not in general enumerate it as such.

It is more properly regarded as a principle of psychology—the mind requires some ground for its acceptance of any proposed proposition; but this has nothing to do with logic as such. It is hardly a general principle, and when it is active it is incomplete. The non-thinking mind accepts propositions as given to it, and asks for no reasons; if a mind is alert, it seeks not only for the reasons but also for the consequences of things. Every proposition is a centre for backward and forward streamers—the things which prove it and the things which it proves, and one function is no more fundamental and no more compelling than the other. Some propositions are richer in consequences, some excite us more to look for their antecedents; our moral, spatial, and logical intuitions have for us many consequences but no antecedents. The final proposition in which we shall sum up all that it is possible to know about the universe will have very complex grounds for its validity, but it will have no consequences. If the so-called principle of sufficient reason needs to be formulated at all, it should have standing

side by side with it the principle of invariable consequence; here is exhibited, as everywhere else, the fundamental quality of thinking, its duality. Both axioms, in their objective expression, might be expressed in one in the sentence: *Occurrences in the world are linked together in series*; or, *Reasoning is possible*. (C.L.F.)

The principle has played a great rôle in philosophy, many great philosophers taking a hand at giving it formulation. Perhaps the most famous after Leibnitz is Schopenhauer (as below), who develops a 'fourfold root' of the principle, i. e. (1) 'law of reason for Becoming' (*principium rationis sufficientier fiendi*); (2) 'law of reason for Knowledge' (*prin. rat. suff. cognoscendi*); (3) 'law of reason for Being' (*essendi*); (4) 'law of reason for Conduct' (*agendi*), or 'law of Motivation.' These formulations are also given (in detail), together with many citations from other philosophers and logicians, by Eisler, *Wörterb. d. philos. Begriffe*, 'Grund (Satz vom)'. (J.M.B.)

Literature: LATTI, Leibniz (1898); URBAN, Hist. of the Princ. of Suff. Reason, Princeton Contrib. to Philos., i (1898); and Psychol. Rev., iv. (1897) 361; the Histories of Philosophy, 'Leibniz'; SCHOPENHAUER, Die vierfache Wurzel d. zureichenden Grundes; systematic works on logic. (C.S.P., J.M.B.)

Śūfīism [Arab. *Taṣawwuf*, the becoming or being a *Śūfī*. The word is from *śūf*, 'wool'; the equivalent *pashmina-pūsh*, 'clad in wool,' occurring commonly in Persian. Attempts to connect it with *σοφός* in the West, and with the Arabic root *ṣafā*, 'purity,' in the East, must be regarded as purely fanciful. Woollen clothing typifies adherence to the primitive simplicity enjoined by Islām, and rejection of the pomps, vanities, and luxuries of the world; a fact clearly brought out by the historian al-Maṣ'ūdī in his account of the 'orthodox caliphs,' especially in what he says of 'Umar': Ger. *Sufismus*; Fr. *Soufisme*; Ital. *Śūfismo*. The more or less pantheistic and idealistic system of mysticism prevalent in Muḥammadan countries, especially in Persia.

According to their own view, the Śūfīs are simply esoteric Muḥammadans, holding the essential, inner doctrine which lies at the root of Islām. The pantheistic idealism which, more or less clearly, the extreme Śūfīs profess, is based on certain verses of the Qur'ān, such as 'Thou didst not shoot when thou didst shoot, but God shot' (alluding to the Muḥammadan archers at the Battle of Bedr); and on certain

traditions, such as 'God was, and there was nothing beside Him,' and 'I was a Hidden Treasure, and I desired to be known, so I created the Universe that I might be known.' Western writers have been disposed to refer Şúfíism to Indian influences (Buddhism, Vedánta sára) or to Christian influences (a thesis maintained by Whinfield); but so far as it was not an entirely independent growth—the natural reaction of an emotional piety against the formalism of orthodox Islám—it probably owes more to Neo-Platonism than to any other previous system. This point has been admirably worked out by R. A. Nicholson in the Introduction to his *Selected Poems from the Divān-i-Shams-i-Tabriz*. Plotinus and the other Alexandrians were well known to the Arabian philosophers of the early 'Abbásid period, even if their ideas were not introduced into Persia in the 6th century of our era by the Neo-Platonist refugees at the court of Núshírwán, the Sásánian king. Of course, as already hinted, no such external influences are admitted by the Şúfís themselves, who consistently represent themselves as the repositories of the esoteric teaching of the Prophet and his Companions.

In its earlier form (2nd and 3rd centuries after the Flight) the ascetic and ethical sides of Şúfíism were most prominent, and quietism, non-resistance, and a passionate love of God were its most conspicuous features; while the metaphysical, speculative, and pantheistic elements seem to have been superadded at a rather later date under the influence of the so-called Arabian philosophy. The original character of the movement is still commemorated by the various orders of dervishes (Pers. *darvish* = Arab. *faqír*, 'poor') or religious mendicants who abound in the Muhammadan East, and of whom many (especially in Sunnite countries, like Turkey) are pretty orthodox, in contradistinction to the '*urafá*' (pl. of '*áraf*', 'Gnostic') of Persia, who, often undistinguished by any particular garb or distinctive token, are generally thoroughgoing pantheists.

The general theory of the Şúfís as to the nature of God, the universe, and man is as follows. From the philosophical point of view, God is pure Being, the Necessarily-Existent (*Wájibul-wujúd*); from the ethical, Absolute Good (*Khayr-i-mahz*); from the aesthetic, the Eternal Beauty. Now, since the essential nature of beauty is to desire the revelation or manifestation of its attributes and perfections, God caused his reflec-

tion to fall on the mirror of not-being (*adam*), and the reflection thus produced is the phenomenal world or contingent being (*imkán*), which reveals the attributes of God, but does not partake of his substance, being, in fact, a mere phantasm. Of this reflection man is, as it were, the eye. When he loves wisdom, beauty, or goodness, he in reality loves God, and when he recognizes this, and realizes that God is the only reality, he is able to overleap, as it were, his own limitations, and attain the stage of annihilation in God (*faná filláh*), which is the goal of the Şúfí adept or Gnostic. This stage is only reached by a severe spiritual discipline—first an attentive observance of the Sacred Law (*Shari'at*), and then by a patient following of the mystic path (*Tariqat*), which ultimately leads to a knowledge of the truth (*Haqiqat*). Evil is regarded merely as the negation of good, just as darkness is a mere absence of light, not a separate entity. 'There is no absolute evil in the universe,' says the great mystic Jalálu'd-Dín Rûmî; 'Evil is only relative: recognize this also.'

As with many other mystics, the erotic character of many utterances of the Şúfís, especially their poems, is very pronounced, so much so that it is often impossible to separate the allegorical from the literal meaning, especially in the case of lyric poets like Háfiz, with whom Şúfíism was rather a literary fashion than a profound conviction. The Şúfís, moreover, can hardly be regarded as a sect of Islám; their emotional, semi-philosophic, pantheistic idealism is rather a mental habit than a distinctive doctrine, and the very nature of that habit is opposed to any external organization or desire to proselytize. 'The ways unto God,' they say, 'are as the number of the souls (or "breaths") of men'; and they commonly regard all religions as embodiments, more or less clear, of the same central truths. 'All this turmoil and trouble in the world,' says Jámí, 'are from love of him; it hath now become known that the source of this strife is one.' Latitudinarianism and individualism are essential features of the Şúfí doctrine, which is therefore looked on with disfavour not only by orthodox Muhammadans, but also by heterodox sects like the Bábís.

Suggestion (and **-tibility**) [Lat. *suggestio*, from *sub* + *gerere*, to bear]: Ger. *Suggestion*; Fr. *suggestion*; Ital. *suggestione*. (1) ASSOCIATION (q. v.) of ideas: a meaning now generally abandoned.

(2) The coming into the mind from without of a presentation, idea, or any sort of intimation having meaning for consciousness, which effects a lodgment and takes the place it would have if internally aroused by association.

This definition is the broadest possible, making the differentia of suggestion the source of its coming—from without—rather than any peculiarity after it has come into consciousness. This follows Janet (who, however, defines only ‘verbal’ suggestion) as against Wundt, who defines suggestion by its results. (A collection of definitions and their critical examination by the writer will be found in the work cited below.)

Among the more important facts connected with suggestion are (1) the abruptness with which the mental flow is disturbed by the incoming presentation, and the prompt re-accommodation of the mental ‘mass’ to the new situation; (2) a certain ‘narrowing of consciousness’ (*Engerung des Bewusstseins*)

upon the suggested elements, so that direct and restricted motor discharges with muscular movement are more likely to follow; (3) this impairs the normal system with its balance and inhibition, and the higher faculties which depend upon such a synthesis of materials are crippled or held in abeyance; there is thus lack of the ordinary coefficients of belief, lack of the synthesis of free attention, and loss of deliberation and the most capable choice.

It is these effects of suggestion, so thoroughgoing in the mental life, which has made its investigation important in recent psychology. It was first worked out in connection with HYPNOSIS (q. v.) and hypnotism (the ‘suggestion’ theory of the Nancy school). Hypnosis is a state of prolonged or fixed openness to suggestion, called ‘suggestibility.’ It is through the possibility of keeping consciousness in this condition—itsself effected by the suggestion of it—that the nature and workings of suggestion were made the subject of prolonged and repeated experimentation. The results have been gradually brought over into the normal mental life, and suggestion found to belong to the ‘rib-structure’—the real skeleton—of mind.

Among the many distinguishable phases of suggestion—apart from HYPNOSIS (under which see ‘auto-suggestion,’ ‘deferred suggestion,’ ‘criminal suggestion,’ and ‘suggestive therapeutics’), which illustrates them all—are (1) sensori-motor suggestion, movement due to a suggested sensation; (2) ideo-motor suggestion, movement due to a suggested idea; (3) motor-suggestion as such, direct suggestion of movement; (4) sensory suggestion, the suggestion of sensory experience (e. g. that a red light is green); (5) ideal suggestion, suggestion of thoughts, beliefs, &c.; (6) personality suggestion, the peculiar suggestive influence of persons as such; (7) contrary suggestion, the production of effects—actions notably—the contrary of those properly due to what is suggested; (8) negative suggestion or suggestive inhibition, the removal of something from consciousness by suggestion; (9) organic suggestion, the successful suggestion of organic effects; (10) hysterical suggestion, the suggestive conditions of HYSTERIA (q. v.); (11) social suggestion, the normal acceptance of ‘hints’—and more than hints—from the social *milieu*; (12) imitative suggestion, suggestibility to models and copies of all sorts for imitation.

The limits of suggestion in the direction of the 'outside' stimulation which it involves are found in the fact of ordinary truthful experience, which is, of course, just this kind of stimulation: it is hard therefore to draw any line between them. So while the term has been used (by Brown) for association of ideas, said to 'suggest' one another, it has also been used for the incorporation of experience in the system of the mental life (cf. RELATIVE SUGGESTION). It shades off at both ends. And if we demand some mark to distinguish suggestion from ordinary experience, it is hard to find it, except as supplied by objective tests. Outside stimulation, if belonging to the normal world of experiences and not producing illusion or mal-adjustments, is 'experience'; if not fulfilling these requirements, it is 'suggestion.' Hence the tendency to confine the term to stimulations artificially produced—by other persons—which bring more or less disturbance of the normal flow of ideas. But a clap of thunder does this also! Yet there is force enough in the opposing views to lead us to consider the definition well.

Literature: that of HYPNOSIS (especially BERNHEIM; cf. also TRANCE, and CATAPLEXY); SCHMIDKUNZ, Die Suggestion; WUNDT, Hypnotismus u. Suggestion; JANET, Automatismes psychologique; BALDWIN, Ment. Devel. in the Child and the Race; BINET, La Suggestibilité; LIPPS, Suggestion u. Hypnose (1895). See also BIBLIOG. G. 2, h. (J.M.B., G.F.S.)

Suicide [Lat. *sui*, of self, + *caedere*, to kill]: Ger. *Selbstmord*; Fr. *suicide*; Ital. *suicidio*. Intentional self-killing.

Suicide is of interest as having been made the subject both of ethical and legal disquisitions, involving questions of sanity and responsibility, and also of social and criminological study, as involving questions of contagion, motive, and hereditary endowment. Cf. MORAL STATISTICS.

Literature: MORSELLI, Suicide (Eng. trans.); DURKHEIM, Le Suicide (1898). (J.M.B.)

Sui Generis [Lat.]. Of its own peculiar kind, singular, unique.

A phrase used to designate an individual which is the only representative or specimen of its kind, and so identical with the genus, so far as denotation is concerned. (J.D.)

Summation [L. Lat. *summare*, to add up]: Ger. *Summation*; Fr. *sommation* (*addition latente* is also used for (2)—L.M.); Ital. *addizione* (or *somma*) *degli stimoli*. A phenomenon of enhanced psychical stimulation,

including (1) the superposition of stimulus effect upon stimulus effect (summation of effects), and (2) the enhancement of effect by repeated weak stimulation (summation of stimuli).

A psychological illustration of (1) is found in the grey which is seen when a disk of black and white sectors is rotated; an illustration of (2) in the experimental production of TICKLE SENSATION (q. v.). (E.B.T.)

In neurology, summation is a process by which two or more stimuli are united in the production of a single effect. The combination may take place in the path of the stimuli or after their entrance into the central organ. Summation may be due to retarded conductivity or limited conveying capacity, so that stimuli overtake one another. It is possible that summation occurs pre-eminently in the indirect paths of the spinal cord contained in the grey matter (cf. SPINAL CORD), and this is in accord with the theory of Herrick that pain is essentially a result of summation, and Schiff's theory that pain is transmitted via the grey matter of the cord. Recent papers by Head (*Brain*, 1893-4) bring additional evidence of the connection of summation and pain by showing that afferent visceral impulses are limited, when they reach the cord, to the same segments as are concerned with heat and pain stimuli from the periphery. It thus happens that visceral pain is referred to the periphery, as it would not be if continuous tracts for pain passed to the brain. (H.H.)

Literature: WALLER, Human Physiol., 331, 484; WUNDT, Physiol. Psychol. (4th ed.), i. 255, &c.; JAMES, Princ. of Psychol., i. 82, 563, &c.; SANFORD, Course in Exper. Psychol., expts. 17, 31; FRANÇOIS FRANCK, Les fonctions motrices du cerveau. On pain as a summation phenomenon, see VON FREY, Ber. d. k. sächs. Gesell. d. Wiss. (1894), 294. (E.B.T.)

Summation Tone: Ger. *Summationston*; Fr. *son additionnel*; Ital. *suono addizionale*. The summation tone or Helmholtz' combination tone is one of the combination tones; a tone whose vibration rate corresponds to the sum of the vibration rates of the two primaries. See COMBINATION TONE.

It is re-enforced (1) by coincident overtones, (2) by a difference tone of the second order. If n and n^1 are the vibration rates of the two primaries, the summation tone is the difference tone $2n^1 - (n^1 - n)$. Cf. DIFFERENCE TONE. (E.B.T.)

Summists [Lat. *summa*, collection, sum]: Ger. *Summisten*; Fr. *sommistes*; Ital. *som-*

misti. A name applied in SCHOLASTICISM (q. v.) to the successors of Hugo. Their chief aim was to systematize the writings of the great teachers of the Church, and present them as a consistent whole. They thus commence, although only in a formal way, the movement towards the presentation of the content of faith in its unity with reason.

Besides Hugo, Sully, Peter of Lombard, and Alanus are the chief representatives of the school. The name is derived from the fact that Hugo wrote a work entitled *Summa Sententiarum*. See Erdmann, *Hist. of Philos.*, ii. 331-47. (J.D.)

Summum Bonum [Lat.]. HIGHEST GOOD (q. v.); see also GOOD.

Summum Genus [Lat.]. A GENUS (q. v.) which is included under no higher genus.

The predicaments of Aristotle were regarded as *summa genera*. It is true that being was predicated of all, but not in the same sense. (C.S.P.)

Sunnites and Shíites [Arab. *Ahlu's-Sunnat*, 'people of the Sunnat' or 'traditional code' (see MOHAMMEDANISM), *Ahlu'sh-Shi'a*, 'people of the sect' or 'faction' (of 'Alí)]: Ger. *Sunniten und Shi'iten*; Fr. *Sunnites et Shyytes (Chi'ites)*; Ital. *Sumniti e Chiiti*. The names of the two great antagonistic sects of Islám.

As explained in the article MOHAMMEDANISM (q. v.) orthodox Islám is based on (1) the *Qur'an*, or Word of God; (2) the *Hadith*, or words of the Prophet; (3) the *Sunnat*, 'code' or practice of the Prophet and his immediate followers; the two last being a collected and critically edited body of traditions, each vouched for by a chain of veracious and trustworthy authorities (*isnád*) reaching up to the time of the Prophet or 'Companions.' Already in the Prophet's lifetime the germs of dissent were latent, if not patent, amongst his followers, and on his death a serious dispute arose as to the choice and functions of his successor. Abú Bekr was finally elected caliph (Arab. *Khalifa* = vice-gerent, vicar, lieutenant), and was in turn succeeded by 'Umar, 'Uthmán, and 'Alí, these four being the 'orthodox caliphs' (*al-Khulafá ar-ráshidún*) of the Sunnites. 'Alí alone, the Prophet's cousin and son-in-law, was, however, regarded by a certain party as entitled to exercise the functions of supreme spiritual head of Islám. Those who held this view, according to which the first three caliphs were usurpers, were known as the

Shi'a, or 'sect,' of 'Alí. The difference between the Sunnites and Shíites, therefore, appears at first sight to hinge merely on personal considerations; but if we look more closely into the matter, we shall see that this is not so, the former representing the democratic and the latter the monarchical view of government, as applied to the Church. According to the Sunnite view, the caliph was a mere defender of the faith, possessing no supernatural qualities or powers, and any adult and sane Muslim of upright life and sound doctrine was theoretically eligible for the office. To those who, like the Persians, were accustomed not merely to a monarchical government, but to a belief in the divine right of kings in the fullest sense—nay, who were wont to regard their royal family (notably in the Sásánian period, A.D. 226-650) as more or less divine beings, to whom alone appertained the right of ruling—this view could hardly commend itself, and it was natural that in their eyes the descendants of the Prophet alone should be entitled to the spiritual supremacy. Now the Prophet left no male issue, but his daughter Fátima married his cousin 'Alí, and to them were born al-Hasan and al-Husayn, the second and third of the Shíite imáms. The latter, according to a tradition which, whether true or not, is ancient (it is regarded as historical by al-Ya'qúbí, who wrote about A.D. 892), married the daughter of Yezdigird III, the last Sásánian king. Their descendants, amongst whom are included all the remaining imáms, represent, therefore, not merely the Prophet's house, but also the old royal family of Persia, and this, as pointed out by Gobineau, is doubtless one of the chief reasons for the attachment of the Persians to the Shíite cause.

The Shíite imám, again, differs from the Sunnite caliph in that he possesses supernatural virtues and powers which entitle him, and him only, to pronounce authoritative decisions on spiritual matters. Moreover, his non-acceptance by the Muslim community in no wise impairs his right to the imámate, which depends solely on his nomination by his predecessor, or, in the case of the first imám, 'Alí, by the Prophet. The imám, therefore, is, as it were, an infallible, divinely appointed pope, while the caliph is a mere defender of the faith.

Agreeing in these general principles, the Shíites differ as to the number and sequence of their imáms. The two most important

sects were those 'of the Seven' (*sab'î*) and 'of the Twelve' (*ithna 'asharî*), so called from the number of the imáms whom they recognize. At the present day the latter are by far the more numerous, but the interesting and important Isma'ílî sect (including the Assassins of Persia and Syria) attained a high degree of power in the 10th, 11th, and 12th centuries of our era, when the Fátimid or Isma'ílî caliphs ruled in North Africa and Egypt, while the Carmathians continually menaced Arabia and Mesopotamia, and the Assassins terrorized Persia and Syria. The Isma'ílîs still exist in Syria, and are represented by the Khojas of Bombay, the Mullás of Chitrál, and other kindred sects in India, Zanzibar, &c.

The Shí'ites may also be divided into moderate and extreme. The latter (called *Ghulát*) greatly exaggerate the powers of the imáms, whom they often regard as actual emanations of the deity, and frequently hold other doctrines foreign to Islám, such as incarnation, metempsychosis, and the like. The modern Persian sect of the Bábís, or followers of Mirzá 'Alí Muḥammad, the *Báb* or 'Gate' (put to death in 1850), were essentially, in their primitive form, a variety of these *Ghulát*, developed out of the Shaykhí sect founded by Shaykh Aḥmad Aḥsá'í (A. D. 1752-1826), but they have now to a great extent lost this character, and become more practical and ethical in their aims, and less speculative. The Nuṣayrís and Druzes of Syria and the 'Alí-iláhís of Persia also belong to the *Ghulát*.

The Shí'ites believe that the world can never be devoid of an imám, but that at most he is hidden from man's eyes, and will emerge as the Mahdí in the fullness of time to destroy injustice and misbelief, and restore the true faith. Hence the Shí'ite Mahdí is an essentially supernatural being, not, like the Sunnite Mahdí (e.g. the Mahdí of the Soudan), a mere divinely aided champion of Islám. The Sunnites, with their *sunnat*, or body of tradition, have sometimes been compared to the Roman Catholics, and the Shí'ites to the Protestants; but this comparison is quite misleading, since the Shí'ites have an equally large, if not larger, mass of traditions, while their theory of the infallibility of the imám (who is also regarded as 'immaculate,' *ma'sûm*) renders them, of the two sects, more comparable to the Romanists. The hostility between the Sunnites and the Shí'ites is generally (but to a less degree in India than elsewhere) deep

and ineradicable, and has greatly conduced to the weakness of Islám.

BROWNE, *The Bábís of Persia*, J. Roy. Asiatic Soc., 1889; A Traveller's Narrative written to illustrate the Episode of the Báb (2 vols., containing text, trans., appendices, and notes, including, at 173-211, a full bibliog. up to the date of publication, 1891); the New Hist. of Mirzá 'Alí Muḥammad the Báb (trans. from the Persian, 1893); Catalogue of Twenty-seven Bábí MSS. in the J. Roy. Asiatic Soc., 1892; Some Notes on the . . . Ḥurúfî Sect, *ibid.*, 1898; and several important papers by Baron VICTOR ROSEN, of St. Petersburg, and Lieutenant (now Captain) TOURMANSKY, including the text and translation into Russian, with an excellent introduction and notes, of the Kitáb-i-Aqdas ('Most Holy Book') by the latter (1899). (E.G.B.)

Super-: Lat. prefix equivalent to Gr. HYPER- (q. v., 2).

Supererogation (works of, in theology) [Lat. *supererogare*, to pay out in addition]: Ger. *Supererogationswerke, überverdienstliche Werke*; Fr. *surérógation*; Ital. *supererogazione*. Good works done in a state of grace in excess of the strict requirements of the divine law, and constituting a store of merit which may be employed for the benefit of souls in purgatory or for other penitent persons.

The Roman Catholic doctrine of supererogation rests on a distinction between what is

mandatory and what is merely advisory in the divine law. With reference to the latter, man is free, and may lay up a store of merit which under given circumstances may be applied to the benefit of others. The doctrine involves a point of radical difference between the Romish and the Reformed Churches, the latter denying the validity of the distinction on which the doctrine of supererogation rests.

(A.T.O.)

Superhuman [Lat. *super* + *humanus*, human]: Ger. *übermenschlich*; Fr. *surhumain*; Ital. *soprumano*. That which transcends human power or agency. Ordinarily applied to agency or power analogous to that of man and not to the forces or agents of nature.

Superhuman is to be distinguished from supernatural as belonging possibly to the realm of the natural.

(A.T.O.)

Supernatural [Lat. *super* + *natura*, nature]: Ger. *übernatürlich*; Fr. *surnaturel*; Ital. *soprannaturale*. That which in its being or operation transcends the powers or operations of nature, the term nature including the spheres of finite spiritual as well as material forces. Cf. NATURE, and NATURALISM.

The distinction between natural and supernatural must not be confounded with that between natural and spiritual. The spiritual realm is not all supernatural, but includes a cross section of the natural. It is natural in so far as it falls under the operation of ordinary psychic laws. The supernatural is also spiritual. It is the realm of the infinite Spirit, and its operations, in so far as they manifest themselves in the world-series, are properly speaking miraculous.

Literature: see SUPERNATURALISM, NATURALISM (in theology), and MIRACLES. (A.T.O.)

Supernaturalism: Ger. *Supernaturalismus*; Fr. *surnaturalisme*; Ital. *trascendentalismo*. (1) The doctrine that the world, including man, is to be referred, in the last analysis, to a being who in his nature and power transcends the world and cannot be identified with its forces and operations.

(2) The doctrine that Christianity, and the miracles by which it is attested, are of supernatural origin, in the sense that they must be referred to God as their author and cannot be explained by means of natural agencies alone.

The drift of modern thought has been strongly in the direction of naturalism, not in the sense of denying the divine agency in the world, but rather in that of identifying

that agency with the immanent processes of nature. This tendency shows itself, in the realm of Christian theology and history, in the attempt to bring all the facts of Christian doctrine and history under the categories of natural development.

Literature: BUSHNELL, *Nature and the Supernatural*; WM. MCCLINTOCK, *Nat. Hist. of Religion*; MARTINEAU, *Seat of Authority in Religion*; STÄUDLIN, *Gesch. d. Rationalismus u. Supernaturalismus* (1826); F. DE ROUGEMONT, *Les deux cités*, tome ii (1874); M. PERTY, *Sichtbare u. unsichtbare Welt* (1881); ANON., *Supernatural Religion* (1876); LIGHTFOOT, *Supernatural Religion* (1889).

(A.T.O.)

Super-personal: see HYPER- (2).

Superstition [Lat. *superstitio*, from *super-stare*, to stand in amazement and awe]: Ger. *Aberglaube*; Fr. *superstition*; Ital. *superstizione*. Subjectively: the disposition or tendency to ascribe phenomena which admit of natural explanation to occult or supernatural causes; objectively: any system of religious belief or practice which manifests such a tendency.

The English usage of the term is very loose. The German word *Aberglaube* seems to express its meaning more accurately. Superstition is excessive belief or credulity, and arises from the encroachment of faith on the rights of reason and knowledge. In popular usage the term is applied to any system of belief or worship that is conceived to be false or morally degrading, and especially to various forms of polytheism.

(A.T.O.)

Supply and Demand (equation of): Ger. *Angebot und Nachfrage*; Fr. *offre et demande*; Ital. *offerta e domanda*. An economic process by which, through the agency of free competition, price movements result in most fully utilizing the available commodities in market.

(1) As the price of an article increases, the quantity demanded tends to diminish, and the quantity offered tends to increase. There will thus in ordinary cases be a certain price which 'clears the market' and makes the two equal.

(2) This price will, theoretically, be reached by free competition. For, as long as the supply is in excess of the demand, sellers will be in danger of having unsold goods left on their hands, and will compete to force prices down; but if the demand is in excess of the supply, buyers will be in danger of having wants unsatisfied, and their competi-

tion will force prices up, thus producing an equation of supply and demand.

(3) The prices thus fixed tend to be proportionate to the expense of producing the several articles in the market. For if the market price of one article offers a higher rate of profit than the market price of another, investors will gradually abandon the production of the less profitable goods, and put their capital into the line which promises the higher rate, thus increasing the supply and diminishing the price at which it can be sold.

(4) The equation of supply and demand is thus a double process. First, a temporary adjustment of the demand to the supply by the commercial competition of merchants, which lowers (or in the converse case raises) the price until it corresponds to the MARGINAL UTILITY (q.v.); i.e. until it becomes just worth while for consumers to take the whole supply at the price in question. Then there is a more permanent though less accurate and universal adjustment of the supply to the demand, by the industrial competition of investors, which lowers, or raises, the price until it becomes proportionate to the marginal expense of production; i.e. until it becomes just worth while for producers to meet the whole demand at the price in question.

This is the theory of supply and demand as developed by the English political economists from Smith to Cairnes. Far greater precision was given by the adoption of the mathematical form of expression, which we owe, perhaps, most of all to Cournot (1838), Jevons (1871), and Marshall (1890). Cournot's curves, which are in some respects the best, have the form given in the cut. From an origin O lay off on an axis OP successive

prices Op_1, Op_2, Op_3 ; and from the extremity of these abscissae lay off ordinates, on any convenient scale, p_1d_1, p_3d_3 , &c., to represent the quantities demanded at these successive prices. Similarly lay off on the same scale, ordinates p_1s_1, p_3s_3 , &c., to represent the quan-

ties supplied at these prices. The two series of points thus determined will give respectively curves of demand and of supply. The intersection x of these two curves will represent the equation of supply and demand; the price p_2x will be an equilibrium price, towards which, under the action of free competition, there will be a tendency to react in the face of temporary disturbances.

Literature: COURNOT, Recherches sur les Principes mathématiques de la Théorie des Richesses; MARSHALL, Princ. of Economics. For another form of the theory, developed by WALRAS and by CAIRNES, see RECIPROCAL DEMAND. (A.T.H.)

Supposition [Lat. *suppositio*, from *sub* + *ponere*, to place]: Ger. *Voraussetzung*, *Supposition*; Fr. *supposition*; Ital. *supposizione*, *presupposto*. (1) See HYPOTHESIS.

(2) One of the different regular ways in which a name may, in general, be used, so as to denote different objects.

The doctrine of *suppositio* is set forth in the *Summulae* of Petrus Hispanus and in most of the other similar mediaeval textbooks of logic. There are said to be five passions of terms. These are *supponibility*, *ampliability*, *restringibility*, *appellability*, and *distributibility*. The definition of supposition is, 'Suppositio est acceptio termini substantivi pro aliquo.' The term is called the *supponens*, the object the *suppositum*. A supposition is either *common* or *discrete*; the former being that of a general substantive term, the latter that of a proper name, or of a common noun accompanied by a demonstrative pronoun, as *this man*. A common supposition is either *natural* or *accidental*. The natural supposition is the acceptance of a common term for all the objects 'pro quibus aptum natum est participari,' that is, for everything which it is adapted to signify; thus, in 'Man is mortal,' *man* stands for or denotes everything past, present, or future, which the word 'man' was invented to denote. An *accidental* supposition is where the application of a term is limited by its adjunct. Thus, if the verb is in a future or past tense, it will generally be only future or past individuals that are meant. Petrus Hispanus then goes on to divide accidental suppositions into *simple* and *personal*. Another way is to divide suppositions in general into *mixed* and *unmixed*. A supposition may be mixed in two ways. One way is when a compound term consists of words in apposition of which the acceptions are of different kinds, as where we say, 'The word *man* originally meant

a thinker.' Here the acception of 'word' and that of 'man' are of different kinds, the former denoting one of the objects which it was invented to denote, the latter not denoting anything but itself considered in its general employment. The other kind of mixed supposition is that of a term compounded of different nouns so that the denotation of the whole is determined by that of its parts; as where we speak of a *horse's shoe*. But if we say that a river makes a horse-shoe, the supposition is unmixed. Then unmixed supposition is either *material*, *simple*, or *personal*. *Material* supposition is that of a term taken as standing merely for all repetitions of itself, as *man* in the above example. *Material* supposition is either *discrete* or *common*; *discrete* when it refers to a particular instance of the occurrence of the term, when it is referred to as *this* or *that*; *common* when it does not refer to the special occurrence of the term merely. *Common material* supposition is either *determinate* or *confused*. Of the *determinate* a favourite example is '*Sortes est dictio dissyllaba*,' *Sortes* being the form which Socrates takes in logic. *Confused material* supposition is either *merely confused* (*confusa tantum*) or *confused* and *distributive*. Of the former an example is, '*Omne nomen est ly homo*'; of the latter, '*Omne ly homo est nomen*.' *Simple* supposition is that which occurs when we say '*homo est species*' or '*homo convertitur cum visibili*.' As Petrussays: '*Suppositio accidentalis simplex est acceptio termini communis pro re universali significata per ipsum terminum*.' It was also held that the predicate term of an affirmative proposition has a simple supposition, because no *descensus* from it is admissible. Indeed wherever a term was undistributed it seems to have been held to have a simple supposition, except where the term was the subject of a particular proposition. *Personal* supposition is the acception of a general term for its particulars. It is either *determinate* or *confused*. *Determinate personal* supposition is that of the subject of a particular proposition. *Confused personal* supposition is either that of the subject of a universal proposition, which is confused *a necessitate signi*, or that of the predicate, which is confused *a necessitate rei*. The reason is that if '*Every man is an animal*,' every man has his own animality; and it is these animalities for which the predicate supposes (*pro quibus supponit*). In that proposition, '*man*' supposes *distributive et mobilitate*, because descent from it is valid; but '*animal*' *immobilitate*, because descent

from it is not valid. This brief summary gives but a slight idea of the intricacy, weakness, and confusion of the doctrine. (C.S.P.)

Supra. Lat. prefix signifying above or upon. As in '*supraliminal*,' above the THRESHOLD (q. v.). (J.M.B.)

Supralapsarianism [Lat. *super* + *lapsus*, fall]: Ger. *Supralapsarianismus*; Fr. *supralapsarisme*; Ital. *sopralapsarianismo*. That doctrine of the order of the decrees which regards the decree of election as logically preceding those of the Creation and Fall, and as having its sole ground in the sovereign will and pleasure of God. See INFRALAPSARIANISM (also for literature). (A.T.O.)

Supraliminal: see SUPRA, and cf. THRESHOLD.

Supremacy (political): see SOVEREIGNTY.

Supreme Good: HIGHEST GOOD (q. v.); see also GOOD.

Surd: see PHONETICS.

Surdity [Lat. *surditas*, deafness]: Ger. *Taubheit*; Fr. *surdité*; Ital. *sordità*. Deafness. See DEAFNESS and THE DEAF.

Surdi-mutism is a synonym for deaf-mutism, and *surditas verbalis* is a synonym for word-deafness. (J.J.)

Surface [Lat. *supra* + *facies*, face, through Fr.]: Ger. *Oberfläche*; Fr. *surface*; Ital. *superficie*. (1) Of an object: the outside.

(2) In mathematics: a spacial continuum of two dimensions. See SPACE. (J.M.B., H.B.F.)

Surplus Energy Theory: see PLAY, and cf. ART AND ART THEORIES.

Surplus Value [Lat. *super* + *plus*, more]: Ger. *Mehrwerth*; Fr. *plus-value*; Ital. *plus-valenza*, *plus-valore*. Excess of return above labour cost.

According to Marx, the chief exponent of this conception, a capitalist takes money, buys labour, and sells the products of that labour for more than he paid for the labour itself. The labour time spent is (according to Marx, who here follows Aristotle) the true measure of the value of the product. Any excess of price sold above price paid for labour represents a surplus value, created by the labour, but unjustly appropriated by the capitalist. Modern capital he regards as built up out of such appropriation of what really belongs to labour. See VALUE (economic). (A.T.H.)

Survival of the Fittest: see FITTEST (survival of), and EXISTENCE (struggle for).

Suso (or **Seuse**), **Heinrich**. (1295-1366.) Studied at Constance and at Cologne; became a Dominican, 1308. Greatly influenced

by Eckhart, he lived a life of religious seclusion, and of the severest ascetic habits, writing several works of mystical character.

Swallowing Reflex: Ger. *Schluckreflex*; Fr. *mouvement (or réflexe) de déglutition*; Ital. *deglutizione*. The complicated series of semi-volitional and reflex movements performed in carrying moist, solid, or liquid substances through the mouth, pharynx, and oesophagus to the stomach.

Magendie has given the classical account of the organs of deglutition, together with the function of each in the act of swallowing (*Thèse sur les usages du voile du palais*, 1808). He divides the act into three stages: (1) passage of the bolus through the isthmus of the fauces: performed by movements of the tongue, which may be voluntary but are usually reflex, the position of the bolus acting as stimulus; (2) passage of bolus through the pharynx: a pure reflex, consisting on the motor side of rapid and nicely co-ordinated contractions of the pharyngeal muscles, by which the bolus is shot across the air-passages and into the oesophagus; (3) passage of bolus through the oesophagus. The act is completed in about six seconds, of which the peristaltic contraction of the oesophagus takes 4.8 seconds. Kronecker and Meltzer (*Du Bois-Reymond's Arch. f. Physiol.*, 1883, Suppl. 3, 328) studied the act of deglutition by modern methods, and found that the bolus is put under great pressure in the pharynx and literally shot down to the cardiac opening of the stomach, sometimes even forcing open the cardiac sphincter and entering the stomach by initial impetus, the passage through the pharynx and to the cardiac opening taking about 0.1 second. The pressure is largely produced by the simultaneous contraction of the myelo-hyoid and hyoglossus muscles, which pull the larynx upward and forward underneath the bolus and at the same time draw the tongue backward against it.

(C.F.H.)

Swedenborg, Emanuel (and **Swedenborgianism**). (1688-1772.) He was born at Stockholm, the son of the Lutheran bishop, Jesper Swedberg. He was well educated, graduating as Ph.D. at Upsala University. He published in 1709 a little treatise made up of extracts from Seneca and Publius Syrus Minus with his comments, but turned immediately to a scientific life in the lines of mathematics and mechanics, and so successfully that, under the ennobled name of Swedenborg, he became a member of the Commission of

Mines and of the House of Nobles. He spent a year in England to gain a knowledge of 'the progress made in the last one or two centuries.' He was in touch there with astronomers, but was interested in the useful rather than in the theoretical.

Seventy-seven works, of which twenty were in Swedish, the rest in Latin, are classed as scientific by his bibliographers. He introduced the calculus into Sweden. He invented the air-tight stove. He began the science of crystallography. He reasoned out before Franklin the identity of lightning and electricity. He anticipated Laplace in the discovery that planets and planetary motion are derived from the sun. He discovered the animation of the brain. The law of the conservation of energy seems to have been anticipated in his doctrine of action and reaction equal and necessary to life. Among these works the following are of a philosophical and psychological character: *Comparison of Wolff's Ontology and Cosmology with the Author's Principia*; *On the Brain*; *Economy of the Soul's Kingdom*; *Rational Psychology*; and *Kingdom of the Soul considered anatomically and philosophically*.

In the *Principia*, a work in folio with large plates, he fully set forth the nebular theory in 1734. Kant's pamphlet, *Theorie des Himmels*, appeared in 1755, Laplace's *Exposition du Système du Monde* in 1796. Kant's indebtedness to Swedenborg, whom he ridiculed in his *Geisterseher* after having read him extensively and written of him with high praise, has been a subject of investigation by impartial investigators such as Joseph Le Conte, E. S. Holden, and Magnus Nyren. For a summary of the *Principia* the following may suffice.

Part I treats of the origin and laws of motion, their existence being traced from a first natural point down to the formation of a solar vortex, and then to the constitution of the elements and of the three kingdoms of nature. Motive effort tends to a spiral figure. Part II applies the theory of vortical motion to magnetism in order to test the truth of the principles and to explain magnetic phenomena thereby. Part III applies the principles to cosmogony, the origin of the planets from the sun, and their revolutions until they arrived at their present orbits; also to the elements, the motions of which are held to be vortical; also to the laws of the three kingdoms of nature. 'Nature is always alike and cannot be different in largest from what she is in smallest.'

In the works *De Regno Animalium* he analysed the statements of anatomists, avoiding his own observations lest they should be made to favour his views, and dealing with the organs in an ascending series and as the servants of the mind. This brought him to a perception of the constant interaction of the mental and the material or of the spiritual and the natural in man, of which he treated in a small work called *The Hieroglyphic Key of natural and spiritual Arcana*, written in 1741.

In this progress, aloof from theology and pursued uninterrupted by self-seeking, he had reached the point where he must stop or enter the field of the soul's relation to God. He took up the study of the Hebrew Bible, producing in the last thirty years of his life a series of works of about the same number as in the previous stage. These works dealt with the interpretation of Scripture by means of the relation of earthly objects to spiritual realities, the spiritual world as substantial and directly known to him, and the teachings so derived as forming a purified Christianity which will realize the era of the New Jerusalem.

The philosophy of these works is especially set forth in those on *The Love and Wisdom of God*, and on *The Divine Providence*. The former is in five parts, treating of love as the life of man and of God as Love itself. His Wisdom is as the *existere* of his Love, the *esse*. He is Infinite Man. These two qualities in him are distinctly one and are as substance and form. Love by Wisdom creates eternally. Man, like all other creations, is a recipient of life, thus finited, and represents in himself all creation. The Infinite is in time and space, but not of them. The first of creation is the sun of heaven, which animates the spiritual world and fills all degrees of life, which are not continuous but discrete, so that the connection of a higher with a lower degree is that of cause and effect or of correspondence. Matter is the ultimate of creation. Man is born in the lowest degree with power to develop the higher degrees, and this development or regeneration is the history of the race repeated in the individual. It is the first chapter of Genesis repeated in its spiritual meaning. The mind is composed of will and intellect, corresponding to the Divine Love and Wisdom. Evil is man's perversion of love received. Man is preserved free. There is no Divine reprobation. Every one who is in order fulfils his destiny, his own use here and hereafter.

Death severs the correspondence of the

spiritual part of man with the material, and he is thenceforth in his spiritual body a denizen of the spiritual world. Angels are the risen souls who conform to the Divine order; evil spirits are those who oppose that order through self-love, and who therefore live in less freedom. Evil is permitted, but always from a good purpose, and this permission is a part of Providence, which has no other end than the formation of heaven. Though continually led of this Providence man must act as of himself. In the other life, freed from the trammels of space and time, man enjoys the highest form of life of which he is capable, in the best companionship and in the most congenial service of all others. Sex is of the mind in the unequal combination of will and intellect in man and woman, so that an unselfish union of two minds forms the true unit of humanity in both the natural and spiritual worlds. Procreation is only of the natural world. Life hereafter is in an environment which perfectly corresponds with the spirit. All the angels form a grand unit, a *maximus homo*.

The religion of this system is similar. There is one Divine Being. Men first dwelt with him in childlike ignorance and innocence, the Eden of the Bible, the golden age of tradition. As man developed in intelligence he very gradually became wayward, and the loss of his innocence led at length to an evil condition called the Flood. Idolatry with gross rites followed, and man was near losing his humanity. Then the same Fatherliness which had hitherto watched over him took on a nature like his own by virgin maternity, and withstood the rising evil tide, and redeemed man by subduing with love all self-love in that nature. In the order of man's regeneration the Son of Man was glorified, and in him 'dwells the fullness of the Godhead bodily.' In the Divine as in man there is the Trinity, not of persons in a crude sense, but of Love the Father or substance, Wisdom the Son or form, and Creative Life the Holy Spirit or useful activity.

The sacred Scripture is divinely inspired in possessing within its homely exterior a spiritual or prophetic sense fulfilled in the Redeemer (the 'Word made flesh') and in the regenerated soul. The deeper meaning is therefore the creative order or truth in the universe embodied in words, as a soul is in its body. A symbol cannot mean two things, but denotes that which it has as its cause of being, as the face denotes the mind.

Charity, or the law of life, is conformity to order. One's special service is true charity; faith alone is of no avail. Man on account of his past must be turned from controlling self-love and thus born anew. The two sacraments of Baptism and the Eucharist are perfect correspondences, and therefore highly useful as embodying the new life entered upon and continued.

The materialistic misunderstandings of the middle ages, when primitive Christianity was corrupted by priestcraft and strife, supposed a second personal Advent and a physical end of the world. A truer understanding perceives rather the end of that perverted or Babylonian state of things, and a renewal of Christianity by a revelation of the true meaning of the Divine word by means of a well-prepared mind.

Swedenborg regarded himself as having been led all the way towards the accomplishment of this unique service, and in the performance of it he was placid and modest. He published books at his own expense. He put no name on them until near the last. He lived unmarried and frugally. To secure liberty of the press he made several journeys to Amsterdam and London, dying in the latter place. He never attempted to organize his sympathizers. He was still writing on longitude in 1766 after most of his theological works had been published. He said of himself that he had been led over this pathway from 1710 because 'it was necessary that spiritual things should now be understood rationally; therefore I was first introduced into the natural sciences and thus prepared; the dogma that the understanding is to be held under obedience to faith had closed the Church, and what can open it except an understanding enlightened by the Lord?' He also declared that he had received nothing from any one but the Lord through study of the Scriptures.

Literature: of the biographies of Swedenborg that of BENJAMIN WORCESTER (1883) is the best. His works have been issued in the original Latin, in English, and many other languages. The principal books not mentioned above are Heavenly Arcana, Apocalypse Revealed, Heaven and Hell, Doctrines of the New Jerusalem, Intercourse of Soul and Body, Marriage Love, and True Christian Religion. (T.F.W.)

Swoon [ME. *swowen*]: Ger. *Ohnmacht*; Fr. *évanouissement*, *syncope*; Ital. *svenimento*. A faint; loss of consciousness. See SYNCOPE. (J.J.)

Syllogism [Gr. *συλλογισμός*]: Ger. *Syllogismus*, *Schluss*; Fr. *syllogisme*; Ital. *sillogismo*. (1) Syllogism consists in stating in one proposition the truth involved in two non-relative propositions after the elimination of a common term, as

All *a* is *b*;
All *c* is *a*;
(s) ∴ All *c* is *b*.

The first of these propositions (which contains the predicate of the conclusion) is called the major premise; the second, which contains the subject of the conclusion, the minor premise. (C.L.F.)

(2) According to Aristotle and the great body of logicians, a simple syllogism has two premises and a conclusion, and three terms, one of which, the 'middle,' disappears from the conclusion. In the writer's opinion, the limitation to non-relative premises is contrary to usage and to propriety. (C.S.P.)

(3) The sense laid down by Aristotle at the opening of his *Analytics*, 24 b 18, and repeated with verbal accuracy at the beginning of the *Topics* and at the beginning of the *Sophistici Elenchi*, and less formally in the logical part of the *Rhetoric* (A ii. § 9), namely, *συλλογισμός ἐστὶ λόγος ἐν ᾧ τεθέντων τινῶν ἕτερόν τι τῶν κειμένων ἐξ ἀνάγκης συμβαίνει τῷ ταῦτα εἶναι*, 'A syllogism is a symbol (λόγος) in which, some things having been posited, something different from the assumptions necessarily joins itself to them, by being involved in the being of the facts assumed.'

It will be seen that, in this definition (2), no particular stress is placed upon the premises being two in number; although Aristotle is afterwards emphatic in insisting that every syllogism has two premises. The following inference is, on this definition, syllogistic: 'A stands to a lover of B in the relation of benefitting everybody loved by him; hence A benefits B.' The two essential characters are that the inference shall be necessary, and that the fact inferred shall be involved in the very being of the facts premised, regardless of the manner in which those premised facts may have become known. The operation called *colligation* by Whewell, which consists in bringing the different premises together and applying them, the one to another, or to a repetition of itself, in a particular way, wherein lies all that calls for sagacity in deductive reasoning, is then no part of the syllogism. Aristotle seems to say (1 *Anal. Pr.* xxxii) that some necessary inferences are not syllogisms; but the passage is not clear. However, if

colligation is to be excluded from syllogism, then also such an inference as the following will be non-syllogistic: 'Every man is an animal; hence whatever is in a given relation (as for example, 'other than') to every man is in that relation to every animal.'

An argument consisting of a single syllogism is a monosyllogism, one of more than one a polysyllogism, called also *monosyllogistic* and *polysyllogistic proof*.

Trendelenburg, in his *Elementa Logices Aristoteleae*, gives an account of the origin of the word, remarking that συλλογίζεσθαι is properly to conjoin in arithmetical computation or in reasoning. Thus, in the *Philebus*, 41 C, where Jowett translates 'you may infer,' the word means to put together two conclusions already reached and then deduce a further result. In the *Theaetetus*, 186 D, where it is said that ἐπιστήμη does not consist ἐν τοῖς παθήμασι, but ἐν τῷ περὶ ἐκείνων συλλογισμῷ, συλλογισμός is a synonym for what in the *Phaedrus*, 249 B, is called simply λογισμός, "ἐκ πολλῶν ἰὼν αἰσθήσεων εἰς ἓν λογισμῷ ξυναιρούμενον." And Trendelenburg is of opinion that there are in Aristotle traces of the broader meaning, as when he speaks of ὁ ἐξ ἐπαγωγῆς συλλογισμός. Others, however, think that Aristotle's language shows that he drew a distinction between ἐπαγωγή and the syllogism from ἐπαγωγή, the latter being valid only in case of a complete enumeration. Bonitz, however, gives other instances of Aristotle's using the word in a broad sense. The chief of these is in *Rhetoric*, A xi. § 23, where Cope's note quoting a similar passage in the *Poetics* is interesting. Lutoslawski points out that one of Plato's very earliest dialogues, the *Charmides*, 161 A¹, contains a regular syllogism in *Cesare* introduced by the word συλλογισάμενος (160 E). He also remarks that in the *Philebus*, the term μέσση is used in the same technical sense as in Aristotle, and adds: 'If we take into consideration that it would be entirely against Plato's view of literary composition to enumerate all possible figures of syllogism in a dialogue, as is done in Aristotle's treatise, it becomes quite possible and even probable that Aristotle's theory of syllogism was more than prepared by Plato.' Of course this can be no more than a surmise, but it is a reasonable

one, since Plato's mathematical mind would naturally have looked at reasoning in a formal light. At any rate it is almost incredible that any man should have struck out all that is in Aristotle's *Analytics* if the ground had not been prepared. Moreover, Aristotle everywhere exhibits a mind quite unmathematical, so that one cannot but suspect that he received some hints towards a general outline of syllogistic from some source. Yet we cannot, for an instant, doubt Aristotle's veracity in the last chapter of the *Sophistici Elenchi*, where he says of syllogistic: 'Of this subject, on the other hand, there has not been a part cultivated and a part neglected, but nothing whatsoever of it has hitherto existed.... About syllogizing I am aware of absolutely nothing having been previously said [περὶ δὲ τοῦ συλλογίζεσθαι παντελῶς οὐδὲν εἶχομεν πρότερον ἄλλο λέγειν]¹.' (C.S.P.)

[The two sections following are written from the points of view of the two definitions respectively, and reflect current differences of view.—J.M.B.]

(1) Deductive reasoning in general is stating explicitly (in a conclusion) something which has already been implicitly stated either in a single proposition, or in several propositions put together (called the premise, or the premises), thus—

If every point of the line x is equidistant from A and B , and if every point of the line y is equidistant from B and C , it follows that what are points at once of x and of y are equidistant from A , B , and C .

Drawing a conclusion from a single premise is called 'immediate inference'; the conclusion may be equivalent with the premise (that is, it may furnish sufficient ground for recovering the premise)—in this case a mere transformation of the original premise has been per-

¹ Written, as there is strong unpublished ground for thinking, 394 B.C., while Aristotle only went to Athens 368 or 367 B.C. (Grote thinks not till 362 B.C.) All the other dialogues here mentioned are subsequent to Aristotle's joining the school.

¹ It has been argued that Aristotle may here, as it is said he often does, employ the first person plural to mean the students of Plato; and also that πρότερον ἄλλο would not exclude aid from contemporaries. The present writer, without making any particular pretension to philological learning, apprehends that it is quite clear that Aristotle is speaking of himself personally, and that he means to say that no doctrine of the syllogism, in which he now takes the first steps (ὡς ἐκ τούτων ἐξ ἀρχῆς ὑπαρχόντων ἔχειν ἡ μέθοδος), had existed before his *Analytics* and *Topics*. Such hints as he may have received from Plato cannot (the writer believes) have been in Aristotle's memory when he penned those words. But a man does not always know how he originally came by ideas which occupied him at first little, but afterwards more and more, up to almost complete absorption for many long years.

formed; or it may state less than the premise, in which case it may be called an UNDER-STATEMENT (q.v.). If the conclusion is drawn from more than one premise the reasoning is called 'mediate.'

In the example given above, all the terms about which information is given in the premises reappear in the conclusion; but in the most useful form of mediate reasoning, there is involved the dropping of information, and usually of information concerning a term involved in each of the two premises; this may be referred to as the elimination of a middle term. Thus in

A is in the same box with X ;
(r) B is in the same box with X ;
 $\therefore A$ and B are in the same box with each other,

the conclusion is irrespective of the middle term X . If what is desired is information about the relation of A and B to each other, then dropping all information concerning X is the removal of what was burdensome—is a loss which is a gain. Eliminative reasoning may be defined to be the throwing away of information (partly contained in each of two premises) concerning uninteresting terms and saying what remains in one proposition. (If the information which is dropped was contained in one of the premises only, it is simply a case of under-statement.) So we come to the definition (1) of the syllogism: if the relation between the terms involved in an instance of eliminative reasoning is the simple copulative connection expressed in *is* or *implies* (in any of their forms—*a is b*, *Some a is not b*, *That a is b implies that c is d*. See PROPOSITION) the reasoning is called 'syllogism.'

The syllogism is frequently defined as a group of three judgments, of which the last is necessitated by the two preceding, but that does not exclude such an argument as (m), which few persons would consider a syllogism. It is also defined (Lotze) as the union of two judgments to produce a valid third judgment (not consisting in the simple summation of the other two); and by this definition the argument (r) is not excluded. More successfully, the syllogism has been defined in general terms to consist in the applying of a general rule to a special case. The general rule, or law, is the major premise, the special case is the minor premise, and the application is the conclusion:

(t) Rule,
 Case,
 Application.

(The word application, like conclusion and judgment, is unfortunately ambiguous; we should say the applying, the concluding, the judging, for the act, and leave the other words for the product of the act. The term RESULT (q.v.) has also been used.) This definition, of course applies, like the *dictum de omni*, only to the first figure.

It has been argued by many logicians that all reasoning is syllogistic, and by many others that not all reasoning is syllogistic. The solution to the difficulty is this: both contentions are legitimate, but the different parties to the discussion take a different view as to what constitutes the reasoning in a given argument. Thus the argument (r) can be put in the form: If two things are in the same box with a third thing, they are in the same box with each other; but A and B are in the same box with X , and hence, &c., and this, it is said, is surely syllogism. The question, now, is this: Did the reasoning in (r), as first given, consist in the referring, implicitly, to some authorizing principle, or is it characterized by the nature of the authorizing principle referred to? On performing an ordinary syllogism, we have in mind the *dictum de omni* as our legitimizing principle, and in referring to it (instinctively) we are again going through an instance of rule-case-application. Now which constitutes this syllogism—the referring, or the principle referred to? It seems most natural to say the latter, and to conclude, therefore, that the argument (r) is not a syllogism, but an argument corresponding to it, for which the legitimizing principle is a *dictum* concerning the copulative relation 'is in the same box with,' and corresponding in form, in this case, with the *dictum* of Aristotle. There are countless relations of this sort which are transitive (or, as it might better be called, eliminative), and of which the 'principle' is perfectly self-evident to us. There are others, of course, which offer no ground for the elimination of a common term; as, A is longer than X and B is longer than X . Bradley is severe upon that large body of logicians who maintain that all mediate deductive reasoning is syllogistic. [It would seem to be a matter of definition, of the use of a term; there seems to be a large majority in the 'large body,' and the psychology of reasoning appears to lend support to their view.—J.M.B., C.S.P.]

It has been sometimes said that the validity of the syllogism can be made to depend upon the laws of thought, but the assertion that the

sylogistic axiom can be derived from anything else whatever is a contradiction in terms—it can be proved that the syllogism cannot be proved. For proof consists in referring a special case to a general rule, under which it is shown to fall, and that very act has its justification only in the principle of the syllogism. What principles shall be assumed as the fundamental axioms of any branch of knowledge is, to a certain extent, a matter of convenience—frequently, of two, each will entail the other, and it is sufficient to assume either one. But this does not apply to the syllogism; whatever else may be regarded or not regarded as an indispensable assumption, the axiom of the syllogism must always be assumed the first thing of all, for without it nothing can be derived from anything. Various forms of expression in words have been given to this axiom, as the *dictum de omni*—Whatever can be affirmed of the whole can be affirmed of what has been shown to be a part of the whole (as usually given, this applies only to immediate inference, not to the syllogism); or, in terms of pure intention, the *nota notae*—A mark of a mark is a mark of the thing itself. For the syllogism in the second and third figures (with the middle term as predicate, or as subject, of both premises) other principles are needed (Lambert), or those figures can by processes of REDUCTION (q.v.) be brought to the first figure. Wundt gives, as covering mediate inference in general (*r*), what he calls ‘the principle of relation,’ which amounts to this—Things which stand in a relation to a third thing stand in a relation to each other. But this is simply incorrect; if *A* and *B* are each *X*, they need not stand in any direct relation whatever to each other; if *A* is longer than *X* and *B* is longer than *X*, nothing whatever can be affirmed about the relation of *A* to *B*. Relations are too various to permit of any general statement being made about them—some are mediating and some are not.

There is still another view of the principle of the syllogism, which has been held by various writers. It is that it is sufficiently contained in the definition of the proposition—that in saying *Whatever is a is b*, it has already been said that anything that can be shown to be *a* is *b*. Thus the doctrine of the syllogism, under the aspect of rules applied to cases, becomes a tautology; it is simply—A general rule can be applied to any special case that can be shown to fall under it. Mill’s

objection to the syllogism would here amount to saying that there can be no fresh application of a general rule to special cases; for until *after* you have tested it in all its special cases, you are wrong to believe that the rule is really general.

From the time of Sextus Empiricus, it has been maintained by different writers that the syllogism is of little value, that is, leads to no advance in thought, because the conclusion is already contained in the premises. It is true in a sense that there is no gain in material knowledge in the syllogism, but the gain through convenience of manipulation is great. Thus if the axioms, postulates, and definitions of geometry, accurately and fully stated, were handed over to a master of symbolic logic, he could deduce from them, with infallible certainty, the latest proposition of Euclid without stopping to state any of the intermediate propositions; but ordinary reasoners find it vastly more convenient to proceed from step to step, and in fact ordinary human powers, unaided by a mechanical device, do not suffice for any different procedure. What the formal reasoner as such actually does is to sit at his desk, and taking into his consciousness statements of fact brought to him from South Africa and China, from the metaphysical assumptions of the speculative philosopher and from the laboratory work of the experimental psychologist, to piece them together, so far as they have anything in common, and to get out of them things not known *before* they fell together. His intellectual work consists (1) in the search for middle terms, and (2) in the reduction of the propositions containing them to forms in which he is capable of seeing what relations implicitly contained in them he can make explicit, and (3) in stating those conclusions in single sentences. For example, the syllogism

No priests are martyrs;
(v) All but priests are saints;
∴ All martyrs are saints,

cannot be seen intuitionally by every one to be either valid or invalid. (To get the real force of the syllogistic formula, it is much better to practise on propositions which are not true.)

Another objection that has been brought against the syllogism is that the conclusion is *not* contained in the premises, that until the conclusion has been separately tested, it is not safe to say that the major premise is universally true. Bain has very justly said that the contribution made to logic by Mill in connec-

tion with this question is revolutionary; it is, however, properly speaking, a contribution to the theory of knowledge rather than to the theory of the syllogism in itself. His thesis is not so much that 'real reasoning is from particulars to particulars,' as it is that 'all knowledge is in the last resort empirical.' Aristotle himself, according to H. Maier (*Die Syllogistik des Aristoteles*, 1900), was not ready to admit the validity of the syllogistic form as such, in those cases in which the premises are insecure. Our vast structure of knowledge is composed of elements of various degrees of certainty. One piece or another, from time to time, suffers shipwreck; but many pieces have had their validity so thoroughly tested that *relatively* they are inextinguishable. The objection is perfectly well founded in instances where the general rule is got as a direct abstraction from the special cases, and also in the cases where, for any other reason, our grounds for believing it are relatively uncertain; but under all such circumstances we are perfectly aware of what is the real value of the syllogism—that it is in such cases this very function (the testing of the major premise) for the sake of which we perform it. The progress of science consists in great part in guessing at general rules, or in accepting them temporarily as furnished us by more or less uncertain inductions, in applying them to special cases, and then in returning to nature to see if the result of the application holds good. If it does, the rule is in so far confirmed; if it does not, the rule must be revised—for the moment it has become a humble particular, which we hope to elevate again into the rank of a universal by finding some appropriate determinant of the subject, or alternation to the predicate, to connect with it. Thus if $a \leq b$ is found to have exceptions, our next step is to discover the x or the y which will give us $ax \leq b$ or $a \leq b + y$. If, on the other hand, there is a general rule in which we have confidence, and observation has just furnished us with a special case, if the application of rule to case gives a result out of harmony with well-known facts, it is the accuracy of our observation of the special case that we proceed to improve upon. There are always some propositions which are so vastly superior to others in respect of certainty that, unless we are to renounce the task of living altogether, we must feel ourselves authorized to take them as safe premises.

The Modern Treatment of the Syllogism.

Modern logic, which begins with De Morgan and Boole, has for one of its principal characteristics the unrestricted admission of negative terms; the older logicians were chary of introducing them as predicates even. They regarded such a proposition as *Some a is not b* as belonging to a separate category from the universal and the particular proposition, and gave it a distinctive name—the 'infinite or limitative proposition.' But this is unnecessary; it is perfectly safe to treat negative terms like any other terms. And it is only this aversion to dealing with negatives that has caused the logicians to consider that

No a is b ;
No c is \bar{b} ;
 \therefore No a is c ,

is not a syllogism at all. The infelicity of this has been pointed out, among others, by Bradley. It is not a syllogism in the restricted traditional sense of the word, but it is an argument so exactly like it that the difference is entirely inessential; it is merely necessary to let 'common term' include 'common term though of different quality,' for the common definition of syllogism to cover cases like this. The ordinary rules for the validity of syllogistic reasoning are applicable only if the propositions are stated in some one of the four traditional forms. When the eight propositions of the Complete Scheme are taken account of, the restrictions as to negatives being done away with (see PROPOSITION), the number of fruitful pairs of premises is vastly increased. The argument, e. g.,

Everything is either a or c ;
(p) Everything is either b or \bar{c} ;
 \therefore Everything is either a or b ,

would seem strange to the strict Aristotelian, but with the enlarged meaning of common term it falls strictly within the definition of syllogism. And as frequently happens in such a case, the whole is found to be, as regards difficulty, much less than the part; rules for validity, as will appear immediately, are far more simple than with the ordinary propositional scheme.

Two premises and a conclusion taken together constitute a syllogism; the three following propositions taken together—

'None who are discontented are happy,'
'But some reformers are happy'
and no reformers are contented,'

form an argument,—not, it is true, an argument in which there is a sequence, but an argument in which there is a rebuttal. (It is, without doubt, the form in which, in primitive

times, argument first arose; propositions are accepted 'unthinkingly' until after they have been uttered, and have aroused—the regular effect of listening to speech—the instinct of rejection on the part of the hearer.) In this argument the implication contained in the word *but* is that the statements made cannot be all three true together; if the last two are true, the first is not so; if the first and either of the others are true, the remaining one is not true. In other words, the three propositions taken together constitute an inconsistency, or an incompatibility, or, as it may perhaps be called, to distinguish it from the syllogism, an antilogism. Expressed in letters for terms, it affirms that no *a* is *b*, no *c* is non-*b*, and some *a* is *c* cannot be all three true at once; if any two of them are known to be true (it matters not which two) the remaining one is known to be false—that is as much as to say that its contradictory is known to be true, and to be, therefore, the conclusion of a valid syllogism of which the other two are the premises.

If we write for the moment $(ab)_o$ for *No a is b* and $(ac)_u$ for *Some a is c* (*u* is chosen as standing for a part of the universe), we may put this:—

$$(ab)_o (cb)_o (ac)_u \leq 0,$$

which is read *That no a is b, no c is non-b, and some a is c is impossible*. The simple test for the validity of this form of argument is this: (1) *There are three propositions, two universal and one particular, each two with one term in common.* (2) *The term common to two like propositions must appear with unlike signs; the term common to two unlike propositions must appear with like signs.* The dictum involved is simply the principle of Excluded Middle: *ac* is not *b* (for no *a* is *b*), and it is not non-*b* (for no *c* is non-*b*), and hence it cannot exist at all.

The simple device, therefore, for testing the validity of any of the thousands of syllogisms such as (v) and (p) , which may present themselves to the actual reasoner, in addition to the ordinary syllogisms of the logics ($16 \times 16 \times 16 \times 2$, or 8,192 in all), is to turn every universal proposition into the form *No a is b*, every particular into the form *Some a is b*, to deny the conclusion, and then to apply the rule just given. The source of the simplicity of this rule is that symmetrical copulas are used throughout, and that therefore it no longer makes any difference whether a term stands in the subject or in the predicate.

A consideration of these more general forms covers, in simple terms to start with, all the

so-called hypothetical and alternative syllogisms, and many more, of course, than are usually treated in the textbooks. The existential syllogism is represented, in terms, by

All *a* is *b*;
a is existent;
 \therefore *b* is existent,

which is the exact parallel to

Always, if *a* is *b*, *c* is *d*;

That *a* is *b* occurs (here and now);

\therefore That *c* is *d* occurs (here and now).

These last two forms differ from the ordinary syllogism merely in the fact that one of the SPECIAL TERMS of logic (q.v.) occurs as a predicate. They may be named *existential syllogisms*. Modal propositions are most simply treated by making the modal word a predicate, instead of attaching it to the copula—that is, by transforming *a is possibly b* to *That a is b is possible*. We have merely to remember, then, that the negative of *necessary* is *possibly not*, and that the negative of *possible* is *necessarily not*. (C.L.F.)

(2) The syllogistic inference may be analysed into several distinct steps, each of which shall consist either in inserting or in omitting something. It does not evidently follow that such a method must afford a simpler representation of necessary inference than to take the inference of the *modus ponens* as elementary. But in point of fact it does so. The passage from premise to conclusion may be regarded as a permissible transformation, and best, of a transformation of the nature of an insertion; that is to say, the conclusion is superadded to the premises; since the premises remain true.

Aristotle's verb $\sigma\upsilon\mu\beta\alpha\iota\upsilon\epsilon\iota$ in the definition of the syllogism takes this view. The relation between the protasis and apodosis of a hypothetical proposition differs formally from the relation between a premise and conclusion in no essential respect, except that the protasis is not positively asserted. To regard the fact *C* as necessarily following from the facts *A* is to hold that whenever facts analogous to *A* are true, a conclusion related to them as *C* is to *A* will always be true. In the proposition, 'If *A* is true, *C* is true,' we may have regard only to the actual state of things; in any case the proposition is equivalent to 'Either *A* is not true, or *C* is true.' But more usually we refer to a range of possibilities, and mean that whenever any fact analogous to *A* is true, that which is related to it as *C* is to *A* is true. The same relation subsists between the subject and

predicate of a universal proposition: to say that 'All men are mortal' is to say that, taking any object X whatsoever, if X is a man, X is mortal. This agrees with the definition of universal predication given by Aristotle, and commonly known as the *dictum de omni*. It will be remarked that this definition does not make a universal proposition to assert the existence of its subject.

Now, since in any possible system of logical representation illative transformation must be performed and be recognized as permissible, it follows that any representation of a universal proposition which treats any other relation than that of the conclusion (with the premises) to the premises alone as the principal relation expressed by the proposition, leaves the logical analysis incomplete.

Three figures (see FIGURE, syllogistic) of syllogism were recognized by Aristotle, in the first of which the middle is subject of one premise (the *major* premise) and predicate of the other (the *minor* premise); in the second the middle is the predicate of both premises; while in the third the middle is subject of both premises. Aristotle recognizes but four moods (see MOOD, in logic) of syllogism in the first figure. Some early Peripatetic, Theophrastus it is said, added five indirect moods: *Baralipon*, *Celantes*, *Dabitis*, *Fapesmo*, *Frisosomorum*. It is rumoured that Galen first constituted a fourth figure by transposing the premises of these. About the 16th century this figure began to be commonly admitted, and is now almost universally so. With this, the five moods have somewhat unnecessarily changed their names. Those now most usual are *Bramantip*, *Camenes*, *Dinaris*, *Fesapo*, *Fresison*.

The logic of RELATIVES (q. v.; see also SYMBOLIC LOGIC) throws great light on syllogism. It shows that the copulated premises are, as expressed in Peirce's algebra of dual relatives, in one of the three forms,

$$(x + \bar{y})(\bar{y} + z) \quad (x + \bar{y})\bar{y}z \quad (x\bar{y})\bar{y}z$$

These give respectively

$$x + z \quad xz \quad x \text{ T } z$$

The last is a so-called spurious conclusion, but such syllogisms are unscientifically excluded from consideration in almost all treatises. There remain, therefore, but two kinds of syllogism, the *universal* and the *particular*. Beginning with *Barbara*, it can be mathematically proved that every possible necessary inference from two premises, both having the same form as the conclusion, must depend upon a relation of *inclusion* (see Schröder, *Alg. u.*

Log. d. Relative, 337 ff., where the 'solution' given of transitivity is the most accurate possible definition of *inclusion*, in that general sense in which a thing need not necessarily include itself). Thus,

The S 's are included among the M 's;

The M 's are included among the P 's;

\therefore The S 's are included among the P 's.

So, for example, the pseudo-syllogism $S < M$, $M < P$, $\therefore S < P$, depends partly on the fact that $S < P$ implies that the units required to measure S are included among those required to measure P , and partly on the fact that $S < P$ implies that the units required to measure P are not included among those required to measure S . Putting, therefore, s, p , and m for the units required to measure S, P , and M , we have, on the one hand,

The s 's are included among the m 's;

The m 's are included among the p 's;

\therefore The s 's are included among the p 's;

and, on the other hand,

The s 's are not included among the m 's;

The p 's are not included among the m 's;

\therefore The p 's are not included among the s 's.

If, in order to study the differences between the different moods of syllogism, we suppose that in the universal proposition S and P are modified by relatives, these must be the same for both, in order that *Barbara* should be valid. Calling this common relative h , the form of the universal affirmative, A , can only be one of the two following:

Any h of an s is an h of a p ;

Any h of every s is an h of every p .

These differ merely as being the converse of one another. For putting k for non- h , the latter is equivalent to

Any k of a p is a k of an s .

We may, therefore, assume the first of the two forms as the form of A . Then the validity of *Celarent* requires only that the universal negative E shall have for its subject, 'Any h of an s ' or 'Something not an h of an s .' The validity of *Darii* requires only that the predicate of the particular affirmative, I , shall be 'is an h of a p .' The validity of *Ferio* requires that the subject of the particular negative, O , should agree with that of I (in a sense not easy to explain without special notation), while its predicate should be the same as that of E , and further, that if either I or E expresses existence, so should O . The validity of *Baroko* and the moods of the second figure, generally, requires that the predicate of O (and of E) should be 'is not an h of a p .' The validity of *Bokardo* requires that the subject of O (and

of I) should be either 'Some *h* of an *s*' or else 'Anything but an *h* of an *s*.' The result is that there are three systems of propositions which give all the traditional moods, except *Darapti*, *Felapton*, *Baralipon*, and *Fapesmo*, which are invalid if universal propositions are understood to be the exact denials of particular propositions. These three systems are:—

FIRST SYSTEM.

- A. Any *h* of an *S* is an *h* of a *P*;
- E. Any *h* of an *S* is not an *h* of a *P*;
- I. Some *h* of an *S* is an *h* of a *P*;
- O. Some *h* of an *S* is not an *h* of a *P*.

SECOND SYSTEM.

- A. Any *h* of an *S* is an *h* of a *P*;
- E. Something not an *h* of an *S* is not an *h* of a *P*;
- I. Whatever is not an *h* of an *S* is an *h* of a *P*;
- O. Some *h* of an *S* is not an *h* of a *P*.

THIRD SYSTEM.

- A. Any *h* of an *S* is an *h* of a *P*;
- E. Any *h* of an *S* is not an *h* of a *P*;
- I. Whatever is not an *h* of an *S* is an *h* of a *P*;
- O. Whatever is not an *h* of an *S* is not an *h* of a *P*.

The O of the third system might have been taken as A, and the same forms would have been reproduced in the same way with changed *h*. In the ordinary syllogistic the first system is used, and *h* is 'identical with.' With a limited universe of marks, *h* will be a 'character of.'

It will be observed that *Celarent* and *Darii* introduce each an additional principle in slight modification of *Barbara*, and *Ferio* reunites those principles. The *second* and *third* figures introduce marked additional principles, which the so-called fourth figure, i.e. the Theophrastean syllogism, reunites. In the second figure there is a perceptible difference between the mode of inference of *Camestres* and *Baroko* on the one hand, *Cesare* and *Festino* on the other; although in *reasoning* itself it is morally impossible to distinguish *Camestres* from *Cesare*. Parallel remarks apply to the third figure. Of the Theophrastean moods, *Frisesomorum* alone is peculiar, *Celantes* and *Dabitis* depending merely on the principles of the second and third figures respectively.

The fact that the second and third figures involve peculiar principles is shown by the fact that the modes of reduction of any mood of each involve some peculiar immediate inference.

Thus, the reduction of the second figure involves the conversion of E. Now this conversion can be stated in syllogistic form; but it will be a syllogism in *Cesare*, which is the typical mood of the second figure, thus:—

No *M* is *N*;

Any *N* is *N*;

∴ No *N* is *M*.

So the third figure involves the conversion of I, and when this is put into syllogistic form, the syllogism is in *Datisi*, the typical mood of the third figure, thus:—

Any *N* is *N*;

Some *N* is *M*;

∴ Some *M* is *N*.

It may be said that the convertibility of I depends upon the equiparance of the relation which I expresses. But even in that case, it must be noted that there is a certain difference between the *individual* and *definite* convertibility commonly understood by equiparance and the *indefinite* conversion, properly understood, of I, which is alone required in ordinary syllogistic. This will appear below.

The second and third figures can be reduced to the first apagogically, but the principles of the reduction are different. That of the second figure is that if the *negative* (not the denial) of the result of a hypothetical assumption under a known rule is found to be true, then the negative of the subsumption is true. Thus, referring to the usual syllogism, 'All men are mortal; all patriarchs are men; hence, all patriarchs are mortal'; if the rule is correct, get all patriarchs are immortal, it follows that all patriarchs are non-men. The statement of this principle is simply a form of the conversion of E. So the third figure may be apagogically reduced by the principle that if, a subsumption under a hypothetical rule being admitted, a partial result is found true, the partial truth of the rule follows. Thus, admitting that all patriarchs are men, if it be found that some patriarchs are mortal, it follows that at least some men are mortal. The second figure can always be reduced to the first by the simple conversion of the major premise, this being first made negative, if necessary, by infinitation. Thus,

Any *M* is *P* = Any *M* is not not-*P*;

Any } *S* is not *P*;

Some }

∴ Any } *S* is not *M*,

Some }

is reduced by the conversion of the major to

'No not- P is M .' So the third figure is reduced to the first by the simple conversion of the minor premise. But there is here a difficulty, owing to our not having in our ordinary languages a term to express the reversal of the quantity of a proposition; that is to say, a single operation which shall change Any to Some, and Some to Any.

The difference between a particular and a universal proposition is that, in the former, the selection of the individual of which the predicate is asserted is transferred from the hearer to a person competent and friendly to the proposition. Let this transfer be repeated, and the choice goes back to the first party. Using 'some' in the sense of prescribing such transfer, 'Some-some- S is P ' = Any S is P . In that way *Disamis* and *Bokardo* are reduced as follows. The moods are:

Some S $\left\{ \begin{array}{l} \text{is} \\ \text{is not} \end{array} \right\} P$;
 Any S is M = Some-some- S is M ;
 \therefore Some M $\left\{ \begin{array}{l} \text{is} \\ \text{is not} \end{array} \right\} P$.

Converting 'Some-some- S is M ' to 'Some M is Some- S ,' we have the syllogism of the first figure—

Any Some- S $\left\{ \begin{array}{l} \text{is} \\ \text{is not} \end{array} \right\} P$;
 Some M is Some- S ;
 \therefore Some M $\left\{ \begin{array}{l} \text{is} \\ \text{is not} \end{array} \right\} P$.

Any syllogism of the second or third figure can also be reduced by transposing the premises, and converting the two propositions not converted in the method just described. But still the same kind of conversion continues to be required in the case of each figure, thus showing that the conversions of E and I are logically allied to the second and third figures respectively. *Camestres* and *Disamis* are the easiest so to reduce; *Festino* and *Ferison* the most difficult.

Festino.

Some S is P = No Some- S is not- P ;
 No M is P = Any M is not- P ;
 \therefore Some S is not M = No Some- S is M .

The conversion of E gives from the first premise 'No not- P is Some- S .' This with the second premise gives 'No M is Some- S .' Thence another conversion of E gives 'No Some- S is M ,' which is the conclusion.

Ferison.

Some S is M = Any Some- S is M ;
 No S is P = Some-some- S is not- P ;
 \therefore Some M is not P = Some M is not- P .

The conversion of I gives from the second premise 'Some not- P is Some- S .' This with the first premise gives 'Some not- P is M ,' which by another conversion of I gives 'Some M is not- P ,' the conclusion.

The conversion of E depends on the fact that otherness is an equiparance. If everybody loves everybody who loves him, it follows that if every man loves every woman, then every woman loves every man; and on the corresponding principle, if every S is other than every P , then every P is other than every S . The conversion of I, on the other hand, is justified by the fact that the propositional quantities of breadth and depth are inseparable. 'Some S is P ' = There is an embodiment of S conforming to the idea of P .

Now observe that we do not necessarily infer that that *same* P is S , but only that there is somewhere a P that is S . All that is needed for this inference is that whenever there is an embodiment of an idea conforming to a second idea, there is also an embodiment of the latter idea conforming to the idea first embodied. It is the principle that there cannot be a cork that fits a bottle unless there be a bottle that is fitted by a cork.

When we pass to probability the figures of syllogism become of an idea highly important. Thus, take the following reasoning, the nature of which we shall presently examine:

The probability of throwing doublets with a pair of dice is $\frac{1}{6}$;

Different throws of pairs of dice are independent;

\therefore The probability of throwing precisely two doublets in six throws is just half that of throwing precisely one doublet in six throws.

In order to analyse this reasoning, it is necessary to note what the premises and conclusion mean. The precise meaning of the first premise is that we should square our actions on each single occasion to the fact that, taking throws of the dice as they occur in the course of experience, the ratio of the number of throws of doublets hitherto to the total number of throws hitherto would, if the course of experience were endless, become, after a time, permanently remote from every other ratio than 1 : 6, but would never become so from this ratio. The meaning of the second premise is that this is so not only for all the throws, but also for every endless portion of that totality of throws whose selection is determined by the ordinal relation of the throws composing it to previous throws of any given

kind; so that, where such principle of selection allows, the throws are taken as they occur in the course of experience in endless succession.

The necessary conclusion is that we should square our action on any occasion to the principle that taking an endless succession and entirely different sets of six throws, just as they occur in the course of experience, the ratio of the number of sets containing two doublets to the number of sets containing one doublet will at length permanently depart from every other ratio than $1:2$, but will not so depart from this ratio.

This inference is necessary; yet it is merely probable in this sense, that we cannot be sure that the number of sets of six throws containing just one doublet would be twice the number containing two doublets in a hundred trials, or in a million, or in any other fixed number. But what is certain is that any other ratio would eventually prove decidedly wrong, while $1:2$ would not. This is a probable syllogism of the first figure, since it recognizes a case as coming under a general rule, the result of which it accepts as valid in that case. Of course the reader will not fail to observe that the sense in which the reasoning is said to be a syllogism is strictly defined. It is not meant that the above is a simple syllogism.

But if it were not known exactly how often with a given set of dice doublets would be thrown, since they may be similarly or dissimilarly loaded, and if we simply threw the dice and counted the whole number of throws and the number of throws of doublets, and if, finding that in twelve hundred throws there were about two hundred doublets, we were thence to conclude that in the long run about one-sixth of the throws would be doublets, this would be reasoning in the third figure. This would be in no sense necessary, except that if the experimentation were continued endlessly, it must approximate to the true ratio at last. This form of reasoning differs from the probable syllogism of the first figure, in that there the precise value of the long-run ratio was stated in advance; while here the concluded ratio is subject to modification as experience is amplified.

It is inference in the third figure, since if the rule were that any ratio far from one-sixth would be satisfactory in the long run, the same ratio would probably be tolerably satisfactory in twelve hundred throws. Now, no ratio far from one-sixth is satisfactory for

this set of twelve hundred throws. Hence, the rule is probably false. Now, the inference that a general rule is false because the result to which it would lead in a special case is not true is syllogism of the third figure. Although this mode of inference is not necessary, it is necessary that the method should ultimately yield an approximately correct conclusion.

A probable syllogism which appears, in consequence of a want of sharp insistence upon what is really the subject and what the predicate of propositions, to be in the second figure may be essentially of the same nature as a probable syllogism in the third figure; but it seems to be impossible that it should really be so, since there can be no strict objective probabilities of the kind required. If, for instance, we knew that in a considerable series of sets of six throws, one doublet precisely had occurred in a set twice as often as two doublets precisely, and we were thence to conclude that the two dice were probably normal, because, although other constitutions of dice might produce the same result, yet they are very unusual constitutions, we have here a probability of quite another kind; and instead of its being certain, as in the third figure, that the method of inference would in the long run lead to an indefinite approximation to the truth, it is here quite possible that the concluded constitution of the dice will always be entirely different from the true one. The three figures are therefore quite distinct; and we see that probability lends an importance to the three figures which modern logicians have not been willing to accord to them.

Aristotle pays no attention to hypothetical syllogisms; but it is said that Theophrastus studied them. We find them treated in considerable detail by Boethius. During the middle ages, purely formal syllogistic made no progress worth mention. About the middle of the 19th century some steps were taken. Sir W. Hamilton proposed a syllogistic system of no merit (see *An Essay on the new Analytic of Logical Forms*, by T. S. Baynes, Edinburgh, 1850) based on the following system of propositional forms, called the system of the thoroughgoing quantification of the predicate.

All A is all B , meaning that the whole collection of A 's is identical with the whole collection of B 's.

All A is some B , meaning that the whole collection of A 's is identical with part of the collection of B 's.

Some A is all B , meaning that a part of the collection of A 's is identical with the whole collection of B 's.

Some A is some B , meaning that a part of the collection of A 's is identical with a part of the collection of B 's.

Any A is not any B , meaning that the whole collection of A 's is excluded from the whole collection of B 's.

Some A is not any B , meaning that a part of the collection of A 's is excluded from the whole collection of B 's.

Any A is not some B , meaning that the whole collection of A 's is excluded from a part of the collection of B 's.

Some A is not some B , meaning that a part of the collection of A 's is excluded from a part of the collection of B 's.

There is also a pretence at a second series of meanings in depth, never clearly explained. Such a system is glaringly faulty; but it had some vogue in its day. There were also some other somewhat similar systems by Archbishop Thomson, Spalding, &c.

De Morgan constructed various systems of syllogistic of much greater merit, although, after all, they only complicate the subject to no purpose. His principal system, in which he postulates that no term is without breadth or is coextensive with the universe, is based on the following propositional forms :

X))Y. All X's are some Y's, i. e. Any X is a Y.

X). (Y. All X's are not (all) Y's, i.e. Any X is non-Y.

$X(\cdot)Y$. Everything is either some X or some Y (or both), i.e. Any non- X is Y .

$X \ll Y$. Some X 's are all Y 's, i.e. Any non- X is non- Y .

$X(\cdot(Y$. Some X 's are not (all) Y 's, i. e.
Some X is non- Y .

$X()$ Y. Some X 's are some Y 's, i.e. Some X is Y .

X)(Y . Some things are not either (all) X 's or (all) Y 's, i. e. Some non- X is non- Y .

X).) Y . All X 's are not some Y , i.e.
Some non- X is non- Y .

These forms arose, as one might guess, from the application of *not* to the subjects of the old four ; so that it might be called the system of the thoroughgoing qualification of the subject. Whether or not this qualification of the subject can be said to be involved

in the structure of any syllogism is the question upon the decision of which that of the acceptance of De Morgan's system must depend.

Under these conditions (figure of course disappearing) De Morgan gets eight universal syllogisms,

$$\begin{aligned} & \left. \begin{array}{l} \text{))))} \\ \text{)))))} \end{array} \right\} \cdot ((\cdot)) \quad (((\cdot) \quad ((((\cdot)) \cdot (\quad)) \cdot (\quad) \cdot (((\\ & \quad \cdot ((\cdot)); \end{aligned}$$

eight *major-particular* syllogisms,

$$(((\cdot)) \cdot ((\cdot))) \cdot (((\cdot) \cdot (\cdot)) \cdot ((\cdot)))$$

and eight *minor-particular* syllogisms

$$\begin{aligned} & ((\cdot)) \quad) \cdot)) \quad)((\cdot) \quad)(((\quad) \cdot)) \cdot (\quad (\cdot) \cdot (\quad (\cdot(((\\ & \quad (\cdot((\cdot), \end{aligned}$$

De Morgan also takes account of complex premises. Moreover, he developed the syllogistic of relative terms, and especially the highly important *syllogism of transposed quantity*; and he, Boole, and others studied numerically definite syllogisms.

The following technical phrases may be defined:

Arithmetical syllogism. Blundevile, in his *Arte of Logicke* (1599), in illustration of his position that 'God hath prescribed certaine bounds of necessitie . . . which bounds are Syllogismes rightly made,' instances this question: 'If one pound of waxe be worth a groat, what is tenne pound of waxe worth? Marry tenne groates, which is prooved by a Syllogisme in this manner: Every pound of waxe is worth a groat; but here is ten pound of waxe: *Ergo*, they are worth ten groats: and like as in these kinds of Sillogismes Arithmetically, the proportion which is to bee judged by mans naturall knowledge, doth shew the Consequent to bee infallible, even so the Consequents in other Syllogismes are shewed to be infallible, by such demonstrations as are not farre fetched, or doubtfull, but are manifest, plaine and evident.'

Categorical syllogism: a syllogism composed of categorical propositions.

Common syllogism: a syllogism whose middle is a general term.

Composite syllogism: a syllogism having more than two premises.

Compound syllogism : a hypothetical syllogism, that is, a syllogism containing a disjunctive (or conditional) or copulative premise.

Conditional syllogism: a syllogism containing a conditional premise, especially the *Modus Ponens* and *Modus Tollens*, although some logicians refuse to these arguments the name of syllogism.

Conjunctive syllogism: according to Hamilton (*Lect. on Logic*, Appendix VIII), a *conditional syllogism* (above).

Contentious syllogism: a fallacy, whose author seeks only victory in argument.

Copulative syllogism: a syllogism with a copulative conclusion.

Decurtate syllogism: a syllogism with one of the premises unexpressed (*Cent. Dict.*).

Defective syllogism: a syllogism in the statement of which one of the premises is omitted.

Demonstrative syllogism: a syllogism which generates science.

Dialectic syllogism: a syllogism which generates opinion, being made of probable and credible propositions. The phrase is as old as Aristotle; but the use to which syllogism is put does not alter its nature. It is the argumentation or reasoning, not the logical form, which is dialectical.

Didascatic syllogism: same as *Demonstrative syllogism* (above).

Dilemmatic syllogism: a syllogism having for its minor premise a dilemmatic proposition (*Cent. Dict.*). See DILEMMA.

Direct syllogism (συλλογισμὸς δεικτικός): a syllogism proceeding from a *rule*, and the subsumption of a *case* under that rule, to the *result* of the rule in that case. One of the four moods, *Barbara*, *Celarent*, *Darii*, *Ferio*.

Disjunctive syllogism: a syllogism whose cogency depends upon the relation between the members of a disjunctive premise.

Expository syllogism: a syllogism whose middle is an individual term.

Figured syllogism: a syllogism so stated that it is in a definite figure.

Hypothetical syllogism: a syllogism either conditional (or disjunctive) or copulative. Often used for a syllogism conditional but not disjunctive, although there is no material difference between a conditional and a disjunctive proposition. A copulative proposition is the precise denial of a conditional or disjunctive proposition; and every conditional or disjunctive syllogism will by apagogical transformation give a copulative syllogism. But many logicians refuse to consider copulative syllogisms to be syllogisms on the ground that the conclusion contains nothing not stated in the premises taken together; just as the same logicians exclude other arguments from the class of syllogisms because their conclusions contain matter not contained in the premises taken together.

Imperfect syllogism: a syllogism of which one premise remains unstated.

Indirect syllogism: a syllogism which needs to be proved to be valid by reduction to direct syllogism.

Modal syllogism: a syllogism containing modal propositions.

Perfect syllogism: a syllogism of which no part of the leading principle can be stated as a premise and so eliminated from the leading principle; since if this is attempted it is still needed as leading principle.

Proper syllogism: the Ramist name for an *Expository syllogism*.

Proportional syllogism: a species of relative syllogism depending on proportions. The following is a stock example:

Ut se habent duo ad quattuor, ita se habent tria ad sex:

Sed duo se habent ad quattuor, ut dimidium ad totum:

Ergo, tria se habent ad sex, ut dimidium ad totum.

Pure syllogism: a syllogism composed of propositions *de inesse*.

Relative syllogism: a syllogism involving relative terms. Such syllogisms have been recognized as proper subjects of logic by all logicians beginning with Aristotle.

Simple syllogism: a syllogism not capable of dissection into two or more syllogisms. But the indirect syllogisms which have always been recognized as composed of direct syllogisms and immediate inferences are always classed as simple syllogisms, and that, although Aristotle and others prove those immediate inferences syllogistically.

Singular syllogism: see *Expository syllogism*.

Sophistic syllogism: a syllogism intended to deceive, or which it is pretended is intended to deceive. See SOPHISM.

Tentative syllogism (συλλογισμὸς πειραστικός): seems to be much the same as a *Dialectic syllogism* (above).

Valid syllogism: a syllogism whose premises assert facts whose being is partly composed of the being of the fact asserted in the conclusion.

Syllogism of transposed quantity: a syllogism in which the whole quantity of one concluding term, or its contrary, is applied in a premise to the other concluding term, or its contrary, by means of a relation of one-to-*N* correspondence. As in the following: Some *X*'s are not *Y*'s; for every *X* there is a *Y* which is *Z*; hence, some *Z*'s are not *X*'s. (C.S.P.)

Syllogistic (argumentation; also used as a noun). SYLLOGISM (q. v.).

Symbol [Gr. σύμβολον, a conventional sign, from σύν + βάλλειν, to throw]: Ger. *Symbol*; Fr. *symbole*; Ital. *simbolo*. (1) A SIGN (q. v.) which is constituted a sign merely or mainly by the fact that it is used and understood as such, whether the habit is natural or conventional, and without regard to the motives which originally governed its selection.

Σύμβολον is used in this sense by Aristotle several times in the *Peri hermeneias*, in the *Sophistici Elenchi*, and elsewhere.

(2) An algebraic character. (G.S.P.)

Symbol (and **Symbolic**) [Gr. σύν + βάλλειν, to put together, compare]: Ger. (*symbolisch*); Fr. (*symbolique*); Ital. (*simbolica*). (1) An object which stands for some other object or idea; the former is said to be 'symbolic' of the latter. Cf. SIGN, and SIGN-MAKING FUNCTION.

(2) In aesthetics, an object which, apart from its own immediate and proper significance, suggests also another, especially a more ideal content which it cannot perfectly embody.

The symbol may be either natural: as light is a symbol of truth; or traditional and conventional: as the cross is a symbol of sacrifice.

The conception of art as symbolic goes back at least to Plotinus, but the term seems to have come into general aesthetic currency through Goethe and Schlegel—the latter declaring it to be (in sense 1, above) the essence of all art. Hegel made the symbolic in sense (2) the principle of oriental as compared with Greek art. Vischer laid special stress on the symbolic (significant) character of art, as against the Formalists. Recently, the psychology of symbolization has received special treatment. Fechner explained it as association. Others have considered it as an investiture of the object with the observer's own idea and feeling in a more intimate manner than is implied by the term association, and have sought for terms expressing this, as 'mitfühlen,' feeling with (Lotze), 'einfühlen,' feeling into (R. Vischer, Fr. Vischer), a lending or animating (Leihen, Beseelung; Fr. Vischer), fusion (Verschmelzung; Volkelt). According to Lotze we live over again in the object the motion to produce it, &c. Groos (*Play of Man*, Eng. trans., 31) makes eye-movements and other 'inner imitations' 'symbolic' of the real movements of imitation. See SYMPATHY (aesthetic).

Literature (to 2): HEGEL, *Aesthetik*, ii. Th.,

i. Abth.; STERN, *Einführung u. Association in d. neu. Aesth.* (1898); FECHNER, *Vorschule d. Aesth.*, ii; LOTZE, *Gesch. d. Aesth.*, 74 ff.; FR. VISCHER, *Aesthetik*; Krit. Gänge, v, vi; and *Das Symbol*, Altes u. Neues (1889); R. VISCHER, *Über d. optische Formgefühl* (1873); VOLKELT, *Der Symbolbegriff in d. neuesten Aesth.* (1876); LIPPS, *Raumästhetik u. geometrisch-optische Täuschungen* (1897); VOLKELT, *Zeitsch. f. Philos.*, cxiii. 161-79; STERN, *ibid.*, cxv. 193-203; KÜLPE, *Zeitsch. f. wiss. Philos.*, xxiii. 145-83; TURNARKIN, *Arch. f. Gesch. d. Philos.*, xii. 257-89; FERRERO, *I simboli* (1892). Cf. also FORM, BALANCE, SYMMETRY. (J.H.T.)

Symbolic Function: no foreign equivalents in use. The function whereby a mental result primarily referring to one set of objects is transferred to another set of objects; the first set is said to be symbolic of the second.

SYMBOL (q. v.) is frequently used in a very wide sense as equivalent to any kind of sign. But it seems desirable to limit its application in psychology to cases in which the sign is provisionally substituted for the thing symbolized. Words are not substitute signs in this sense; they are means by which we attend to what is signified, not themselves objects of attention. Cf. SIGN-MAKING FUNCTION, and SIGN (for a more special meaning of symbol). (G.F.S.)

Symbolic Logic or Algebra of Logic: Ger. *Algebra der Logik*; Fr. *logique symbolique ou algorithmique, algèbre de la logique*; Ital. *logica simbolica*. Symbolic logic is that form of logic in which the combinations and relations of terms and of propositions are represented by symbols, in such a way that the rules of a calculus may be substituted for actively conscious reasoning.

An algebra of logic enables us to disengage from any subject-matter the formal element which gives its necessary (apodictic) force to reasoning; it is therefore nothing but an exact logic, that is to say, the complete realization of the purpose of formal logic (cf. PROPOSITION). The ordinary formal logic has, from the earliest times, substituted symbols (viz. the letters of the alphabet) for significant terms, and has thus added much to the facility with which the validity of arguments can be tested; symbolic logic goes a step further, and adds symbols to stand for combinations of terms, or functions of terms, and statements of relations between terms. The aid which is thus given to logic, not only in the carrying out of complicated trains of

reasoning, but also in the exact analysis of the various steps involved, is very great.

Several systems of symbolic logic have been proposed within the last half-century (see literature). We shall here describe only one—that of Boole, as reformed and developed by Schröder, Peirce, and others. This system is not based exclusively upon the consideration of the extension (application) of terms and of propositions, but covers all relations of intension (SIGNIFICATION, q. v.) as well. It is, however, more convenient, when formulae are to be expressed in words, to use the language of one or the other of these two parallel interpretations exclusively; that of the application-interpretation will be used in what follows.

Throughout symbolic logic there is an exact analogy between terms and propositions, so that the same theorems (or formulae) apply to both; it is not a case of two parallel systems (a calculus of concepts and a calculus of propositions), but of a single system susceptible of a double interpretation. In what follows, the letters of the alphabet stand for either concepts or propositions¹.

The algebra of logic rests upon two *relations*—that of inclusion (or subsumption, or sufficient condition) and that of equality, of which the first only is fundamental—and upon three operations—aggregation (or logical addition), composition (or logical multiplication, as it has been unfortunately named, upon a false analogy), and negation. Of the three operations, negation together with either of the other two would suffice for the algebra (though facility of expression is greatly increased by admitting all three of them); hence one relation (or form of statement) and one operation, together with negation (applied not only to terms but also to the assumed form of statement and to the assumed operation), are all that are absolutely essential to the building up of the theory.

The relation of inclusion, which is written $a \leq b$, signifies that the class a constitutes a part (or it may be the whole) of the class b , or that the quality-complex a is indicative of the quality-complex b , or that the statement a involves the statement b . Conceptual Interpretation: The a 's are all b 's; Propositional Interpretation: If a is true b is true, or, a entails b . The relation of equality, or identity, which is written $a = b$, signifies, for one thing, that the two classes a and b are identical

(made up out of the same elements). It may be defined as equivalent to the system of two inverse inclusions

$$(a \leq b) (b \leq a);$$

C. I.: All a is b and all b is a ; P. I.: a entails b and b entails a . In the case of propositions, logical equality is called *equivalence*. Multiplication and addition are thus defined in terms of classes: the sum of two classes is the class which contains all the elements of each (without repetition); the product is the class which contains all the elements which are common to both. Formally these operations may be defined as follows:

$$(a \leq c) (b \leq c) = (a + b \leq c);$$

C. I.: If a is c and b is c , what is either a or b is c , and conversely; P. I.: If a implies c and b implies c , whatever implies either a or b implies c , and conversely.

$$(c \leq a) (c \leq b) = (c \leq ab);$$

C. I.: If c is a and c is b , c is a and b , and conversely; P. I.: If c implies a and c implies b , c implies both a and b , and conversely. It will be seen that the signs $+$ and \times (understood in the form ab) correspond to a certain extent to the conjunctions *or* and *and*, but not completely; for instance, $a + b \leq c$ must be read ' a and b are c ,' but by throwing the first member of this inclusion into a subordinate predicate (which can always be done without change of meaning) it may be read ' $\text{What is } a \text{ or } b \text{ is } c$.' The inclusion $ab \leq c$ can be read ' a which is b is c ,' or ' b which is a is c ,' or ' $\text{What is } a \text{ and } b \text{ is } c$.'

It is necessary to define at once two special terms which play an important rôle in symbolic logic, the logical *zero* (\circ) and the logical *everything* (∞ or $\mathbf{1}$). They are defined formally as follows:

$$\circ \leq x, \quad x \leq \mathbf{1},$$

where x stands for any term whatever, or for any proposition whatever. In the conceptual interpretation, $\mathbf{1}$ is *everything* which *exists*, or the universe of discourse, and \circ is *nothing*, or the *non-existent*; in the propositional interpretation, $\mathbf{1}$ is the aggregate of those states of things which *occur*, or are *true*, and \circ is the *false*, or the *non-occurrent*. The special terms may equally well be defined as follows:

$$x + \circ \leq x, \quad x \leq x \times \mathbf{1};$$

we should then say that \circ is that term which, when added to any term, makes it no greater than it was before, and that $\mathbf{1}$ is that term which, when compounded with any term, makes it no less than it was before. From either of these pairs of definitions the other

¹ Abbreviations: C. I. = conceptual interpretation; P. I. = propositional interpretation.

pair follows at once; the following formulae are also evident:

$$\begin{aligned} 0 &\leq 0, & 0 &\leq 1, & 1 &\leq 1, \\ (x \leq 0) &= (x = 0), & (1 \leq x) &= (1 = x), \\ x + 0 &= x, & x \times 1 &= x. \end{aligned}$$

The third operation of exact logic is negation. It is indicated by a horizontal line placed above the term or the expression to be denied; \bar{a} signifies non- a ; $\bar{a} \leq \bar{b}$ is the denial of All a is b . (In this last case the sign of negation may be equally well placed upon the copula; $a \leq \bar{b}$ means Not all a is b .) Negation may be defined formally by the two following statements: $a\bar{a} \leq 0$, $1 \leq a + \bar{a}$, which translate respectively the principles of 'contradiction' (or mutual exclusion) and of 'excluded middle' (or conjoint exhaustion—see LAWS OF THOUGHT). C.I.: a which is non- a is non-existent, Everything is a or non- a ; P.I.: The statements a and non- a cannot both be true at once, What is possible is that a is true or that non- a is true (i.e. that a is false). It can be proved that the negative as thus defined is unequivocal, i.e. that the term non- a is unique.

The propositions of logic may all be deduced from the definitions and a limited number of principles, or axioms, which are independent and irreducible; among them are the principle of identity: $a \leq a$ (C.I.: All a is a ; P.I.: If a is true a is true), which has for a corollary $a = a$; and the principle of the syllogism:

$$(a \leq b) (b \leq c) \leq (a \leq c)$$

(C.I.: If a is b and if b is c , then a is c ; P.I.: If a implies b and b implies c , then a implies c). The operations of multiplication and addition are subject to the commutative law,

$$a + b = b + a, \quad ab = ba,$$

the associative law,

$$(a + b) + c = a + (b + c), \quad (ab)c = a(bc),$$

and to the special law of tautology,

$$a + a = a, \quad aa = a.$$

The law of absorption,

$$a + ab = a, \quad a(a + b) = a,$$

can be proved, but the law of distribution,

$$a(b + c) = ab + ac, \quad a + bc = (a + b)(a + c),$$

it is not possible to demonstrate without the assumption of an additional principle, or axiom, namely $a(b + c) \leq ab + ac$.

The distributive law has for corollaries the following formulae:

$$\begin{aligned} ab + cd &= (a + c)(b + d)(a + d)(b + d), \\ (a + b)(c + d) &= ac + bc + ad + bd. \end{aligned}$$

These formulae, as well as all those already given, show that there is a perfect correlation, or duality, between addition and multiplica-

tion, which consists in the fact that the signs + and \times may be interchanged upon the condition of interchanging at the same time the special terms 0 and 1, and inverting the sign of inclusion, \leq .

The following formulae may also be demonstrated:

$$\begin{aligned} (a \leq b)(c \leq d) &\leq (ac \leq bd) \\ &\leq (a + c \leq b + d) \\ (a = b)(c = d) &\leq (ac = bd) \\ &\leq (a + c = b + d); \end{aligned}$$

these enable us to combine (but not without loss) several inclusions or equalities by either adding or multiplying them member by member (as in algebra). It is also possible to add a common term to each member of an inclusion or an equation (but not to take one away) and to introduce a common term as a factor (but not to remove one).

The operation of negation adds important properties to the algebra, of which the principals are: the law of double negation, $\bar{\bar{a}} = a$ (C.I.: Non-non- a is identical with a ; P.I.: To deny the denial of a statement is the same as to affirm it); the formulae of De Morgan,

$$\overline{ab} = \bar{a} + \bar{b}, \quad \overline{a + b} = \bar{a}\bar{b},$$

which enable us to distribute the process of denying upon the elements of a sum or of a product (and which illustrates the duality mentioned above), and the principle of contraposition,

$$\begin{aligned} a \leq b &= (\bar{b} \leq \bar{a}), \\ (a \leq b) &= \bar{b} \leq \bar{a} \end{aligned}$$

(C.I.: 'All a is b ' is the same thing as 'All non- b is non- a '; 'Not all a is b ' is the same thing as 'Not all non- b is non- a '; P.I.: 'If a is true b is true' has the same validity as 'If b is false a is false'; that 'The truth of a does not entail the truth of b ' is equivalent to saying that 'The falsity of b does not entail the falsity of a '). As a corollary to this we may add

$$(a = b) = (\bar{a} = \bar{b}).$$

The principle of contraposition is merely a special case of the principle of TRANSPOSITION (q.v.), that is, of

$$\begin{aligned} (ac \leq b + d) &= (a\bar{d} \leq b + \bar{c}), \\ (ac \leq b + d) &= (a\bar{d} \leq b + \bar{c}), \end{aligned}$$

which may be stated thus: an element of a sum in a predicate is the same thing as its negative as a factor of the subject, both in the universal and in the particular statement in terms of this copula. (But the opposite relation does not hold—an element of a sum cannot be introduced in this way into a subject nor a factor into a predicate.)

The formulae for the addition and the multiplication of 0 and 1,

$$0 + x = x, \quad 1 + x = 1,$$

$$0 \times x = 0, \quad 1 \times x = x,$$

lead to the formulae of development, which were given by Boole,

$$x = x(a + \bar{a})(b + \bar{b}) \dots \\ = xab \dots + xab \dots + x\bar{a}b \dots + x\bar{a}\bar{b} \dots,$$

$$x = x + a\bar{a} + b\bar{b} + \dots \\ = (x + a + b)(x + a + \bar{b})(x + \bar{a} + b) \dots,$$

$$0 = (a + b)(a + \bar{b})(\bar{a} + b)(\bar{a} + \bar{b}),$$

$$1 = ab + a\bar{b} + \bar{a}b + \bar{a}\bar{b}$$

$$= abc + ab\bar{c} + a\bar{b}c + \dots,$$

and so for any number of simple terms, a, b, c, \dots (The terms of the development of 1 are called its *constituents*.)

To Boole is due also the formula for the development of a function in terms of any variable, or unknown quantity, x , which it contains: $F(x) = F(1)x + F(0)\bar{x}$, $F(1)$ being what $F(x)$ becomes for $x = 1$, and $F(0)$ being what $F(x)$ becomes for $x = 0$. Hence one of the normal forms for a logical statement (in one unknown quantity) is

$$ax + b\bar{x} \leq 0,$$

which may equally well be written (since $0 \leq F(x)$ is always true, no matter what $F(x)$ may be),

$$ax + b\bar{x} = 0,$$

or,

$$\bar{a}x + \bar{b}\bar{x} = 1.$$

In order to reduce the problems of logic to inclusions or equations of this form, it is necessary to apply to the premises (into which the verbal data have been translated) the preceding formulae of transformation, and to bring them thus into forms in which the second member is either 0 or 1; they are then to be combined in accordance with the following formulae:

$$(a = 0)(b = 0) = (a + b = 0),$$

$$(a = 1)(b = 1) = (ab = 1),$$

until there is only a single equation to be resolved, of one or the other of the two forms,

$$ax + b\bar{x} = 0, \quad (a + x)(b + \bar{x}) = 1.$$

We shall confine ourselves to the treatment of the first of these two forms (the reader can easily translate it, step by step, into the treatment for the second form). The equation is equivalent to this system of two inclusions,

$$ax \leq 0, \quad b\bar{x} \leq 0,$$

or,

$$x \leq \bar{a}, \quad b \leq x,$$

that is to say, to $b \leq x \leq \bar{a}$, (S₁)

whence $b \leq \bar{a}$, or, $ab \leq 0$. (S₂)

Thus the solution is, in words, x contains b and is contained in \bar{a} , or, as it can be otherwise expressed,

$$x = \bar{a}x + b\bar{x} \text{ (Poretsky),}$$

$$x = \bar{a}u + b\bar{u} \text{ (Schröder).}$$

(In the last expression u is a purely arbitrary term.) The two extreme values of x for $u = 1$ and $u = 0$ are $x = b$, $x = \bar{a}$. But the solution of the equation in terms of x is given completely in (S₁), and (S₂) contains all that is involved in the premises independently of x , that is, it is the resultant which remains after the elimination of x . It is also the condition for the resolvability of the original expression.

[But the problem of eliminating x appears in a still more interesting form if we equate to 0 a *sum* and to 1 a *product* of functions of x and \bar{x} , if we write, that is, for the canonical form of the equations to be resolved,

$$(a + x)(b + \bar{x}) = 0, \quad ax + b\bar{x} = 1,$$

instead of those just given. The rule for the elimination of the quantity to be discarded is then exactly the same for both of these expressions; it is simply: *erase it*. (Of course, if either a or b is zero in the left-hand form or 1 in the right-hand form, x cannot be eliminated, for we have then only one premise instead of two.) Moreover, this same rule applies to the elimination of the unknown quantity in the particular propositions,

$$ax + b\bar{x} \neq 0, \quad 1 \neq (a + x)(b + \bar{x});$$

they give, respectively, $a + b \neq 0$, $1 \neq ab$. The argument is here (1) If some a is x or else some b is non- x , then in any case something is either a or b ; and (2) If not everything is at once either a or x and also b or \bar{x} , then, all the more, Not everything is at once a and b . The first of these two forms is probably more convincing intuitively than the second.—C.L.F.]

The common syllogism, when universal, is a particular case of the equations just discussed, if a and b are simple terms, instead of expressions of any degree of complexity. These formulae do not, of course, constitute a demonstration of the principle of the syllogism, for they depend upon it.

The formulae of symbolic logic have usually been developed in terms of the non-symmetrical affirmative copula, $a \leq b$, and its denial, $a \not\leq b$; this method is the best in point of naturalness, but either of the universal symmetrical copulas (see PROPOSITION, in loc.) combined with either of the corresponding particular copulas gives an algebra which has great advantage in point of conciseness; a single formula takes the place, throughout, of the dual pair of formulae of Schröder (see *Studies in Logic*, by members of the Johns Hopkins University.)

Exact logic does not admit the deduction

from the universal affirmative proposition, $a \leq b$, of 'Some b is a ' nor of 'Some a is b '; for the proposition $a \leq b$ does not imply the existence of a , since it is true (no matter what may be the meaning of b) for the value $a = 0$, while 'Some a is b ' and 'Some b is a ' ($ab \leq 0$) do imply the existence of a , since

$$(a \leq 0) + (b \leq 0) \leq (ab \leq 0).$$

But these two deductions are permissible whenever we are in possession of the additional information that a exists, or that $a \leq 0$.

For we have $(a \leq b) = (a\bar{b} \leq 0)$.

Now $(ab \leq 0)(\bar{a}\bar{b} \leq 0) \leq (a \leq 0)$, Whence, by the principle of transposition, we have $(\bar{a}\bar{b} \leq 0)(a \leq 0) \leq (ab \leq 0)$.

It is by means of this principle of transposition that Mrs. Ladd-Franklin has reduced the traditional fifteen valid moods of the syllogism, or the 8,192 ($= 16 \times 16 \times 16 \times 2$) valid syllogisms which are possible if the full scheme of propositions—as Everything is a , or b , Not all but a is b , &c.—is taken account of, to the single formula

$$(ab = 0)(\bar{b}c = 0)(ac \neq 0) \leq 0,$$

which may be called an Antilogism, and to which corresponds either the universal or the particular syllogism (in all its forms) according as one or another of these three incompatible propositions is transferred to the conclusion,

$$(ab = 0)(\bar{b}c = 0) \leq (ac = 0),$$

$$(ab = 0)(ac \neq 0) \leq (\bar{b}c \neq 0).$$

(See Schröder, *Algebra d. Logik*, § 43, and E. Müller, *Ueber d. Algebra d. Logik*, ii. 19.) Cf. PROPOSITION.

The theorems given hitherto hold equally for concepts and for propositions. But there is a special set of theorems for such propositions as are either *always true* or *always false*. These theorems follow from the two following formulae, which constitute the definition of propositions of this kind,

$$A = (1 \leq A), \quad A_1 = (A \leq 0)$$

(with capital letters it is convenient to write a dash for the sign of negation), or, as they may also be written,

$$A = (1 = A), \quad A_1 = (A = 0).$$

These propositions, that is to say, have only two values, 0 and 1. Propositions of variable value are such as contain one or several indeterminate quantities (x, y, z, \dots), for some values of which the propositions are true, for others false. They have an intermediate extension (Gültigkeitsbereich) between 0 and 1, measured mathematically by their probability.

The following formulae hold for propositions of constant value:

$$(1 = A + B) = (1 = A) + (1 = B),$$

$$(AB = 0) = (A = 0) + (B = 0),$$

$$(A \leq B) = (A_1 + B).$$

In the last of these equations we permit ourselves to write (following a peculiarity of language) simply $A_1 + B$ instead of $1 \leq A_1 + B$. To take an example, the proposition ' u is v implies that x is y ' becomes, upon transposition of the first member, 'What is possible is that u is not v or else that x is y ', a statement which we are in the habit of using in the apocopated form, ' u is not v or x is y .' This abbreviation amounts, in the algebra, to the convention that whatever expression, a , shall be simply written upon our sheet of paper shall be understood to have the force of the statement $1 \leq a$; we might equally well, if we had adopted the negative copula, agree that whatever, x , is written upon the paper has the force of $x \leq 0$. Neither procedure would be permissible if particular propositions, the denials of universal propositions, were to be treated at the same time, but by hypothesis we are here dealing only with statements which have no other values than 0 and 1, that is, which are universal.

We have, again,

$$(A = B) = AB + AB_1,$$

$$(A = B_1) = AB_1 + A_1B,$$

and also, $(AB \leq C) = (A \leq C) + (B \leq C)$,

$$(C \leq A + B) = (C \leq A) + (C \leq B),$$

and the theorem due to Mr. Peirce,

$$(AB \leq C) = [A \leq (B \leq C)] \\ = [B \leq (A \leq C)],$$

and finally the principle of hypothetical reasoning, direct and inverse,

$$(A \leq B) A \leq B, \quad (A \leq B) B_1 \leq A_1.$$

For propositions of variable value another notation may be used. Let $f(x)$ be a logical function containing the variable x , which is capable of taking the several values a, b, c, \dots , and let

$$\Sigma_x f(x) = f(a) + f(b) + f(c) + \dots,$$

$$\Pi_x f(x) = f(a) \times f(b) \times f(c) \times \dots;$$

then the equations

$$\Sigma_x f(x) = 0, \quad \Pi_x f(x) = 0,$$

signify, the first, that for every one of the values of x the equation $f(x) = 0$ is satisfied; the second, that for some one at least of its values the equation is satisfied. The formula for the solution of equations given above becomes, in this notation,

$$(ax + b\bar{x} = 0) = (ab = 0) \Sigma_u (x = \bar{a}u + b\bar{u}),$$

which means that if the equation $ax + b\bar{x} = 0$

holds, then on the one hand $ab = 0$, and on the other hand for every one of the values of u , $x = \bar{a}u + b\bar{u}$ satisfies the equation, and reciprocally.

Symbolic logic, it will be seen, constitutes a real algebra, which has its own laws; it gives rise to a theory of equations and of inequalities which has not yet been fully worked out. It also serves as an introduction to a more general logic—the logic of RELATIVES (q. v.)—of which it is a particular case. This latter was foreseen by Leibniz, prepared for by De Morgan, founded by Peirce, and developed by Schröder.

Besides the system of symbolic logic here developed, to which the writings of Johnson, Whitehead, Poretsky, Mitchell, and Mrs. Ladd-Franklin have contributed, the principal systems that have been proposed are (1) that of Jevons, which consists in forming all possible combinations of positive and negative factors (the constituents of Boole), suppressing those which are annulled by the given premises, and reuniting the remaining combinations to form the solution of the problem (an operation which may be facilitated by diagrams and by a logical machine); (2) that of Peirce, whose method consists in separating the combined data up into the product (instead of the sum) of a function of x and of non- x , and in eliminating x by means of the formula

$$(ax \leq b)(c\bar{x} \leq d) \leq (ac \leq b + d);$$

(3) that of MacColl, which consists in considering propositions alone as the elements of reasoning, and in assigning to them three distinct values: $\epsilon(1)$, $\eta(0)$, θ (neither 1 nor 0)—this method is particularly adapted to questions of probability and to certain questions of mathematics (the calculus of the limits of a multiple integral), which in fact gave rise to it; (4) that of Peano, the object of which is to analyse and to verify the propositions of mathematics, and which employs, besides the logical symbols (necessarily different from the preceding, but nearly equivalent to them), symbols for mathematical notions and relations.

(L.C.—C.L.F.)

If symbolic logic be defined as logic—for the present only deductive logic—treated by means of a special system of symbols, either devised for the purpose or extended to logical from other uses, it will be convenient not to confine the symbols used to algebraic symbols, but to include some graphical symbols as well.

[The reader will observe that the symbols

adopted for the dictionary are in some measure departed from in what follows.—J.M.B.]

The first requisite to understanding this matter is to recognize the purpose of a system of logical symbols. That purpose and end is simply and solely the investigation of the theory of logic, and not at all the construction of a calculus to aid the drawing of inferences. These two purposes are incompatible, for the reason that the system devised for the investigation of logic should be as analytical as possible, breaking up inferences into the greatest possible number of steps, and exhibiting them under the most general categories possible; while a calculus would aim, on the contrary, to reduce the number of processes as much as possible, and to specialize the symbols so as to adapt them to special kinds of inference. It should be recognized as a defect of a system intended for logical study that it has two ways of expressing the same fact, or any superfluity of symbols, although it would not be a serious fault for a calculus to have two ways of expressing a fact.

There must be operations of transformation. In that way alone can the symbol be shown determining its interpretant. In order that these operations should be as analytically represented as possible, each elementary operation should be either an insertion or an omission. Operations of commutation, like $xy \therefore yx$, may be dispensed with by not recognizing any order of arrangement as significant. Associative transformations, like $(xy)z \therefore x(yz)$, which is a species of commutation, will be dispensed with in the same way; that is, by recognizing an equiparant as what it is, a symbol of an unordered set.

It will be necessary to recognize two different operations, because of the difference between the relation of a symbol to its object and to its interpretant. Illative transformation (the only transformation relating solely to truth that a system of symbols can undergo) is the passage from a symbol to an interpretant, generally a partial interpretant. But it is necessary that the interpretant shall be recognized without the actual transformation. Otherwise the symbol is imperfect. There must, therefore, be a sign to signify that an illative transformation would be possible. That is to say, we must not only be able to express 'A therefore B,' but 'If A then B.' The symbol must, besides, separately indicate its object. This object must be indicated by a sign, and the relation of this to the significant element of the symbol is that both are

signs of the same object. This is an equi-parant, or commutative relation. It is therefore necessary to have an operation combining two symbols as referring to the same object. This, like the other operation, must have its actual and its potential state. The former makes the symbol a proposition ' A is B ,' that is, ' $\text{Something } A \text{ stands for, } B \text{ stands for.}$ ' The latter expresses that such a proposition *might* be expressed, ' $\text{This stands for something which } A \text{ stands for and } B \text{ stands for.}$ ' These relations might be expressed in roundabout ways; but two operations would always be necessary. In Jevons's modification of Boole's algebra the two operations are aggregation and composition. Then, using non-relative terms, ' nothing ' is defined as that term which aggregated with any term gives that term, while ' what is ' is that term which compounded with any term gives that term. But here we are already using a third operation; that is, we are using the relation of equivalence; and this is a composite relation. And when we draw an inference, which we cannot avoid, since it is the end and aim of logic, we use still another. It is true that if our purpose were to make a calculus, the two operations, aggregation and composition, would go admirably together. Symmetry in a calculus is a great point, and always involves superfluity; as in homogeneous co-ordinates and in quaternions. Superfluities which bring symmetry are immense economies in a calculus. But for purposes of analysis they are great evils.

A proposition *de inesse* relates to a single state of the universe, like the present instant. Such a proposition is altogether true or altogether false. But it is a question whether it is not better to suppose a general universe, and to allow an ordinary proposition to mean that it is sometimes or possibly true. Writing down a proposition under certain circumstances asserts it. Let these circumstances be represented in our system of symbols by writing the proposition on a certain sheet. If, then, we write two propositions on this same sheet, we can hardly resist understanding that both are asserted. This, then, will be the mode of representing that there is something which the one and the other represent—not necessarily the same quasi-instantaneous state of the universe, but the same universe. If writing A asserts that A may be true, and writing B that B may be true, then writing both together will assert that A may be true and that B may be true.

By a *rule* of a system of symbols is meant a permission under certain circumstances to make a certain transformation; and we are to recognize no transformations as elementary except writing down and erasing. From the conventions just adopted, it follows, as RULE I, that *anything written down may be erased, provided the erasure does not visibly affect what else there may be which is written along with it.*

Let us suppose that two facts are so related that asserting the one gives us the right to assert the other, because if the former is true, the latter must be true. If A having been written, we can add B , we may then, by our first rule, erase A ; and consequently A may be transformed into B by two steps. We shall need to express the fact that writing A gives us a right, under all circumstances, to add B . Since this is not a reciprocal relation, A and B must be written differently; and since neither is positively asserted, neither must be written so that the other could be erased without affecting it. We need some place on our sheet upon which we can write a proposition without asserting it. The present writer's habit is to cut it off from the main sheet by enclosing it within an oval line; but in order to facilitate the printing, we will here enclose it in square brackets. In order, then, to express that ' $\text{If } A \text{ can under any circumstances whatever be true, } B \text{ can under some circumstances be true,}$ ' we must certainly enclose A in square brackets. But what are we to do with B ? We are not to assert positively that B can be true; yet it is to be more than hypothetically set forth, as A is. It must certainly, in some fashion, be enclosed within the brackets; for were it detached from the brackets, the brackets with their enclosed A could, by Rule I, be erased; while in fact the dependence upon A cannot be omitted without danger of falsity. It is to be remarked that, in case we can assert that ' $\text{If } A \text{ can be true, } B \text{ can be true,}$ ' then, *a fortiori*, we can assert that ' $\text{If both } A \text{ and } C \text{ can be true, } B \text{ can be true,}$ ' no matter what proposition C may be. Consequently, we have, as RULE II, that, *within brackets already written, anything whatever can be inserted.* But the fact that ' $\text{If } A \text{ can be true, } B \text{ can be true}$ ' does not generally justify the assertion ' $\text{If } A \text{ can be true, both } B \text{ and } D \text{ are true}$ '; yet our second rule would imply that, unless the B were cut off, in some way, from the main field within the brackets. We will therefore enclose B in parentheses, and

express the fact that 'If A can be true, B can be true' by

$$[A(B)] \text{ or } [(B)A] \text{ or } \left[\begin{array}{c} A \\ (B) \end{array} \right], \text{ \&c.}$$

The arrangement is without significance. The fact that 'If A can be true, both B and D can be true,' or $[A(BD)]$, justifies the assertion that 'If A is true B is true,' or $[A(B)]$. Hence the permission of Rule I may be enlarged, and we may assert that anything unenclosed or enclosed both in brackets and parentheses can be erased if it is separate from everything else. Let us now ask what $[A]$ means. Rule II gives it a meaning; for by this rule $[A]$ implies $[A(X)]$, whatever proposition X may be. That is to say, that $[A]$ can be true implies that 'If A can under any circumstances be true, then anything you like, X , may be true.' But we may like to make X express an absurdity. This, then, is a *reductio ad absurdum* of A ; so that $[A]$ implies, for one thing, that A cannot under any circumstances be true. The question is, Does it express anything further? According to this, $[A(B)]$ expresses that $A(B)$ is impossible. But what is this? It is that A can be true while something expressed by (B) can be true. Now, what can it be that renders the fact that 'If A can ever be true, B can sometimes be true' incompatible with A 's being able to be true? Evidently the falsity of B under all circumstances. Thus, just as $[A]$ implies that A can never be true, so (B) implies that B can never be true. But further, to say that $[A(B)]$, or 'If A is ever true, B is sometimes true,' is to say no more than that it is impossible that A is ever true, B being never true. Hence, the square brackets and the parentheses precisely deny what they enclose. A logical principle can be deduced from this: namely, if $[A]$ is true $[A(X)]$ is true. That is, if A is never true, then we have a right to assert that 'If A is ever true, X is sometimes true,' no matter what proposition X may be. Square brackets and parentheses, then, have the same meaning. Braces may be used for the same purpose. Moreover, since two negatives make an affirmative, we have, as RULE III, that *anything can have double enclosures added or taken away, provided there be nothing within one enclosure but outside the other*. Thus, if B can be true, so that B is written, Rule III permits us to write $[(B)]$, and then Rule II permits us to write $[X(B)]$. That is, if B is sometimes true, then 'If X is ever true, B is sometimes true.' Let us make the apodosis

of a conditional proposition itself a conditional proposition. That is, in $(C\{D\})$ let us put for D the proposition $[A(B)]$. We thus have $(C\{[A(B)]\})$. But, by Rule III, this is the same as $(CA(B))$.

All our transformations are analysed into insertions and omissions. That is, if from A follows B , we can transform A into AB and then omit the B . Now, by Rule I, from AB follows A . Treating this in the same way, we first insert the conclusion and say that from AB follows ABA . We thus get as RULE IV that *any detached portion of a proposition can be iterated*.

It is now time to reform Rule II so as to state in general terms the effect of enclosures upon permissions to transform. It is plain that if we have written $[A(B)]C$, we can write $[A(BC)]C$, although the latter gives us no right to the former. In place, then, of Rule II we have:

RULE II (amended). *Whatever transformation can be performed on a whole proposition can be performed upon any detached part of it under additional enclosures even in number, and the reverse transformation can be performed under additional enclosures odd in number.*

But this rule does not permit every transformation which can be performed on a detached part of a proposition to be performed upon the same expression otherwise situated.

Rule IV permits, by virtue of Rule II (amended), all iteration under additional enclosures and erasure of a term inside enclosures if it is iterated outside some of them.

We can now exhibit the *modi tollens et ponens*. Suppose, for example, we have these premises: 'If A is ever true, B is sometimes true,' and ' B is never true.' Writing them, we have $[A(B)](B)$. By Rule IV, from (B) we might proceed to $(B)(B)$. Hence, by Rule II (amended), from $[A(B)](B)$ we can proceed to $[A](B)$, and by Rule I to $[A]$. That is, ' A is never true.' Suppose, on the other hand, our premises are $[A(B)]$ and A . As before, we get $[(B)]A$, and by Rule III, BA , and by Rule I, B . That is, from the premises of the *modus ponens* we get the conclusion. Let us take as premises 'If A is ever true, B is sometimes true,' and 'If B is ever true, C is sometimes true.' That is, $(A\{B\})[B(C)]$. Then, iterating $[B(C)]$ within two enclosures, we get $(A\{B[B(C)]\})[B(C)]$, or, by Rule I, $(A\{B[B(C)]\})$. But we have just seen that $B[B(C)]$ can be transformed to C . Performing this under two enclosures, we get $(A\{C\})$, which is the conclusion, 'If A is

ever true, C is sometimes true.' Let us now formally deduce the principle of contradiction $[A(A)]$. Start from any premise X . By Rule III we can insert $[(X)]$, so that we have $X[(X)]$. By insertion under odd enclosures we have $X[A(X)]$. By iteration under additional enclosures we get $X[A(A X)]$, by erasures under even enclosures $[A(A)]$.

In complicated cases the multitude of enclosures become unmanageable. But by using ruled paper and drawing lines for the enclosures, composed of vertical and horizontal lines, always writing what is more enclosed lower than what is less enclosed, and what is evenly enclosed on the left-hand part of the sheet, and what is oddly enclosed on the right-hand part, this difficulty is greatly reduced. The following diagram illustrates the general style of arrangement recommended.

It is now time to make an addition to our system of symbols. Namely, AB signifies that A is at some quasi-instant true, and that B is at some quasi-instant true. But we wish to be able to assert that A and B are true at the same quasi-instant. We should always study to make our representations iconoidal; and a very iconoidal way of representing that there is one quasi-instant at which both A and B are true will be to connect them with a heavy line drawn in any shape, thus:

$$A-B \text{ or } \begin{array}{c} A \\ \hline B \end{array}$$

If this line be broken, thus $A--B$, the identity ceases to be asserted. We have evidently—

RULE V. *A line of identity may be broken*

where unenclosed. $-A$ will mean 'At some quasi-instant A is true.' It is equivalent to A simply. But $\neg(A)$ will differ from $(-A)$ or (A) in merely asserting that at some quasi-instant A is not true, instead of asserting with the latter forms that at no quasi-instant is A true. Our quasi-instants may be individual things. In that case $-A$ will mean 'Something is A '; $\neg(A)$, 'Something is not A '; $[(A)]$, 'Everything is A '; $(-A)$, 'Nothing is A .' So $A-B$ will express 'Some A is B '; $(A-B)$, 'No A is B '; $A\neg(B)$, 'Some A is not B '; $[A\neg(B)]$, 'Whatever A there may be is B '; $(A)(B)$, 'There is something besides A and B '; $[(A)(B)]$, 'Everything is either A or B .' The rule of iteration must now be amended as follows.

RULE IV (amended). *Anything can be iterated under the same enclosures or under*

additional ones, its identical connections remaining identical.

Thus, $[A\neg(B)]$ can be transformed to $[A(A\neg B)]$. By the same rule $A--(-B)$, i.e. 'Something is A and nothing is B ,' by iteration of the line of identity, can be transformed to $A\neg(\neg B)$, i.e. 'Some A is not coexistent with anything that is B ,' whence, by Rules V and II (amended), it can be further transformed to $A\neg(\neg B)$, i.e. 'Some A is not B .'

But it must be most carefully observed that two unenclosed parts cannot be illatively united by a line of identity. The enclosure of such a line is that of its least enclosed part. We can now exhibit any

ordinary syllogism. Thus, the premises of *Baroko*, 'Any M is P ' and 'Some S is not P ', may be written $\{M[P]\} S(P)$. Then, as just seen, we can write $\{M[P]\} S(P)$. Then, by iteration, $\{M[P(P)]\} S(P)$. Breaking the line under even enclosures, we get $\{[P(P)]M\} S(P)$. But we have already shown that $[P(P)]$ can be written unenclosed. Hence it can be struck out under one enclosure; and the unenclosed (P) can be erased. Thus we get $\{M\} S$, or 'Some S is not M .' The great number of steps into which syllogism is thus analysed shows the perfection of the method for purposes of analysis.

In taking account of relations, it is necessary to distinguish between the different sides of the letters. Thus let l be taken in such a sense that $X-l-Y$ means ' X loves Y .'

Then $X \overline{l} Y$ will mean ' Y loves X .' Then, if m means 'Something is a man,' and w means 'Something is a woman,' $m-l-w$ will mean 'Some man loves some woman'; $m \overline{[l]} w$ will mean 'Some man loves all women'; $[(m-l)w]$ will mean 'Every woman is loved by some man,' &c.

Since enclosures signify negation, by enclosing a part of the line of identity, the relation of otherness is represented. Thus, $A \overline{[]} B$ will assert 'Some A is not some B .' Given the premises 'Some A is B ' and 'Some C is not B ,' they can be written $A-B \overline{C}(B)$. By Rule III, this can be written $A \{[B]\} \overline{C}(B)$. By iteration, this gives $A \{[B(B)]\} \overline{C}(B)$. The lines of identity are to be conceived as passing through the space between the braces outside of the brackets. By breaking the lines under even enclosures, we get $A \overline{[]} [B(B)] \overline{C}(B)$. As we have already seen, oddly enclosed $[B(B)]$ can be erased. This, with erasure of the detached (B) , gives $A \overline{[]} \overline{C}$. Joining the lines under odd enclosures, we get $A \overline{[]} \overline{C}$, or 'Some A is not some C .'

For all considerable steps in ratiocination, the reasoner has to treat qualities, or collections (they only differ grammatically), and especially relations, or systems, as objects of relation about which propositions are asserted

and inferences drawn. It is, therefore, necessary to make a special study of the logical relatives '— is a member of the collection —,' and '— is in the relation — to —.' The key to all that amounts to much in symbolical logic lies in the symbolization of these relations. But we cannot enter into this extensive subject in this article.

The system of which the slightest possible sketch has been given is not so iconoidal as the so-called Euler's diagrams; but it is by far the best *general* system which has yet been devised. The present writer has had it under examination for five years with continually increasing satisfaction. However, it is proper to notice some other systems that are now in use. Two systems which are merely extensions of Boole's algebra of logic may be mentioned. One of these is called by no more proper designation than the 'general algebra of logic.' The other is called 'Peirce's algebra of dyadic relatives.' In the former there are two operations—aggregation, which Jevons (to whom its use in algebra is due) signifies by a sign of division turned on its side, thus $\cdot|$ (I prefer to join the two dots, in order to avoid mistaking the single character for three); and composition, which is best signified by a somewhat heavy dot, \cdot .

Thus, if A and B are propositions, $A \cdot| B$ is the proposition which is true if A is true, is true if B is true, but is such that if A is false and B is false, it is false. $A \cdot B$ is the proposition which is true if A is true and B is true, but is false if A is false and false if B is false. Considered from an algebraical point of view, which is the point of view of this system, these expressions $A \cdot| B$ and $A \cdot B$ are *mean functions*; for a mean function is defined as such a symmetrical function of several variables, that when the variables have the same value, it takes that same value. It is, therefore, wrong to consider them as addition and multiplication, unless it be that *truth* and *falsity*, the two possible states of a proposition, are considered as logarithmic infinity and zero. It is therefore well to let \circ represent a false proposition and ∞ (meaning logarithmic infinity, so that $+\infty$ and $-\infty$ are different) a true proposition. A heavy line, called an 'obelus,' over an expression negatives it.

The letters i, j, k , &c., written below the line after letters signifying predicates, denote individuals, or supposed individuals, of which the predicates are true. Thus, l_{ij} may mean that i loves j . To the left of the expression a series of letters Π and Σ are written, each

with a special one of the individuals i, j, k attached to it in order to show in what order these individuals are to be selected, and how. Σ_i will mean that i is to be a suitably chosen individual, Π_j that j is any individual, no matter what. Thus,

$$\Sigma_i \Pi_j l_{ji}$$

means that there is an individual i such that every individual j loves i ; and

$$\Pi_j \Sigma_i l_{ji}$$

will mean that taking any individual j , no matter what, there is some individual i , whom j loves. This is the whole of this system, which has considerable power. This use of Σ and Π was probably first introduced by O. C. Mitchell in his epoch-making paper in *Studies in Logic*, by members of the Johns Hopkins University.

In Peirce's algebra of dyadic relatives the signs of aggregation and composition are used; but it is not usual to attach indices. In place of them two relative operations are used. Let l be 'lover of,' s 'servant of.' Then ls , called the relative product of s by l , denotes 'lover of some servant of'; and $l \div s$, called the relative sum of l to s , denotes 'lover of whatever there may be besides servants of.' In MS. the tail of the cross will naturally be curved. The sign $|$ is used to mean 'numerically identical with,' and \top to mean 'other than.' Schröder, who has written an admirable treatise on this system (though his characters are very objectionable, and should not be used), has considerably increased its power by various devices, and especially by writing, for example, Π before an expression containing u to signify that u may be any relative whatever, or Σ to signify that it is a possible relative. In this way he introduces an abstraction or term of second intention. (C.S.P.)

Peano has made considerable use of a system of logical symbolization of his own. Mrs. Ladd-Franklin advocates eight copulatives to begin with, in order to exhibit the equal claim to consideration of the eight propositional forms. Of these she chooses 'No a is b ' and 'Some a is b ' ($a \bar{\vee} b$ and $a \vee b$) as most desirable for the elements of an algorithmic scheme; they are both symmetrical and natural. She thinks that a symbolic logic which takes 'All a is b ' (Boole, Schröder) as its basis is cumbersome; for every statement of a theorem, there is a corresponding statement necessary in terms of its contrapositive. This, she says, is the source of the parallel columns of theorems in Schröder's *Logik*; a single set of theorems is all-sufficient if a symmetrical

pair of copulas is chosen. Some logicians (as C.S.P.) think the objections to Mrs. Ladd-Franklin's system outweigh its advantages. Other systems, as that of Wundt, show a complete misunderstanding of the problem. Cf. SYLLOGISM (2). (C.S.P., C.L.F.)

Symbolic logic finds occasion to single out two terms as of peculiar significance, and to represent them by the special symbols. o (zero) and ∞ (infinity); all other terms have both application and signification, but the first of these has no object of consciousness to which it is applicable, and simply signifies the non-existent, while the second has every object of consciousness as its application, and has no signification whatever. These properties are expressed in formal language by saying that

$$a \leq \infty, o \leq a$$

are, no matter what a may be, propositions of no content, though always true. But

$$\infty \leq a, \bar{a} \leq o$$

state, the first, that everything is a , and the second, that \bar{a} is non-existent. These last two propositions are contrapositives one of the other, and ∞ and o are a pair of contradictory terms (i. e. each is the negative of the other). Much confusion would be saved in discussions in non-symbolic logic by the recognition of these special terms. (C.L.F.)

Symbolical: Ger. *symbolisch*; Fr. *symbolique*; Ital. *simbolico*. (1) Relating to symbols in the general sense. See SYMBOL (1).

(2) Relating to symbols, novel or peculiar.

In this sense the treatment of logic by means of peculiar characters or old characters put to peculiar uses is by some writers called SYMBOLIC(AL) LOGIC (q.v.).

(3) Relating to an algebraical method in which operations are denoted by letters and made the subject of operations. (C.S.P.)

Symbolism: Ger. *Symbolismus*; Fr. *symbolisme*; Ital. *simbolismo*. (1) In aesthetics: (a) symbols considered abstractly; (b) the theory of the nature and use of the SYMBOL (q.v. 2).

(2) In religion: the use of objects in a symbolic sense; that is, as sensuous emblems of spiritual acts and objects; as, for example, ritual in worship and the sacraments in one aspect of their significance.

Symbolism in this sense has a wide use in religion, the objects of which are unseen and intangible. Hence the need of helping the imagination by means of sensuous objects which may serve as fitting materializations of the spiritual. Symbolism enters into every phase of religion, including the architecture of its churches and temples. The significance of sacred architecture is never wholly that of adaptation to certain functions, but it is determined also to a degree by the spiritual

import of those functions and by the influence of religious ideas. (A.T.O.)

Literature: see SYMBOL; also G. FERRERO, *I simboli* (1892); G. MARCHESINI, *Il simbolismo* (1901). (E.M.)

Symbols (and **Symbolics**) [Gr. *σύμβολον*, a sign]: Ger. *Symbole*; Fr. *symboles*; Ital. *simboli*. The authoritative doctrines or creeds of the Christian Church. Symbolics: a department of ecclesiastical history which treats of the origin, history, and contents of the various creeds of Christendom.

The term symbol was first employed in a theological sense by Cyprian in the year 250 A.D., and after the 4th century came into general use. It was first applied to the Apostles' Creed as a military watchword, distinguishing Christians from Pagans. Luther and Melancthon first applied the name to Protestant confessions. Since Reformation times the use has been general.

Literature: OEHLER, *Lehrb. d. Symbolik* (1876); WUNDT, *Symbolik d. römisch-katholischen Kirche* (1880); *Literature in the Creeds* (1878); SCHAFF, *Creeds of Christendom*. (A.T.O.)

Symmetry [Gr. *σύν*, with, + *μέτρον*, measure]: Ger. *Symmetrie*; Fr. *symétrie*; Ital. *simmetria*. The arrangement in reverse order, on opposite sides of a perpendicular line or plane, of like and equal parts of an object. More loosely, the equable distribution of parts in the formation of a balanced whole.

In the latter sense it is almost synonymous with proportion, consistency, and congruity. In the narrower sense applied most appropriately in architecture and sculpture; more ambiguously in drawing and painting. Applied rarely and somewhat metaphorically to canon and fugue in music, referring to the temporal repetition of musically similar passages, to metrical relations, as in the asclepiadic verse, and to the structure of the drama, as involving 'exposition,' 'conflict,' and 'solution.' For closely connected meanings see BALANCE, HARMONY, and PROPORTION.

The Greek term was probably first applied to the commensurability of numbers, thence to the parts of a statue, and finally to the relations of form in general. The aesthetic value of the quality has been recognized by practically all aestheticians from the earliest Greek writers down to the present day. The principle, with its connected categories, harmony and proportion, is, however, so fundamental to the Greek conception of beauty, that it plays relatively a more important

part in their aesthetic doctrines than in those of modern aestheticians. With the latter the importance of these elements is relatively lessened by reason of the value attached to the beautiful as significant, as mediating or revealing the characteristic.

Literature: KÖSTLIN, *Asthetik* (1869); CARRIERE, *Asthetik*, i (1885); SANTAYANA, *Sense of Beauty* (1896). (J.R.A.)

Sympathy [Gr. *σύν* + *παθεῖν*, to suffer]: Ger. *Mitleid*, *Sympathie*; Fr. *sympathie*; Ital. *simpatia*. The emotional disposition aroused by the thought of experience on the part of another, and on occasion issuing in emotion qualitatively the same as that which the other is thought to have from the experience.

Sympathy has played an important rôle in psychology, ethics, and sociology. Its peculiar implication of one's own experience in another individual's serves to attract analysis from the point of view of the social life. It has been considered, on the one hand, a natural altruistic instinct (impulse), and an original 'spring of action'; and on the other hand, a derived product of experience, reflecting the fortunes of self as depicted 'in the shoes' of another. The discussion has more recently taken the form of the genetic question as to the actual origin and function of sympathy, and it has been connected with the phenomena of EJECTION (q.v.; see also SYMPATHY, aesthetic), by which the self is 'read-in' to 'other' persons. This has the advantage of overcoming the dualism of 'self and other' which has always embarrassed writers on sympathy; for on the basis of this dualism it may be asked, why should the fortunes of another excite the emotions which attach to those of myself? So soon as we entertain the view that the thought of myself and that of the other-self are really only thought of a self, variously determined, it follows that the emotions issuing from self as such will be in general the same, so far as the determination of the particular experience does not forbid it. In other words, the problem becomes to account for the differences of emotional and conative reaction to differences of personality rather than to account for the sameness of them; and this is a problem of which the solution lies in the actual accommodations, dispositions, and habits due to experience. The problem becomes that of tracing the differentiation of emotional dispositions into 'private' on the one hand, and 'sympathetic' on the other hand.

In sociology the point is essentially the

same: how can solidarity, social unity, based on sympathy, arise if society is made up of a struggling mass of individuals, each pursuing his own interests under the principle of competition? Cf. INDIVIDUALISM, and RIVALRY. So, in answer to this question, we have various ways of reconciling the dualism of interest of 'one' person and 'another'—'social contract,' 'gregarious instinct,' 'constraint,' 'fellow-feeling' (which assumes sympathy), &c. Of course, since sympathy is a fact, social theory may assume it, and rest the case there, but an adequate social psychology giving an account of sympathy serves as foundation for social philosophy. The view which refutes individualism and makes sympathy a normal reaction to the social environment as such—an evidence of an intrinsic social bond and of a developing SOCIUS (q.v.)—supplies this first desideratum. Cf. SOCIAL ORGANIZATION.

It has been maintained that there is a form of ORGANIC (q.v., in psychology) or spontaneous sympathy which in the child precedes the more reflective form. It seems to be associated with the mere thought of pain or suffering, and to be associated with certain organic expressive movements. This is more notably the case with other reactions to persons (notably BASHFULNESS, q.v.), and is no doubt due to natural selection. Other emotions, as fear, anger, jealousy, seem also to show this genetic distinction of modes. Cf. the genetic analysis of Jones (as cited below).

(J.M.B., G.F.S., W.R.S.)

The significance of sympathy for ethical theory is connected with the important practical distinction between egoistic and altruistic interests. When moral conduct is identified with rational conduct, and the life of reason is separated from the emotional life (as by the Stoics and by Kant), this distinction between egoism and altruism is not regarded as fundamental, and sympathy is not held either to constitute or to lead to morality. But wherever the distinction of egoistic and altruistic conduct has become prominent (as in the English successors and opponents of Hobbes), the part played by sympathy both in determining conduct and in evaluating it has come to be looked upon as of primary importance. The classical contention for the ethical value of sympathy is found in the *Moral Sentiments* of Adam Smith. According to him the effort to sympathize produces both the 'amiable' and the 'noble' virtues of character; and the sympathy of

a 'well-informed and impartial spectator' gives the criterion of morality in conduct. The influence of this doctrine is apparent in the accounts of the formation of the 'conscientious' or 'moral' feelings given by later psychological moralists. The same influence led both Comte and Schopenhauer to regard sympathy as the primary moral phenomenon. Comte sees in it an instinctive tendency to the social life, and, as such, it becomes the basis of his ALTRUISM (q. v.). Schopenhauer calls sympathy the fundamental fact of ethics; but he entirely forsakes the psychological method of Adam Smith in asserting that the fact of sympathy proves the unity of all men, and that individuality is an illusion. (W.R.S.)

Literature: that of ETHICS, SOCIAL PSYCHOLOGY, and much of that of SOCIOLOGY. The classical book is ADAM SMITH, *Theory of the Moral Sentiments*. The psychologies of SPENCER, WUNDT, JODL, LADD, BALDWIN, have chapters on sympathy. Other recent discussions are SUTHERLAND, *Origin and Development of the Moral Instinct*; MEZES, *Princ. of Ethics*; JONES, *Sociality and Sympathy*, *Psychol. Rev.*, Mon. Suppl. (J.M.B.)

Sympathy (aesthetic): Ger. *Miterleben* (cf. TERMINOLOGY, German, 'Einfühlung'), *aesthetische Sympathie* (Lipps); Fr. *sympathie esthétique* (suggested, no exact term—T.H.F.); Ital. *immedesimazione, simpatia estetica*. The feeling-in of a state or experience of one's own into an aesthetic object, together with positive feeling or sympathy with the object.

Lipps says (analysing the aesthetic effect produced by a Doric column): 'I sympathize with the column's manner of holding itself, and attribute to it qualities of life, because I recognize in it proportions and other relations agreeable to me. Thus all enjoyment of form, and indeed all aesthetic enjoyment whatsoever, resolves itself into an agreeable feeling of sympathy' (as cited below, 5); to which Groos adds (as cited below, Eng. trans., 326), that the whole, to be aesthetic, must be 'lingered over only for the sake of its pleasure-giving qualities, i.e. playfully.' The latter author draws an analogy between the child's dramatic (play) imitation and aesthetic sympathy. Groos (*ibid.*, 323) gives also the following analysis of aesthetic sympathy: 'In this very complicated process we can distinguish these leading characteristics: i a. The mind conceives of the experience of the other individual as if it were its own. i b. We live through the psychic states which a lifeless object would experience if it possessed a mental

life like our own. ii a. We inwardly participate in the movements of an external object. ii b. We also conceive of the motions which a body at rest might make if the powers which we attribute to it were actual (the fluidity of form). iii. We transfer the temper, which is the result of our own inward sympathy, to the object, and speak of the solemnity of the sublime, the gaiety of beauty, &c. By including all these under the rather inadequate name of aesthetic sympathy, . . . &c.' Cf. the analysis made by Witasek (as cited below); given also by Urban, *Psychol. Rev.*, July, 1901.

Literature: JOUFFROY, *Cours d'esthétique* (1845); VOLKELT, *Der Symbolbegriff in d. neuesten Aesthetik* (1876); P. STERN, *Einfühlung u. Association in d. neuern Aesthetik* (1898); LIPPS, *Raumästhetik u. geometr.-optische Täuschungen* (1897); URBAN, *Logic of the Emotions*, *Psychol. Rev.*, May, July, 1901; WITASEK, *Zeitsch. f. Psychol.*, xxv, 1901; RIBOT, *Imagination créatrice* (1900); GROOS, *Die Spiele d. Menschen* (1899; Eng. trans., 1901); LOTZE, *Gesch. d. Aesthetik in Deutschland* (1868), 74-86. See also SYMBOL, and REVIVAL (affective). (J.M.B., J.H.T.)

Symptom [Gr. *σύμπτωμα*, a chance, casualty]: Ger. *Symptom*; Fr. *symptôme*; Ital. *sintomo*. The indications of a disorder; the departures from normal appearance or function which characterize a disease.

In medicine, the general description of such signs, indications, or characteristics is termed the symptomatology of a disease. The distinction is at times drawn between the physical signs or gross bodily indications and the physiological symptoms. An important distinction is between objective symptoms, which are observable (or by suitable means can be rendered observable) to the physician or student, and subjective ones, which are derivable only from the reports of the subject.

Psychologically, the most significant groups of symptoms are the sensory, the motor, and the mental ones. Sensory symptoms characteristic of various diseases are the anaesthesias, hyperaesthesias, and paraesthesias, the limitations of the fields of vision, partial deafness, disorders of the muscle sense (as in ataxia), feelings of vertigo, malaise, headaches, pains, and so on; motor symptoms include paralysis, paresis, spasms, convulsions, contractures, and in speech, stuttering and the various dysphasias and dyslalias; mental symptoms include illusions, hallucinations, irregular and chaotic flow of ideas, perversions of impulses, excessive joy

or depression, moral insensibility, and an indefinite series of deviations from normal thought observable in speech and conduct. [An interesting group is that characterized by negation of many sorts—negativistic ideas, and delusions (*délire de négation*)—very frequent in the depressive psychoses.—E.M.]

The descriptions of a given abnormal state, such as MANIA, MELANCHOLIA, PARALYSIS, PARANOIA, NEURASTHENIA (see those terms), include an account of its typical symptoms. Such a group of symptoms likely to occur together is termed, in German, a *Symptomen-complex*—a useful term also current in English. See PSYCHOSIS, and also what is said of symptoms under MANIA, and MELANCHOLIA.

Syn- [Gr. σύν]: Ger. *Syn-*; Fr. *syn-*; Ital. *sin-*. A prefix indicating together with, accompanying; as in SYNERGY (q.v.), and SYNAESTHESIA (q.v.).

Synaesthesia [Gr. σύν + αἰσθησις, sensation, perception]: Ger. *Synästhesie*, *Mitempfindung* (Stumpf); Fr. *synesthésie*; Ital. *sinestesia*. (1) A general term for the facts of CONCOMITANT SENSATION (q.v.); but, (2) Usually restricted to concomitance of DISPARATE (q.v.) sensations. Here belong the phenomena of coloured hearing or pseudo-chromaesthesia, the photisms of touch, &c. (E.B.T.)

Literally, an accompanying or secondary sensation; the term seems best suited to describe the general class of peculiar and intimate associations between one sense-perception and another, by means of which the appearance or thought of the one brings with it in a regular way the other also. A frequent case is the association of colour with sound, known as colour-hearing, or colour-audition. When persons who have such synaesthesias hear certain musical tones, they see or visualize certain colours, often in definite positions and spread out in space. The tone of a life may be blue, of a violin yellow; high tones may have bright colours and low ones dull colours; the sounds of words or letters as spoken may vividly suggest colours; and in extreme cases there exists an elaborate colour-alphabet corresponding to the sounds of letters or syllables. The reverse associations may also occur by which groups of colours, when seen, suggest letters and their sounds. In a case published by Galton, wall-paper patterns could be read as syllables and words; and Galton's own name was rendered in colours by this subject in terms of his well-developed sound-colour associations. The days, the

months, the seasons, proper names, even smells and tastes may be associated with colours by synaesthesia, so that the perception of one of them induces more or less vividly the visualization of the corresponding colour. Colours seem more apt to be thus associated than any other group of sensations, and these have been termed pseudo-chromaesthesia (see Krohn, as cited below). Flournoy uses the term '*synopsie*' to include all visual synaesthesias. The specific associated light or colour is termed a '*photism*'; the realization of a sound in connection with a given visual or other perception is a '*phonism*.'

Recent investigation has proved the rather wide distribution of such phenomena. They are by no means rare, but well-developed cases of systematic and extensive series of synaesthesia are not the rule. The phenomena exist as idiosyncrasies; one person sees numbers coloured; another letters; a third the hour-marks on the clock; a fourth the days of the week; a fifth the Christian names of friends; a sixth hears tones of the piano in a scale of colours; a seventh gives colours to the voices of those addressing him; and so on indefinitely. Nor do the various colour schemes of those who have similar synaesthesias, e.g. coloured letters, at all agree. The individual constancy for years of the same colour associations in the same person has been repeatedly verified; the same sound assumes practically the same colour on all occasions. Another interesting variation is the '*Number-form*.'

A number-form is the realization of the serial numbers in a definite geometrical position in space. Here, again, there is an indefinite variety, from a simple projection outwards, the larger numbers receding in the distance, to elaborate schemes of spirals and circles, waves and crescents, in complex three-dimensional positions. In each case the number-form is constant for the individual, and often serves as a fixation point in calculations. Letters and numbers are liked or disliked, are conceived as human and endowed with sentimental characteristics, and so on. Synaesthesias of all sorts cannot be regarded as specifically abnormal, certainly not as morbid; but they belong to the realm of the unusual and the idiosyncratic, within which explanation is difficult. Although subjective, they are not hallucinations, and in some measure they form, in the realm of sensation, the counterpart of insistent ideas and motor habits. Cf. IMPERATIVE IDEA.

PLATE I (**Synaesthesia**). Number-forms of four members of the S— family (mother and children).

Mr. R. G. S—.

Seen in horizontal plane in perspective like mountain tops: outline of each ten reproduces 1-10: and first, second, and third, &c., tens in heights follow scale of digits, as sketched in upper left-hand corner.

The explanation of synaesthesia varies between the physiological one, which regards a cortical association between different brain centres as the basis of the associated pseudo-sensations; and the psychological one, which regards it as due to an aggressive and persistent association, in part idiosyncratic and dominated in some cases by a community or analogy of emotional tone. Many cases seem to suggest and to support the latter explanation, while little direct proof of the physiological theory seems available, unless the occasional simultaneous appearance of similar synaesthesias in members of the same family be so regarded. There exist, too, allied groups of such unusual but intimate and spontaneous associations, notably in the number-forms and the personification of inanimate objects. (J.J.)

Cases of hereditary synaesthesia, including number-forms, tell strongly in favour of a 'native' or 'constitutional' (called above the 'physiological') theory. The accompanying Plates I and II, selected by the writer from his collection of unpublished cases, show the number-forms of five members of the same family (of nine, not all reported upon), the mother and four children. To the writer (who has another case of three in the same family) this affords strong proof of the hereditary character of synaesthesia, notably in cases in which—as in one of these cases—other peculiarities, such as coloured letters, are also present (cf. a detailed report, with coloured plate, of twenty-one cases of coloured letters, by Colman, in the *Lancet*, January 1, 1898).

The presence of well-defined synaesthesias in young children, who have had neither the sort nor the quantity of experience to establish the requisite associations, is also of weight as against the psychological or 'experience' view. (J.M.B.)

Literature: a good account of cases with literature is to be found in KROHN, *Pseudochromaesthesia*, in *Amer. J. of Psychol.*, v; see also CALKINS, *Synaesthesia*, *ibid.*, vii; PHILIPS, *Number Forms*, *ibid.*, viii; WHIPPLE, *ibid.*, xi. Valuable are FLOUROY, *Les Phénomènes de Synopsie* (1893); BLEULER and LEHMANN, *Zwangsmässige Lichtempfindungen* durch Schall (1881); GALTON, *Inquiries into Human Faculty* (1883); STUMPF, *Tonpsychologie*, i, ii; MORSELLI, *Semej. malat. ment.*, ii (1895); A. LEMAITRE, *Aud. colorée et Phénom. connexes chez les Écoliers* (1901). (J.J.—E.B.T.)

Synaposematic: see MIMICRY (in biology).

Syncategorematic: see CATEGOREMATIC.

Syncope (or **-pe**) [Gr. *συνκοπή*, a cutting short]: Ger. *Syncope*; Fr. *syncope*; Ital. *sincope*, *deliquio*. A more or less sudden loss of consciousness.

It is owing usually to heart failure, and consequent cerebral anaemia. It may be occasioned by cardiac weakness, or loss of blood; but is often due (especially in persons of nervous diathesis) to emotional causes, such as fear, alarm, grief, joy. In a complete syncopal attack there is first a sensation of sinking or giddiness, upon which the patient loses consciousness and falls to the ground. In this state the pulse and respiration are weak and the face pale. Gradually colour returns, slight movements are made, and recovery takes place. Cf. SHOCK, and PROSTRATION. (J.J.)

Syncretism [Gr. *σύν + κρητίζω*, probably to combine or unite]: Ger. *Synkretismus*; Fr. *synchrétisme*; Ital. *sincretismo*. (1) The attempt to select and combine various elements from a number of philosophic systems without much regard to the intrinsic value of what is selected, or to the logical method of the combination; about the same as eclecticism, but used, upon the whole, in a somewhat more disparaging sense. (J.D.)

(2) In religion: The method of reconciling conflicting principles or interests on the basis of some common ground of interest or belief; abusively, the spirit of indifference or compromise in religion.

In ecclesiastical history the term designates the principles of a party in the Lutheran Church in the 17th century, headed by Calixtus, who laboured to bring about a union of the various branches of the Protestant Church. The attempt was rendered ineffective through persistent opposition, its opponents succeeding in fastening upon its advocates the suspicion of heresy and indifferentism.

Literature: H. SCHMID, *Gesch. d. synkretischen Streitigkeiten* (1846); GASS, *Gesch. d. protest. Dogmatik*, ii (1850); Schaff-Herzog *Cyclopedia*, art. *Syncretism*. (A.T.O.)

Syncryptic: see MIMICRY (in biology).

Synderesis (frequently written **Synteresis**, also **Sinteresis**) [Gr. *συντήρησις*]: Ger. *Synderesis*; Fr. *syndérèse*; Ital. *sinderesi*. A technical term of the scholastic philosophy, signifying the innate principle in the moral consciousness of every man, which directs him to good and restrains him from evil.

In the account of the Stoic philosophy given by Diogenes Laertius (VII. i. 85), τὸ τηρεῖν ἑαυτό, literally 'taking care of oneself,' or self-preservation, is said to be the fundamental impulse of living beings, which is further described by Chrysippus as harmony with oneself, and the consciousness (συνείδησις) of that harmony. But the use of συντήρησις as a technical term is first found in the writings of St. Jerome (d. 420). It occurs in one passage only of these writings—the explanation of the 'four living creatures' of the vision of Ezekiel (i. 4–15). Most commentators, he says, hold that the man, the lion, and the ox of the vision represent the rational, the irascible, and the appetitive (or concupiscent) parts of the soul, according to Plato's division, while the fourth figure, that of the eagle, represents a fourth part of the soul, above and outside these three: 'this the Greeks call συντήρησις, which spark of conscience (scintilla conscientiae) was not extinguished from the breast of Adam when he was driven from Paradise; through it, when overcome by pleasures or by anger, or even, as sometimes, deceived by a similitude of reason, we feel that we sin; . . . and this, in the Scriptures, is sometimes called spirit' (Rom. viii. 26; 1 Cor. ii. 11; 1 Thess. v. 23). 'And yet we perceive that the conscience (conscientia) is itself also thrown aside and driven from its place by someone who have no shame or modesty in their faults.' In this passage no distinction seems to be drawn between συντήρησις and conscientia. It has even been maintained (F. Nitzsch, in *Jahrb. f. protest. Theol.*, iii. 492 ff.; *Zeitsch. f. Kirchengesch.*, XVII. i. 23 ff.) that the former word is a copyist's error for συνείδησις, the usual Greek equivalent of conscientia. For this supposition there is no sufficient evidence; still less can Ziegler's suggestion of τὸν νόμισμα (*Gesch. d. christl. Eth.*, 314) be accepted. The view of Albertus Magnus that the word is derived from σύν and αἴρεσις is absurd.

The use of synderesis as distinct from conscientia among the scholastics, and to a slight extent among early Protestant moralists, is founded upon its description by Jerome as scintilla conscientiae—the spark (as the phrase would require to be interpreted) from which the light of conscience arises. Thus Jeremy Taylor calls it 'the spark or fire put into the heart of man,' while συνείδησις, which is specifically called conscience of the deed done, is the 'bringing fuel to this fire' (*Ductor Dubitantium*, I. i. 1). As dis-

tinguished from synderesis, conscientia is applied by these writers to the particular attitude of a man to good or evil action, and may accordingly be an unsafe guide.

Synderesis is thus a faculty or habit (it was disputed which) both of judging and of willing the right, in agreement with 'original righteousness,' and persisting in the separate powers of the soul in spite of the corruption of man's nature brought about by the Fall. In the earlier descriptions it is spoken of as volitional as well as intellectual. According to Aquinas, however, it is distinctly practical reason—certain principles belonging to the practical side of reason which point out the right direction for action, just as the theoretical axioms of the understanding do for thinking; and both synderesis and conscientia are placed among the intellectual powers. A different view is given by Bonaventura, who makes the whole distinction between conscientia and synderesis rest upon the distinction between judgment and will. God (he says) has implanted a double rule of right in man's nature: one for judging rightly, and this is the rectitude of conscience; another for right volition, and this is the rectitude of synderesis, whose function is to dissuade from evil and stimulate to good, and which may therefore be described as the original moral tendency of the disposition.

This, however, does not seem to be either the best or the most prevalent view of scholasticism regarding synderesis (although Ziegler is of a contrary opinion—*Gesch. d. christl. Eth.*, 312). The question is fully discussed by Duns Scotus, who decided against Bonaventura that both synderesis and conscience belong to (practical) reason, the former giving the first principles or major premises of its practical syllogisms, the latter corresponding to their conclusions (*In Sent. Reportationes*, Lib. II, dist. 39, Q. 1–2). Jeremy Taylor (loc. cit.) also follows the Thomistic usage, and makes συντήρησις 'the general repository of moral principles or measures.' This is the 'rule of conscience,' while conscience itself is 'a conjunction of the universal practical law with the particular moral action.' It applies the rule to the particular case, and is thus both witness and judge of moral actions.

It may be noted that the term conscience, when used (as by Kant) as equivalent to practical reason regarded as infallible, corresponds to the mediaeval synderesis and not to the mediaeval conscientia.

Literature: GASS, *Lehre vom Gewissen*

(1869), 216 ff.; and *Gesch. d. christl. Eth.*, § 122; ZIEGLER, *Gesch. d. christl. Eth.* (2nd ed.), chap. v; SIDGWICK, *Hist. of Eth.* (3rd ed.), 145; SIEBECK, in *Arch. f. Gesch. d. Philos.*, x. 521 ff. The derivation of the term is discussed in the *Athenaeum* (London) for 1877, i. 738, 798, iii. 16, 48. (W.R.S.)

Synechism [Gr. *συνέχης*, continuous, holding together, from *σύν* + *ἔχειν*, to hold]: not in use in the other languages. That tendency of philosophical thought which insists upon the idea of continuity as of prime importance in philosophy, and in particular, upon the necessity of hypotheses involving true continuity.

A true CONTINUUM (q.v.) is something whose possibilities of determination no multitude of individuals can exhaust. Thus, no collection of points placed upon a truly continuous line can fill the line so as to leave no room for others, although that collection had a point for every value towards which numbers endlessly continued into the decimal places could approximate; nor if it contained a point for every possible permutation of all such values. It would be in the general spirit of synechism to hold that time ought to be supposed truly continuous in that sense. The term was suggested and used by C. S. Peirce in the *Monist*, ii. 534 (July, 1892). Cf. PRAGMATISM, *passim*.

The general motive is to avoid the hypothesis that this or that is inexplicable. For the synechist maintains that the only possible justification for so much as entertaining a hypothesis, is that it affords an explanation of the phenomena. Now, to suppose a thing inexplicable is not only to fail to explain it, and so to make an unjustifiable hypothesis, but much worse—it is to set up a barrier across the road of science, and to forbid all attempt to understand the phenomenon.

To be sure, the synechist cannot deny that there is an element of the inexplicable and ultimate, because it is directly forced upon him; nor does he abstain from generalizing from this experience. True generality is, in fact, nothing but a rudimentary form of true continuity. Continuity is nothing but perfect generality of a law of relationship.

It would, therefore, be most contrary to his own principle for the synechist not to generalize from that which experience forces upon him, especially since it is only so far as facts can be generalized that they can be understood; and the very reality, in his way of looking at the matter, is nothing else than the way in

which facts must ultimately come to be understood. There would be a contradiction here, if this ultimacy were looked upon as something to be absolutely realized; but the synechist cannot consistently so regard it. Synechism is not an ultimate and absolute metaphysical doctrine; it is a regulative principle of logic, prescribing what sort of hypotheses are fit to be entertained and examined. The synechist, for example, would never be satisfied with the hypothesis that matter is composed of atoms, all spherical and exactly alike. If this is the only hypothesis that the mathematicians are as yet in condition to handle, it may be supposed that it may have features of resemblance with the truth. But neither the eternity of the atoms nor their precise resemblance is, in the synechist's view, an element of the hypothesis that is even admissible hypothetically. For that would be to attempt to explain the phenomena by means of an absolute inexplicability. In like manner, it is not a hypothesis fit to be entertained that any given law is absolutely accurate. It is not, upon synechist principles, a question to be asked, whether the three angles of a triangle amount precisely to two right angles, but only whether the sum is greater or less. So the synechist will not believe that some things are conscious and some unconscious, unless by consciousness be meant a certain grade of feeling. He will rather ask what are the circumstances which raise this grade; nor will he consider that a chemical formula for protoplasm would be a sufficient answer. In short, synechism amounts to the principle that inexplicabilities are not to be considered as possible explanations; that whatever is supposed to be ultimate is supposed to be inexplicable; that continuity is the absence of ultimate parts in that which is divisible; and that the form under which alone anything can be understood is the form of generality, which is the same thing as continuity. (C.S.P.)

Synergism (in theology) [Gr. *σύν* + *ἔργον*, work]: Ger. *Synergismus*; Fr. *synergisme*; Ital. *sinergismo*. The theory which has found many forms of expression in the history of Christian doctrine, that in the regeneration of man there is a co-operation of the human will with the divine grace in such a way as to secure man's free initiative and responsibility for his own salvation.

For a special sense see MONERGISM and the controversy which it involves.

Literature: see MONERGISM, PELAGIANISM, and JANSENISM. (A.T.O.)

Synergy: Ger. *Synergie*; Fr. *synergie*; Ital. *sinergia*. The union of partial or lesser motor processes or movements in a whole, giving a larger process or movement.

The term is applied especially to the motor functions of the brain, which unite in innervating a group of muscles; but it is also sometimes used for the muscles themselves, which are thus correlated in a single function or group of functions.

The theory which holds that mental synthesis and unity are due to the union of motor processes has been called the synergy theory (see James, *Psychol. Rev.*, ii, March, 1895, 105 ff.). (J.M.B.)

Synkatathesis [Gr. *συνκατάθεσις*, acceptance]. A Stoic term signifying the assent to or endorsement of a presentation as true.

The theory was very near to the modern view of judgment, which makes it an act of accepting or endorsing a presentation. See Eisler, *Wörterb. d. philos. Begriffe*, 'Beifall,' 'Synkatathesis,' for citations. (J.M.B.)

Synopsis: see SYNAESTHESIA ('Synopsis').

Syntechnic: see MIMICRY (in biology), CONVERGENCE (in biology), and cf. RESEMBLANCE (table).

Synthesis [Gr. *σύν + τίθεσθαι*, to set]: Ger. *Synthese*; Fr. *synthèse*; Ital. *sintesi*. The method, process, and function of putting things together, with the results; the opposite of analysis. See the various topics SYNTHESIS, and SYNTHETIC. (J.M.B.)

In education: synthesis applies to the subject-matter itself, as in chemistry, or to the logical processes involved, or more generally and vaguely to the chief direction of the mental activity. Thus, in illustration of the last, Ziller called the presentation of new matter in a lesson a 'synthetic' step, since the mind in apperceiving unites the new to the old; it 'synthesizes' present and former experiences. For similar reasons he called preparation an 'analytic' step, since the contents of the child's mind are analysed so that the ideas most needful for appreciating the new lesson shall be in the foreground of consciousness. See ANALYSIS, PREPARATION, PRESENTATION, FORMAL STEPS, and METHOD (in education).

Literature: BAIN, *Educ. as a Science*, 129-31; HERBERT, *Sci. of Educ.* (trans. by Felkin), 154-69; ROSENKRANZ, *Philos. of Educ.*, 101-6. (C.De G.)

Synthesis (chemical): see CHEMICAL SYNTHESIS.

Synthesis (mental or psychic): Ger. *psy-*

chische Synthese; Fr. *synthèse mentale* (or *psychique*); Ital. *sintesi mentale* (or *psichica*). (1) A mental combination in which the composing elements are not separately distinguishable; opposed to INTEGRATION (q.v., in psychology, 1).

The idea of synthesis has assumed great importance in view of the growing tendency to substitute some such principle for the law of association of ideas in many cases in which the latter has proved inadequate. Synthesis views take many forms, as in the theories of APPERCEPTION, ASSIMILATION, SYNERGY, and MENTAL ACTIVITY (see those terms). (J.M.B., G.F.S.)

(2) That unification or combination of the contents of presentation whereby they become qualifications of the same objective whole. Cf. INTEGRATION (in psychology, 2).

Thus the correlation of the data of different senses in the perception of a single material thing is a synthesis (1). Similarly, the comparison of different colour sensations so as to form a single qualitative series is a synthesis (2) at a higher level. At a yet higher level, we have the synthesis which Newton effected by his discovery of the law of gravitation.

(G.F.S., J.M.B.)

Synthesis (of Apprehension, &c., Kant): see APPREHENSION, ad fin. Kant distinguishes between 'mathematical' and 'dynamical' synthesis (*Critique of Pure Reason*). (J.M.B.)

Synthetic (-al): Ger. *synthetisch*; Fr. *synthétique*; Ital. *sintetico*. Having or producing the unity of a SYNTHESIS (q.v.).

Synthetic (-al) argument, inference, reasoning, &c. An argument whose conclusion expresses a fact the being of which is given in the being of the premises, so that the conclusion could not be false as long as the premise is true, is analytical; any other mode of argument is synthetical.

A synthetical argument may be a fallacy. In that case, it may be so absurd as not to be an argument in any other sense than that it professes to be so. But if it is an argument (as commonly happens) the real argument is either inductive or presumptive in its nature, these being the two types of synthetic argumentation.

Synthetic judgment: see ANALYTIC AND SYNTHETIC JUDGMENT, KANT'S TERMINOLOGY (Glossary, 'synthetische Urtheile'), HEGEL'S TERMINOLOGY (Dialectic, III, IV), SYNTHETIC PHILOSOPHY, and SYNTHESIS (different topics).

Synthetic method (in logic). What is commonly, very confusedly, meant by a synthetic method is a progressive deductive method,

more or less of the nature of reasoning in *Barbara*.

The confusion between analysis and synthesis is so great (cf. ANALYTIC AND SYNTHETIC JUDGMENT), and the distinction is founded upon such false views of logic, that it is perhaps best to abandon the words altogether in logic.

(C.S.P.)

Synthetic Philosophy (the): Ger. *die synthetische Philosophie*; Fr. *la philosophie synthétique*; Ital. *la filosofia sintetica*. The title of the series of treatises by Herbert Spencer, in which his philosophical system is built up as a 'unification of knowledge' drawn from various sciences. See the topics cited under SPENCERIANISM.

(J.M.B.)

System [Gr. *σύν* + *σῆναι*, to be set up, to stand up]: Ger. *System*; Fr. *système*; Ital. *sistema*. The term system is employed to designate a whole from the standpoint of the methodic connection and arrangement of its constituent members.

It differs from such terms as aggregate, collection, and inventory, in expressly connoting the orderly inherent bonds which bind together, from the standpoint of rational apprehension and explanation, the parts of the whole. It differs from such terms as organism, totality, and whole, in expressly connoting that it is from the standpoint of *thought*, of mental *method*, that the parts are interdependent. It differs, however, from 'classification' in implying that the mental method has been successfully applied to, and as it were worked over into, the facts; it does not remain outside of them as a merely mental scheme. A system arises whenever a particular plan, a working hypothesis, or scientific method has been so consistently, extensively, and deductively applied to the interpretation and arrangement of a body of facts as to give them internal intellectual coherence and unity, and obvious external detachment or distinction from other facts. This meaning

will be found to apply to such apparently diverse uses as the solar system, the post-office system, the system of Platonic philosophy, the system of Shakespearian dramas. The term is more nearly allied to 'organization' than to any of its congeners, all of which agree with it in connoting some kind of whole made up of parts. Cf. AGGREGATE, CLASSIFICATION, COLLECTIVE, ORGANISM, UNIT, and WHOLE AND PARTS.

(J.D.)

System (in education). A term used by Herbart to designate the organization of knowledge into a system; hence a stage in method, namely, that of 'generalization.' See FORMAL STEPS, and METHOD (in education).

Literature: HERBART, *Sci. of Educ.* (Eng. trans.), 126; REIN, *Outline of Pedagogics* (Eng. trans.), 135.

(C.DE G.)

System (mental). The mental life considered as a progressive organization of parts or elements in a SYSTEM (q. v.). Cf. SYNTHESIS (mental), SELECTIVE THINKING, and SELECTION.

(J.M.B.)

Systematic Determination (of thought): see SELECTIVE THINKING, RELATIVE SUGGESTION, and SELECTION (in psychology).

Systematic Theology: Ger. *systematische Theologie*; Fr. *théologie systématique*; Ital. *teologia sistematica*. That department of general THEOLOGY (q. v.) which treats of the system of religious doctrine and its organization into a logically coherent discipline; more especially, the system of the doctrines of the Christian religion.

The whole body of theology is ordinarily treated in four divisions: exegetical, historical, systematic, and practical. Systematic theology is either dogmatic or speculative, and includes such topics as the following: (1) theology proper (doctrine of God); (2) anthropology; (3) christology; (4) pneumatology; (5) soteriology; (6) ecclesiology; (7) eschatology.

Literature: see THEOLOGY.

(A.T.O.)

T

TABES — TABOO

Tabes [Lat. *tabere*, to waste away]: Ger. *Tabes*; Fr. *tabes*; Ital. *tabe*. Usually equivalent to *tabes dorsalis*, a disease of the spinal cord, described under ATAXIA (locomotor), which constitutes its characteristic symptom. (J.J.)

Taboo [Polynesian *tabu*, marked thoroughly, sacred]: Ger. *Tabu*; Fr. *tabou*; Ital. *tabù*. A sacred or religious prohibition which was best developed in Polynesia, but which in various forms and stages may be traced elsewhere.

The prohibitions of taboo refer both to actions and words or names. The prohibition may be general or applicable to all of a class of articles, or particular as applicable to special individuals alone. It may be permanent or temporary, affect both men and women, or women alone. It may be created by command of a king, or priest, or other official, or it might receive its sanction from tradition and custom. A few miscellaneous illustrations may be cited. In Hawaii the flesh of hogs, fowls, turtle, &c., in the Marquesas Islands human flesh, was tabooed for women. In these islands the houses may be tabooed from the use of water in them; a path may be tabooed and no one walk in it; an island may be tabooed and no one visit it; all of which may last for a definite number of days, or be permanent. If the name of a king of Tahiti was the same as, or resembled, a common word, a new name was substituted; while instances of words which it was unlawful to pronounce are most common. In this way, by modifying the use of names and substituting one for the other, the taboo has had a linguistic influence. As taboos affecting special persons (termed taboos of privilege),

may be cited the fact that if in Tahiti the king or queen entered a house it became taboo; the ground they trod on became taboo, and they were frequently carried on men's shoulders to prevent this. Many taboos were of natural rather than conventional origin; thus the exclusion of persons who were ill, of mothers after child-birth, of those who had to do with the dead, or were engaged in warfare, had obvious utility and plausibility. The punishment for violation of the taboo was both civil and religious; the transgressor might lose all his property, or he might be entered by a spirit and succumb to disease. There were elaborate ceremonies for removing the taboo.

Examples of taboo in historical religions may be found among the Jews, Greeks, Romans, and in superstitions of to-day. Among the Jews, the vow of the Nazarite (Num. vi. 1-21), some of the observances of the Sabbath (Exod. xxxv. 2, 3; xvi. 23, 29), the restrictions as to what was cleanly in man and beast, the avoidance of the sacred name of God; among the Greeks, the sacredness of certain animals and persons; among the Romans, the *flamen dialis*, the sacred priest who was forbidden to touch a horse, to look at an army, to touch or name a goat or dog, to walk under an ivy, &c.

The origin of the taboo is to be looked for in the animistic conceptions of primitive religion, while in its later developments it acquires a civil significance, and thereby aids the conception of property rights and marriage ties. In its earliest stages it is a general religious prohibition which develops into the prohibition of the unclean on the one side, and of the sacred on the other. On the

taboo 'were grafted the golden fruits of law and morality, while the parent stem dwindled into the sour crabs and empty husks of popular superstition' (Frazer).

Literature: FRAZER, art. Taboo, in *Encyc. Brit.* (9th ed.), from which the above illustrations are derived, and the fuller literature there cited; JEVONS, *Introd. to the Hist. of Religion* (1896). (J.J.)

Tabula rasa [Lat. *tabula*, tablet, *rasa*, empty]: used also in the other languages. The waxed tablet used by the Romans for writing purposes; used metaphorically to characterize the soul prior to sense-experience; employed to denote the theory of the empiricists, according to which all knowledge is imprinted by objects on a passive blank mind.

Plato used the metaphor of a waxed tablet, *κήρινον ἐκμαγείον* (*Theaet.*, 191), in discussing images of memory. Aristotle (*De Anima*, iii. 4) used a metaphor of a piece of writing paper to express the relation of potential to actual reason. This was erroneously used (as by Leibnitz) to make him the author of the *tabula rasa* theory. This was really first stated by the Stoics. Descartes used the phrase, but only ironically and incidentally. Leibnitz, in criticizing Locke's *Essay upon Human Understanding*, uses the phrase continually and technically, and from him it gained general currency as a summary view of the empirical theory (*New Essays*, Introduction). Locke himself does not use the phrase, though he speaks of the mind as a piece of white paper (loc. cit., Bk. II. chap. i. § 2), and employs constantly the metaphor of 'imprinting' sensations upon the mind. (J.D.)

Tachygenesis. See REGRESSION.

Tactile Illusions: see ILLUSIONS OF MOTION AND MOVEMENT, I.

Tactile or Tactual Sensation: see TOUCH SENSATION.

Taine, Hippolyte Adolphe. (1828-93.) Born at Vouziers, Ardennes, France, he was educated at the Collège Bourbon and the École Normale de Paris. Became a teacher, but soon abandoned the profession, devoting his attention to literature. In 1864 he became professor of aesthetics at the School of Fine Arts, Paris, and member of the Academy, 1878. He made contributions to empirical psychology in his book *L'Intelligence*.

Talbot-Plateau Law: Ger. *Talbot-Plateau'sches Gesetz*; Fr. *loi de Talbot-Plateau*; Ital. *legge di Talbot-Plateau*. If the rate of rotation of a disk bearing alternate sectors of different brightness or colour be sufficiently

great to produce a uniform sensation, that sensation is the same as what would be felt if all the light reflected from the several sectors were evenly distributed over the whole disk.

The departures from this law have always been found to fall within the mean error of observations, but when that error was from 5 per cent. to 8 per cent., the law could not be said to have been absolutely confirmed. Lummer and Brodhun have now, however, reduced this mean error to 2 per cent., and they find the departures to fall well within that limit, hence the law may be considered to be rigorously established. A disk with alternate sectors cut out, if interposed in the path of a beam of light, forms a means of diminishing its intensity by a measured amount; it is the best means that we have, since it is exact, it is easily combined with any apparatus, can be introduced anywhere in the course of the light-rays, does not change the character of the light, so that it is not necessary to attend to conditions of polarization nor of greater or less homogeneity (as in changing the width of a slit), and diminishes all light-rays equally and in accordance with a simple law. For sectors of less than 25° in breadth, however, diffraction from the edges interferes with correct results. Lummer and Brodhun have devised a very exact apparatus by which the size of the sectors can be continuously varied during rotation. This sectorized disk (Episkotister) was first used for photometric purposes by Aubert.

The Talbot-Plateau law is probably a particular case of the general chemical law of the action of light: if light of intensity a , acting during the time t , produces a chemical action

of intensity i , then light of intensity $\frac{a}{n}$, acting

during the time nt , produces the same chemical action i . (C.L.F.)

Talmud [Lat. *Talmud*, Chal. *talmud*, instruction, scholar]: Ger. *Talmud*; Fr. *Talmud*; Ital. *Talmud*. The book which contains the Jewish traditions as distinguished from their original Scriptures. It embraces (1) the original traditions ascribed to Moses, and (2) the commentaries and glosses of the later Jewish rabbins.

The Talmud is divided into two parts, the Mishna and the Gemara; the former containing the original traditions, the latter commentaries and glosses on these. The Gemara, to which the name Talmud is sometimes exclusively applied, is divided into two parts, the Jerusalemistic and the Babylonian, the

latter of which is much larger and of greater authority among the Jews than the former.

Literature: see articles in Schaff-Herzog's and McClintock and Strong's Cyclopedias; J. McCaul, *Old Paths* (1846); LOWE, *The Mishna*, on which the Palestinian Talmud rests (1882); LEVY, *Wörterbuch* (1875). (A.T.O.)

Tambour (of Marey): see LABORATORY AND APPARATUS, II (general).

Taoism: see ORIENTAL PHILOSOPHY (China).

Tariff: see PROTECTION.

Taste: see TASTE SENSATIONS.

Taste (aesthetic) [Lat. *tacare*, to touch sharply]: Ger. *Geschmack*; Fr. *goût*; Ital. *gusto*. The faculty of critical and appreciatory discernment of, and judgment upon, objects of aesthetic experience.

Often used as synonymous with 'good taste.' Employed also in an objective way, e.g. a building in good taste.

Taste has been generally recognized by aestheticians as involving at least two distinguishable elements: (1) native sensibility and delicacy of feeling—what may be called aesthetic temperament; (2) culture of the aesthetic judgment by actual exercise and discipline. Such discipline leads to the developed taste of the connoisseur. Taste is in the aesthetic life essentially what character is in the moral life. The question whether there can be any universal standard of taste has been much discussed. Writers of the associationist school (e.g. Jeffrey) have generally denied any real universality for such a standard, because of the multifold nature of the sources of beauty. Hume falls back on the consensus of cultivated opinion. Grant Allen, under biological influences, admits only such consensus as springs from similarity of nervous organization. Writers under idealistic influences have ordinarily defended a contrary view, because of the asserted universality of beauty (e.g. Lotze).

Literature: BURKE, *The Sublime and Beautiful* (2nd. ed. 1757); BEGG, *The Devel. of Taste* (1887); FECHNER, *Vorschule d. Aesth.* (1876). (J.R.A.)

Taste (physiology of). Action of soluble substances within the mouth, producing TASTE SENSATIONS (q. v.).

The terminal organ for taste sensations is the taste-bud, a group of modified epithelial cells among which ramify the end-brushes of the taste-nerves. These are, for the posterior third of the tongue, the ixth or glossopharyngeal, and for the anterior two-thirds of the

tongue, the lingual branch of the vth and, to some extent, the chorda tympani. The evidence indicates (Oehrwall) that each primary taste sensation is specific for a particular nerve-fibre.

Literature: TUCKERMAN, in Howell and Kastle's *Studies from the Biol. Lab. of Johns Hopkins Univ.* (1887), iv. 13; OEHRWALL, *Skand. Arch. f. Physiol.* (1890), ii. 1. (C.F.H.)

Taste (or **Gustatory**) **Sensations** (or simply tastes): Ger. *Geschmacksempfindungen*; Fr. *sensations de goût* (or *gustatives*), *saveurs*; Ital. *sensazioni gustative*, *sapori*. The sensations aroused by stimulation of the end-organs of taste. Cf. TASTE (physiology of).

There are four gustatory qualities or fundamental tastes: sweet, bitter, acid, salt. Phenomena of contrast, complementarism, and mixture have recently been observed among these qualities. Taste is hardly ever dissociated, in actual life, from smell; and many perceptions are consequently accredited to taste which are in reality olfactory in composition. Tastes are reproduced in kind with relative difficulty, and play but a small part in the higher mental life.

Literature: VON VINTSCHGAU, Hermann's *Handb. d. Physiol.*, iii. 2; WUNDT, *Physiol. Psychol.* (4th ed.), i. 438; KIESOW, *Philos. Stud.*, x, xii; SANFORD, *Course in Exper. Psychol.*, expts. 52-6; E. GLEY, art. *Gustation*, in *Dict. encyc. des Sci. méd. de Déchambre*; TITCHENER, *Lab. Manual* (1901), chap. iv. Modern literature may be said to begin with HORN, Ueber den Geschmackssinn des Menschen (1825); SUTZER's electrical experiment (1752)—the application of two different metals to the tongue; see *Hist. de l'Acad. des Sci. et Belles-Lettres de Berlin*, 1754, 356—also deserves mention. See also under TASTE (physiology of). (E.B.T.)

Tatian. Lived in the 2nd century A.D. An Assyrian or Syrian, he received a Greek education. Wandered about the Roman empire as a 'sophist,' being dissatisfied with all philosophies and religions; reached Rome 150 A.D. Embraced Christianity, and returned to Greece to teach and write on religious themes. Came again to Rome and became intimate with Justin, whom he greatly revered. Justin's death (166) left him alone, and the numerous Gnostic elements in his system exposed him to censure by the Roman Church, which he left about 172 A.D. He moved to Mesopotamia in the latter part of his life. The place and date of his death are unknown. See PATRISTIC PHILOSOPHY (4).

Tauler, Johann. (cir. 1290–1361.) Entered the Dominican Monastery at Strassburg, his birth-place, about 1318, where Meister Eckhart was professor of theology. Studied also in the Dominican College in Cologne, and possibly in St. James's College, Paris. Returned to Strassburg, whence the town council in 1339 banished the Dominicans. Went to Basel, where he became intimate with the 'Friends of God' (a mystical fellowship). Returned to Strassburg, probably 1346, and remained at his post when the Black Death visited that city.

Taurellus, Nicolaus. (1547–1606.) Born in Württemberg, his real name being probably Oechslein. Educated at Tübingen in theology, he subsequently studied medicine and taught on that subject at Basel. He was one of the first philosophers to oppose the traditional Aristotelian philosophy, aiming to bring philosophy into accord with the theology of the Reformation. See Smith, *Nicolaus Taurellus* (1860 and 1864).

Tautology [Gr. *ταὐτό*, the same, + *λόγος*, speech]: Ger. *Tautologie*; Fr. *tautologie*; Ital. *tautologia*. A useless repetition; a diallelon. A real diallelon destroys a definition, but a merely verbal one does not. (C.S.P.)

Taxation [Lat. *taxatio*, from *taxare*, to rate]: Ger. *Besteuerung*; Fr. *système d'impôts*; Ital. *tassazione*. A system of fixed and compulsory contribution levied to meet the general expenses of the government, whether national or local.

Taxes are distinguished from assessments and fees in being a contribution for general services instead of a more or less adequate return for special services. They are distinguished from fines and confiscations in being part of a regular system, publicly arranged as a means of meeting a deficit which the government account or budget would otherwise show.

There are two main theories of the equity of taxation: (1) equality of sacrifice; (2) minimum of aggregate sacrifice. If either theory were carried out to ideal perfection, the result would probably be very near the other. But in practice, and with the limitations of human character, the pursuit of the first aim results in conspicuous failure to reach either of the two; while the pursuit of the second tends to secure a fair measure of both results. (A.T.H.)

Taxonomic: see VARIATION (in biology), *passim*.

Taxonomy [Gr. *τάξις*, orderly arrange-

ment, + *νόμος*, a law]: Ger. *Taxonomie*; Fr. *taxonomie*; Ital. *tassonomia*. The laws and principles of the classifying of natural objects; that department of science which treats of classification. See CLASSIFICATION (in biology). (C.S.M.)

Tegmentum [Lat. *tegumentum* or *tegumentum*, a cover]: Ger. (1) *Haut*, (2) *Haubenfeld*; Fr. (1) *tégument*, (2) *étage supérieur du pédoncule*; Ital. (1) *integumento*; (2) *piano superiore*. (1) The outer covering of bodies; the skin. See CUTANEOUS SENSATION, *passim*.

(2) In neurology: the dorsal portion of the cerebral peduncles or covering of the crura cerebri. (C.F.H.)

Teleogony [Gr. *τέλος*, result, + *γένος*, production]: Ger. *Telegonie*; Fr. *télégonie*; Ital. *telegonia*. The supposed effect, on the progeny, of the previous crossing of the female parent with another male, shown by the transmission of certain characters of the first male to the offspring of the second.

Teleogony is popularly believed in, and called 'infection of the germ.' No convincing evidence has yet been discovered in favour of this alleged transmission. On the other hand, it must be owned that the known cases of XENIA (q.v.) in plants give some support to the view that the body of the female parent may be in some way affected by the sperm of the male, and it is conceivable that the development of the germ-cells might thus be influenced. [Recent experiments of Ewart, 'President's address,' Sect. Zool., Brit. Ass., *Nature*, Sept. 12, 1901, are entirely negation.—J.M.B.]

Literature: CH. DARWIN, *Animals and Plants under Domestication*; A. WEISMANN, *The Germ-Plasm* (1893); J. C. EWART, *The Penyuik Exper.* (1899); and as cited above. (E.S.G.)

Teleological Argument [Gr. *τέλος*, an end]: Ger. *teleologischer Beweis*; Fr. *argument téléologique*; Ital. *argomento teleologico*. That theistic argument which proceeds on the principle of finality and which reasons from the rational constitution of the world to the necessity that it should be grounded in a purposive intelligence. It is also called the 'design argument.' See TELEOLOGY, and cf. THEISM and (final) CAUSE.

The germ of teleology was involved in Anaxagoras' assertion that *νοῦς* or reason is the prius of the world. The thought was developed by Socrates in a somewhat empirical fashion. It was more speculatively treated by Plato under the idea of the good, while

Aristotle's practical identification of efficacy and finality renders his reasoning both cosmological and teleological. In modern times the English thinkers of the 17th and 18th centuries develop the argument on its empirical side, which calls forth the criticism of Hume and Kant. The Kantian criticism marks an epoch in the history of the argument, forcing it to become speculatively more profound, while on the empirical side it has been influenced by the doctrine of evolution, which has forced it to enter on a new and, in many respects, more fruitful phase.

Literature: see THEISM; HUME, Dialogues on Nat. Religion; KANT, Critique of Pure Reason; STERLING, Philos. and Theol.; FLINT, Theism and Anti-Theistic Theories; PHYSICUS, Candid Exam. of Theism. (A.T.O.)

Teleology: Ger. *Teleologie*; Fr. *téléologie*; Ital. *teleologia*. The word teleology covers the whole range of inquiry supposed to have a bearing on the doctrine that things exist because they ought, or for some purpose. Thus (a) the word properly denotes that branch of philosophical study which deals with 'ends' or 'final causes' as real principles of explanation; (b) it is perhaps more commonly used to denote the theory that everything has a final cause; and (c) it is also used to denote that property of things which consists in their relation to final causes. Further definition, then, must chiefly consist in the definition of 'end' or 'final cause.'

'End,' in the sense in which it defines teleology, must mean (1) something which is good in itself, and not merely as a means. Where 'end' means nothing but this, it may be conveniently distinguished by the name 'ethical end.' Teleology, then, can only be spoken of where ethical ends are supposed to be real principles of explanation. But by this supposition is meant (2) the doctrine that some things exist, because either they themselves or other things, to which they are means, are good. If, therefore, a good thing or ethical end is merely a cause in the proper sense of the word (see CAUSE), it is not said to be a final cause. For (3) the production of the effect is not then said to be due to the goodness of the ethical end, but to the prior existence of the good qualities which it possesses. It is only where a thing is supposed to produce an effect *because it is good* that it is said to be the final cause of that effect; and only so can the explanation of the effect by reference to it be said to be teleological. And further (4), where a good

thing is a cause merely in the ordinary sense, its effects often neither resemble it themselves nor are means to the existence of other effects resembling it, even in respect of goodness. But the effect of a final cause is always supposed to be either some good thing resembling it, or a means to the existence of some such good thing. These four conditions, then, namely, that the 'end' referred to must be (1) an ethical end, (2) a cause of the existence of something, (3) a cause in virtue of its goodness, (4) a cause of effects resembling it, constitute the indispensable minimum of meaning with which the word 'teleology' can properly be used.

But since conditions (3) and (4) can most easily be supposed to be fulfilled, where the ethical end is the object of some existing desire, we get a second notion, which is commonly included in the notion of teleology—the notion of what may be conveniently called a 'psychological end.' A 'psychological end' denotes any object which is desired, i.e. an object of which an existent mind is in some way aware, or of which the idea is present to it, and causes desire. Such an object may be something which already exists, but is not necessarily so; and even where an existent object is spoken of as an end in the psychological sense, it would generally be admitted on reflection that this use of the term is improper, and that the true 'end' is some effect of the object in question on something else—an effect which does not already exist. E.g. though a fruit which actually hangs on the tree may be a real object of desire, and may be spoken of as a psychological end, it would be generally admitted that the real end, in this case, is some kind of possession of the fruit—a possession which is not actual at the moment of desire, and the existence of which will commonly cause that particular desire to cease. [This distinction is sometimes characterized by the phrases 'world of fact' and 'world of desire.'—J.M.B.]

Teleology, then, commonly includes in its notion of 'end,' not only the 'ethical,' but also the 'psychological' end. Its 'final cause' generally means a good thing, which does not already exist but is already desired. It is only where an ethical end is thus also an object of desire, that its goodness, and not merely its good qualities or the end itself, can be easily supposed to produce effects at all, and that these effects can be supposed to resemble it. We are indeed commonly said sometimes to desire a thing 'because of its

goodness,' and it is a partial analysis of this popular conception which has led to the philosophical doctrine of final causes—that the goodness of things causes desire for them, and hence also causes that realization of them, which is effected by desire. The analysis is, however, only partial, since it has two defects. (1) It has always failed to distinguish between the goodness of a thing and the thing itself, or those qualities of it which are good. Thus, whereas the thing itself is commonly called the 'end' or 'final cause,' it is yet supposed that its effects are produced only because it is good, i.e. that its goodness is the cause of those effects. (2) It also fails to distinguish the object of desire from the idea of that object, which idea actually exists in the mind at the moment of desire, and may be said either to constitute a part of the complex fact called 'a desire,' or to be a cause of that desire. This idea is certainly part cause of the effects which desire brings about, and it is chiefly because it is not distinguished from its object that a 'psychological end' was ever supposed to be a cause at all, and the notion of 'final cause' ever conceived. Thus the idea itself is often spoken of as if it were the psychological end or final cause; and, even where the object of the idea is meant, that object is credited with the efficiency which belongs to the idea—an ascription which could only be defended on the ground of the philosophical theory, now generally given up, that the object of an idea is the cause of that idea's existence, and hence also of its effects.

Thus, where the 'end,' to which teleology refers us as a cause of existence, is supposed to be not only an 'ethical' but also a 'psychological' end, the word is commonly used as if it combined by definition the characters which belong (a) to a good object of desire, (b) to the goodness of that object, (c) to the idea of it, (d) to the idea of its goodness. Two further meanings are added to these when, as is often the case, the psychological end is held to be a sufficient mark of the 'end' of teleology; for we then get (e) object of desire, (f) idea of such object, as characteristics of a final cause from which the other four may be inferred. Since, however, it is difficult to maintain that every object of desire is *ipso facto* a good object, various methods are commonly adopted for reconciling meanings (e) and (f) with the first four. One common method is to say that the object of desire is always something which the person desiring it thinks to be good,

even if it is not really so. This method gives us four more meanings of final cause, all of which are often confused with one another and with the first six: (g) what is thought to be good, (h) its supposed goodness, (i) the idea of it, (j) the idea of its goodness. Another method of maintaining the identity of psychological and ethical ends is to say that all desire is directed to what is good, if not actually, at least 'fundamentally,' or 'really,' or 'by nature,' or 'in general.' This method again gives four new meanings to the 'end' of teleology, for each phrase used; and these four are also commonly confounded both with one another and with our first six. They are (k) the object of a 'fundamental' desire, (l) the goodness of that object, (m) the idea of it, (n) the idea of its goodness. We thus get fourteen possible ways of defining the 'end' which teleology declares to be a cause, each of which is emphasized by different philosophers or by the same philosopher, at different times, according as each belongs obviously to some object of which it is desired also to assert any of the other meanings.

The 'teleological' explanation of a thing, then, most usually denotes a discussion of it in which any or all of the fourteen notions above enumerated are confused with one another, provided only that (a) and (b) are among the number, and that the object, to which any one of them is applied, is supposed to be a cause of effects resembling itself. In this way the four minimum conditions for a proper application of the word 'teleology' are fulfilled, and at the same time a much fuller meaning is given to the term.

Attempts might be made to eliminate some of these sources of ambiguity and to give a clear and consistent meaning to 'teleology' as follows:—

(1) The supposition that, in order to produce its effects, an 'ethical end' must be also a 'psychological end' might be rigorously excluded. An 'ethical end,' as such, might be arbitrarily assumed to be the cause of everything resembling it; but, since it is eternally what it is, it would have to be supposed that it produced its effects at all times equally, and hence it could not be used in explanation of any differences between one state of the world and another, and the hypothesis might not admit the possibility of progress. It would also have to be arbitrarily decided whether (a), the ethical end itself, or (b), its goodness, was to be regarded as final cause; and the former alternative

would leave no reason for ascribing causal powers to it rather than to what is bad.

(2) Final cause might be defined as 'good psychological end,' and the 'idea' of such an end might be definitely excluded from the term. This definition would suffer from the same arbitrariness as the former, both in the ascription of causal powers to such an entity at all, and in the limitation of these powers to *good* objects of desire. It would further be impossible to regard such a final cause as sole cause of its effects; since, being defined as an object of desire, it could only be supposed to act when it also happened to be desired, i.e. the existence of a desire would be a necessary condition for the existence of its effects. It would only be this desire, and not the final cause itself, which could account for progress.

(3) The term 'final cause' might be definitely limited to the *idea* of good objects. It would then become obvious that a final cause denoted only one particular class of things which are causes in the ordinary sense, and not a different kind of cause. But, since good and bad ideas act in the same manner, the adoption of a particular name for the causation of the former only would be perfectly useless; whereas, on the other hand, causation by ideas, whether good, bad, or indifferent, is a process sufficiently different from other cases of efficient causation to be usefully denoted by a special name. Hence—

(4) The phrase 'teleological explanation' might be usefully employed, as modern psychology tends to employ it, to cover all cases where desire is assigned as a cause. But it would have then to be understood that 'final cause' denoted only one class of objects which are efficient causes; and that the historical connection of the term with 'ethical ends' was utterly abandoned.

Since Kant, the word 'teleology' has been frequently connected with a theory in which the word 'end' seems to be used in an even looser sense than any of the above. In all the above senses 'ends' and 'means' were distinguished, in that the 'means' denoted anything which was an efficient cause of the existence of something resembling or approximating to the end, and which was itself supposed to be produced by the final causation of the end; and thus the means might be regarded as both cause and effect of the end. In the modern theory, there is little attempt to distinguish in what sense, if any, the end is cause of the means, and hence 'end' seems

mainly to denote any good effect, and 'means' the cause of that effect. At the same time, however, it is maintained that an end has to its means a closer relation than is constituted by the mere fact that it is an effect of the latter. This closer relation is said to be observable in living bodies, where it is stated that all the parts are both means and ends to one another, and also all means to the whole. And any whole of which the parts are supposed to bear this relation to itself and to one another is called an 'organic' or 'teleological' unity. In what precisely this relation consists is not exactly defined; but it may be noted: (1) That, in order thus to regard two parts of an organism as means to one another, it is necessary to extend the meaning of the word 'means,' from a cause prior in time to its effect, to anything of which the existence is supposed to be a necessary condition of the existence of something else, even though both exist simultaneously. (2) That the relation, over and above this 'mechanical' relation, which ends and means are supposed to bear to one another, seems to be conceived as one which will entitle you to identify the means with the end, saying that the existence of the end is not only necessary to the existence of the means, but that the latter would not be what it is unless the end existed. Thus a 'teleological' relation is supposed to be a relation which alters the things it relates, so that it is not they, but some two other things which are related. And 'end' would seem to be defined as denoting either that one of two such things which (a) is not altered by the relation, but gives the other a likeness to itself, (b) is the better of the two; or the whole formed by two things which have this relation, which whole is generally supposed to be better than either separately and than other things, owing to the mere fact that it is constituted by such a relation. Those who suppose the world to constitute such a whole, often speak of the property thus belonging to it as 'the immanent teleology of nature,' as opposed to the 'teleology of outward design,' wherein the means is merely an efficient cause of the existence of the end. Cf. *ORIGIN versus NATURE*, *passim*.

History. The Greeks and Romans had no word corresponding to teleology, though it is from the Greek word *τέλος*, 'end,' that the name is derived. For a history of 'final cause' see *CAUSE*. It is only necessary here to add: (1) that Anaxagoras gave an impulse to Plato's teleology by his doctrine that the orderliness

of the universe was caused by the purpose of *voûs* to produce it; (2) that Aristotle does at different times ascribe to his *τέλος* all the fourteen different meanings above enumerated, often using the term *φύσις* to denote the 'reality' as opposed to the mere existence of a desire; and that his ultimate final cause is regarded by him as something which exists from the beginning and causes all change in the universe by the desire of all things to approximate to it, an approximation which he perhaps thought was always equally realized. In modern philosophy the terms 'end' and 'teleology' have generally superseded 'final cause,' and hence a fuller history is appropriate here than was given under CAUSE.

The form in which teleology first makes a prominent appearance is in connection with theology. The Christian doctrine that many, if not all, events are caused by God's will as means to the future existence of perfection had persisted through the Middle Ages, along with the Aristotelian conception of final causes; and the two were explicitly combined by Leibnitz (see CAUSE). But the exclusive prominence given to mechanical causation by the scientific successes of the Renaissance extruded in general the Aristotelian conception, whereas it could be easily combined with the Christian doctrine. Teleology, then, was chiefly used to mean the doctrine that God's will set the machine of nature going, for the sake of the good and beautiful things which it produces, and especially for the present benefit and ultimate perfection of man. Kant was chiefly instrumental in dismissing from philosophy this conception of teleology, by maintaining that we could not argue from the existence of good things to the fact that they had been designed by any one. He held, however, that there was in things an element which could not be explained by mechanical causes alone—an element which he called 'adaptation to ends' (*Zweckmässigkeit*). This element he discovered in three chief instances: (1) in the beautiful, (2) in living organisms, (3) in the fact that the world is such that we can know it. In these cases he seems to have thought that certain things, which were necessary conditions to one another's existence and to the whole which they formed, might also be said to exist (in some undefined sense) for the sake of the harmonious result produced by their coexistence; and that the whole, which they composed, changed their nature, so that their existence, as having that nature, might be said to be caused by the existence of the

whole. He thus gave rise to the last sense of teleology above defined. At the same time it is to be noticed that in his *Ethics* he uses 'end' in all the Aristotelian senses, and that he maintains a close connection between the moral end and that of nature. 'Teleology' still continues to have the very wide and vague significance thus given to it, as something higher than, or even contradictory to, mechanism; but the connection of this conception with that of psychological activity is now more generally emphasized than it was by Kant. The marked progress of biological studies in this century has also tended to revive the conceptions of Aristotle; the word 'end' being used, even by writers who do not speak of teleology, to denote a good or useful effect of organic changes, and frequently with an implication that the changes occur for the sake of this effect. (G.E.M.)

A broad view of history discloses certain types of teleological theory: (1) the teleology of deism, the view that there is a mind outside of nature creating or directing nature with a view to certain ends. On this view nature, apart from such direction, is a mechanical system. (2) The teleology of immanent theism, which finds in nature itself, either in part or whole, a strain of intelligence. Nature realizes ends which are intelligent or good over and above, or in opposition to, the results in which a strictly mechanical system would issue. (3) The view that the universe can be understood only as itself being a form of intelligence or reason, of which the mechanical is a partial exhibition, but of which only its character as end-realizing is the complete meaning. Of these three views we may say: to the first, intelligence interferes with mechanism; to the second, it denies or transcends mechanism; to the third, it interprets and completes the system of which mechanism is a partial expression. These three views are illustrated in history, first, by the teleology of the design argument (Paley); second, by that of the ontological arguments (Lotze); and third, by that of the identity philosophy (Schelling) and the various forms of absolute idealism (Hegel).

The evolution of the conception, reflected in the shades of meaning of the term, is accordingly that of the philosophy of theism. A progressive reinterpretation of nature has taken place, in which the claims of monistic idealism have made themselves felt. The current definition of teleology is therefore that of a world theory which does not exclude

mechanism, but in some way includes and re-interprets it.

Moreover differences emerge in construing the nature of the intelligence, reason, or thought, which is found in nature: so we have VOLUNTARISM (q. v.), INTELLECTUALISM (q. v.), SPIRITUALISM (q. v.), each maintaining a form of teleology. The essential problem to them all is that of showing how mechanical principles as formulated by physical science may yet be the vehicle of the realization of ends. The sort of discussion which arises in this field—about the principles of science—is illustrated in the remarks on natural selection and teleology under HEREDITY (q. v.).

A distinction is made under AUTOTELIC (q. v.) between that term and 'heterotelic.' These terms may be used to characterize the forms of teleology distinguished immediately above: to the deist the world process is heterotelic; to the immanent theist it vibrates between the two according to his emphasis; to the thoroughgoing monistic idealist it is autotelic. This gives to the world process in an absolute sense a character which is attributed in a relative sense to various functions and processes (e.g. art-creation). The parts of such a whole as the world whole, may be heterotelic when considered with reference to the whole; that is, as contributing to an end implicit in a whole itself perhaps autotelic. Or the reverse may hold: functions themselves autotelic may nevertheless, by realizing their ends, come into relation to a whole which is capable only of a heterotelic construction (as, for example, acts of individual conation found, when taken in large numbers, to illustrate the law of probability). Cf. MORAL STATISTICS, and see HEREDITY. (J.M.B.)

Telepathy [Gr. *τῆλε*, at a distance, + *πάθειν*, to experience]: Ger. *Telepathie*; Fr. *télépathie*; Ital. *telepatia*. Communication between mind and mind otherwise than through the known channels of the senses.

The term—which was introduced by F. W. H. Myers in 1882, and which is used in the publications of the Society for Psychical Research and elsewhere—has sometimes been limited to such communication between persons at a considerable distance from one another, the word thought-transference being

reserved for such communication between persons in the same room; but in practice this limitation is found to be inconvenient, and telepathy is used to include both. The word *telaesthesia* was suggested by Myers at the same time to express perception otherwise than through the senses, but without reference to a second mind. The term *metapsychosis* has been suggested to designate mental stata especially of the percipient (see below) under telepathic conditions.

The existence of telepathy is not yet generally admitted by the scientific world, but it has been one of the main functions of the Society for Psychical Research—in this article hereafter called S.P.R.—to obtain and investigate evidence on the subject.

The evidence is of two kinds. There are, firstly, experimental cases, where one person—the 'agent'—tries deliberately to convey an idea or impression to another—the 'percipient'—who may, or may not, be endeavouring to receive a communication at the time; and secondly, spontaneous cases, where communication occurs unexpectedly and unsought by either of the persons concerned.

Spontaneous occurrences *prima facie* telepathic have from time to time been noted in all ages and countries; and, in connection with hypnosis, experimental transference of ideas and sensations apparently otherwise than by the senses has been occasionally recorded during more than a century by French, German, and English observers. But it is only recently that these phenomena have been systematically investigated or their possible importance as evidence of telepathy recognized; and it is to W. F. Barrett that credit is due for first drawing public attention to this in a paper read before the British Association for the Advancement of Science in 1876. Experimental results in telepathy have, during the last quarter of a century, been obtained by a number of observers, and range from the transference of sensations and ideas between persons in the same room, to the production by the agent of apparitions of himself to a percipient in another house.

The older observers in mesmerism had observed in some cases 'community of sensation' between the patient and his hypnotizer, the former appearing to taste what the latter put into his mouth, or to feel pricks or pinches inflicted on the latter. Malcolm Guthrie, of Liverpool, succeeded in obtaining the same results with percipients in a normal state—unhypnotized—and the experiments

have also been repeated, by Gurney, with hypnotized percipients (see *Proc. Soc. Psych. Res.*, ii. 3-5, 17-19, 205).

More numerous attempts have been made, and by a greater number of experimenters, to transfer visual images of colour or form—whether of numbers, of diagrams and simple drawings, of playing-cards, or of ordinary objects—looked at by the agents. Many examples will be found in the *Proc. S.P.R.* and in the *Proc. Amer. S.P.R.* We may specially refer as specimens to experiments by Sidgwick and others, vi. 128-70; Guthrie and others, ii. 24-42; Lodge, ii. 189-200; Dessoir iv. 111-26. And a considerable amount of success has attended these attempts, both with percipients in a hypnotic and those in a normal state.

On the whole hypnosis seems to be a favourable condition for percipience. Though in these experiments the agent has often adopted the plan of actually experiencing the sensation—e.g. looking at a number—there is little reason for supposing that this is important, or that it serves any purpose other than fixing the agent's attention. Indeed, when the thing to be transferred is a visual image, it often happens that the idea is correctly apprehended by the percipient with no exact perception of the form. On the other hand, nameless forms have been transferred, and in some cases the form of an object or of a drawing has been reproduced by the percipient without any perception of its meaning. Experiments have been made in the transference of subjects mentally pictured by the agent and developed as hallucinatory pictures by the hypnotized percipient, which show interesting variations in the way in which the percipient's mind works on the transmitted idea (*Proc. Soc. Psych. Res.*, viii. 552-77). Cf. similar experiments (not telepathic) with verbally suggested ideas (*Proc. Soc. Psych. Res.*, viii. 459-63).

Another type of experiment is for the agent mentally to suggest actions to the percipient. With this may be classed cases in which a transmitted idea emerges through table-tilting or automatic writing. A valuable series of experiments of this latter class was carried out by P. H. and Mrs. Newnham (*Proc. Soc. Psych. Res.*, iii. 6-23), in which Mr. Newnham wrote down questions unseen by Mrs. Newnham, whose hand automatically wrote relevant answers, the purport of which she was unaware till she read them. For experiments in telepathic impressions expressed

through table-tilting see especially a series conducted by Charles Richet (*Rev. Philos.*, Dec. 1884, and *Proc. Soc. Psych. Res.*, ii. 247 ff.). In these cases the telepathic impact appears to express itself in action before it reaches the normal consciousness of the percipient. It may similarly sometimes be made to reach his normal consciousness through a visual or auditory hallucination, as in the experiments above referred to.

A form of experiment of some theoretical interest is the production telepathically of local anaesthesia—the making of, say, a selected finger rigid and insensible by purely mental suggestion. Here we have a mental suggestion not only reaching the percipient subconsciously, but producing an effect which it is not within his power to produce by voluntary effort. An experiment of this kind requires of course a specially suggestible percipient, and arrangements must be made to prevent his receiving through his senses any hint as to the special finger to be operated on (see *Proc. Soc. Psych. Res.*, viii. 577 ff., and i. 257, ii. 201, iii. 453, v. 14). Analogous to this is the production of hypnotic sleep at a distance, as recorded by Gibert and Pierre Janet and other French experimenters (*Rev. Philos.*, Feb. and Apr. 1886, Sept. 1888; *Rev. d. l'Hypnot.*, Feb. 1888; also *Proc. Soc. Psych. Res.*, iv. 133, v. 43).

Finally, under the head of experimental telepathy must be mentioned a small number of successful attempts by the experimenters to cause apparitions of themselves to a friend in another house or room (see *Phantasms of the Living*, i. 103-9, lxxxi-iv; *Proc. Soc. Psych. Res.*, x. 270-7). These are of special interest on account of their analogy with cases of spontaneous telepathy to be mentioned presently.

In experimenting in telepathy the sources of error to be guarded against—apart, of course, from wilful deception—are of three kinds. First, the agent may unconsciously give indications by word, look, gesture, variations of breathing or of muscular pressure, &c., which may reach the percipient through his senses and be unconsciously interpreted by him. With hypnotized percipients especially, it is, moreover, necessary to take account of the possibility of hyperaesthesia or abnormal acuteness of the senses. Variations of muscular pressure are so difficult to guard against when agent and percipient are in contact, as in the so-called willing game, that it is seldom possible to attach importance to results

obtained under these circumstances. Apart from contact, the possibilities of indications through the senses in some kinds of experiments are very subtle, and require constant watchfulness and attention. Hansen and Lehmann, of Copenhagen, for instance, found that in experiments in transferring numbers they were liable, unless they directed their attention to avoiding it, to whisper the number thought of, so that the sound could, under suitable conditions, be heard by the percipient, and this although the agent's lips were closed and not visibly moving (*Philos. Stud.*, xi. 4). On this basis they criticized the conclusions drawn from the series of experiments in transferring numbers, published in the *Proc. Soc. Psych. Res.*, vi. 128 ff. Their results in guessing numbers intentionally whispered with closed lips were repeated and confirmed by H. Sidgwick; but their inference that this particular source of error vitiated the experiments referred to was shown to be ill founded (*Proc. Soc. Psych. Res.*, xii. 298-315; see also *Science*, May, 1899).

Secondly, in estimating results care must be taken to note how far habit or association or external suggestion may at any given time suggest the same idea independently to agent and percipient. For instance, most persons, when asked to name numbers at random, have a tendency to name some more often than others; so that, unless the agent avoids all selection, by some such device as drawing numbers out of a bag without seeing them, there is a danger that a coincidence of 'number-habit' between him and the percipient may produce a fictitious semblance of thought-transference (see paper on the 'Number-Habit' by C. S. Minot, *Proc. Amer. S.P.R.*, 86). The effect of 'diagram-habit' has also been investigated by Minot (*Proc. Amer. S.P.R.*, 302 ff.) and by G. Le M. Taylor (*Proc. S.P.R.*, vi. 398).

A third danger to be avoided is that of overestimating the resemblance between the impressions of the agent and of the percipient (see Hansen and Lehmann, loc. cit.). This cannot of course occur where the attempt is made to transfer an idea so definite as a playing-card or a number; but with less simple ideas, or with nameless forms, resemblance may be striking without being exact, and care must be taken not to allow bias to operate in estimating the degree of correspondence. In these latter experiments, too, the probability of success by chance in any

one experiment cannot usually be calculated—an important consideration, since in a series of telepathic experiments it is seldom found that even the majority of the percipient's impressions are correct. Thus in the whole series of 644 trials with numbers of two digits to which reference has already been made (*Proc. Soc. Psych. Res.*, vi. 128), only 117 were completely successful. As, however, the probability of a single guess being right by chance was known to be 1 in 81, it can be shown that the result obtained proves a causal connection between the number drawn and the percipient's impression. Such arithmetical proof is not possible in the case of diagrams and simple drawings made at the moment—a form of experiment which, however, for other reasons offers considerable advantage.

Turning now to spontaneous telepathy, instances of what there is *prima facie* good ground to regard as such may be found corresponding to most of the forms of experimental telepathy already mentioned. Trivial experiences, however, such as those of which the bulk of the experimental evidence consists, can seldom afford strong evidence of telepathy when occurring unsought; and therefore, as regards spontaneous telepathy, the interest centres in cases where a striking subjective experience of an unusual kind—such as a sensory hallucination—corresponds in a marked way with some crisis in the life of the supposed agent. Such an occurrence is the seeing of an apparition of a friend at the time of his death. For a sensory, and especially a visual hallucination, such as the apparition of a friend in a part of space actually unoccupied by anything resembling a human being, is not a very common experience with persons in good health; most persons go through life without it, and with those who have an experience of this kind it is often unique. If it occurs, therefore, at the time of the death of that friend, the presumption of a causal connection between the two is *prima facie* strong; and the analogy of experiment, and especially of the occasional—though it must be admitted rare—production of an apparition of the agent as a result of an attempt to communicate telepathically, suggests that that causal connection is telepathic. It is convenient to distinguish hallucinations thus causally connected with an external event as 'veridical' or truth-telling. It must be remembered, however, that the great majority of hallucinations, even of those experienced by sane persons, are not veridical, so that the proof that appa-

rently veridical ones coincide with the external event otherwise than by accident depends on the proportion of their number to the whole number of apparitions being greater than can reasonably be explained by chance.

A discussion of apparitions from the point of view of telepathy, by Gurney, Myers, and Podmore, was published, under the name of *Phantasms of the Living*, in 1886. Further discussion and evidence will be found in the 'Report of the Census of Hallucinations' (*Proc. Soc. Psych. Res.*, x, 25 ff.), the authors of which conclude that the evidence strongly supports a telepathic explanation of the coincidences¹.

In discussing telepathy reference must be made to the alleged instances of the detailed perception of scenes, places, and events unknown in any normal manner to the percipient, but known to some human mind, though there is no agent either trying to transfer the impression or going through any special crisis. The evidence for this faculty, sometimes called 'clairvoyance' or *teleesthesia*, though inferior to that far more simple telepathy, is still sufficient to call for recognition.

The percipients in these cases have usually been in a hypnotic or similar trance state, though sometimes such visions occur through crystal vision or otherwise to persons fully awake. The scene described is sometimes within the knowledge of persons in the room, and sometimes, if telepathically learnt, could only be learnt from persons at a distance. The perception is sometimes of past scenes, sometimes of things existing or happening at the moment, and sometimes relates to intentions rather than facts. (See *Proc. S.P.R.* vii. 30-99, 199-220, 356-69, 370-3; viii. 405-11; also Andrew Lang, *The Making of Religion*, chap. v.)

The reasons for supposing that such knowledge is acquired telepathically rather than by direct perception of any kind unmediated by another mind, are: (1) that in some cases the mind of a person present is the most obvious source of information, e.g. when a scene is described in which a person present

took part the day before; and (2) that, if on other grounds we admit telepathy as a *vera causa*, we must obviously assume for it as wide a scope as possible before attributing other unknown powers to the human mind.

While briefly indicating some of the more important lines on which evidence for telepathy has been sought, little has so far been said as to the nature of the process or the conditions under which it may occur. As a matter of fact, but little progress has been made towards any theory or explanation. If the telepathic faculty exists at all, we should expect to find at least traces of it in most of us, and experiment has to some extent confirmed this (see Richet in *Rev. Philos.* for Dec., 1884, 'La Suggestion mentale et le Calcul des Probabilités'; also *Phantasms of the Living*, i. 33 ff.). But one thing that seems certain is that some persons are more capable than others of receiving or of transmitting ideas telepathically. There is, moreover, some reason for thinking that a good percipient is likely to be also a good agent.

Even with the best agents and percipients who have yet experimented, however, success cannot be depended on. One day almost every attempt to transmit an impression may succeed, and the next the percipients may either have no impressions at all or wholly incorrect ones. Even in consecutive periods of time and with no discoverable change of conditions success will vary. Under these circumstances it is of course difficult to draw theoretical conclusions of any value from failure under conditions intentionally varied. It is not surprising, therefore, that even so fundamental a question as whether the process is a physical or a purely mental one cannot be answered with certainty.

The possibility that telepathic transmission is effected by vibration in the ether has been more than once suggested, and notably by Sir William Crookes in his presidential address to the British Association for the Advancement of Science in 1898; and in support of this hypothesis may be urged the fact that in experiments, distance seems to increase the difficulty of transmission. But, on the other hand, the effect of distance has not been observed to vary according to any law; and—since part of the telepathic process is undoubtedly mental, and psychological causes, such as preconceived ideas, influence the results—it is quite possible that the difficulty introduced by distance may not be physical at all, but purely psychological. And we have

¹ The conclusions of the report were controverted by Edmund Parish in two brochures entitled *Über die Trugwahrnehmung und Zur Kritik des telepathischen Beweismaterials* (1894 and 1897), which were combined in an English translation published in the Contemporary Science Series under the name of *Hallucinations and Illusions*. A reply to Parish appeared in the form of a review in *Proc. Soc. Psych. Res.*, xiii. 589. [This work by Parish is considered one of the ablest negative criticisms of telepathy, especially as bringing out the psychological factors involved.—J.M.B.]

an argument against a physical explanation of telepathy in the spontaneous cases, since, so far as the evidence enables us to judge, it here operates independently of distance. An apparition of a dying friend is apparently as likely to occur when he is in the Antipodes as when he is in the next room. But the evidence is perhaps hardly sufficient to justify even a tentative generalization. Light could of course be thrown on the question if we could ascertain whether time is occupied in telepathic transmission, and, if so, measure it.

Even supposing, however, that the time occupied were appreciable, the difficulty of measuring it would seem almost insuperable, since we do not know how to ascertain which is the moment of the effective action of the agent, nor which is the moment of the telepathic receipt of the message by the percipient. The former may be indefinitely later than the first inception of the idea, and the latter may precede the emergence into consciousness, remaining latent for an unknown interval.

To sum up, there is a body of evidence of various kinds for the existence of telepathy which cannot be ignored; but, as yet, little has been done towards discovering the nature of the process or the conditions under which it occurs, and there is urgent need for further experiment and observation.

Telesius, Bernhardinus. (1508-88.) Educated at Rome. After 1538 he lived in Rome, devoting himself entirely to the study of natural science until about 1565, when he was called to Naples to teach. He is a forerunner of Bacon and the modern scientific era.

Temper: see TEMPERAMENT, and TERMINOLOGY, German, 'Gemüths.'

Temperament [Lat. *temperamentum*, pro-

portion, from *temperare*, to modify; trans. of Gr. *κράσις*], Ger. *Temperament*; Fr. *tempérament*; Ital. *temperamento*. Characteristic difference in the congenital constitution of individuals, manifested, e.g., by differences in their emotional susceptibilities, in the rapidity of their mental processes, in the fixity of their conations, &c. See INDIVIDUAL PSYCHOLOGY, and cf. VARIATIONAL PSYCHOLOGY. 'Temper' is used as equivalent to temperament, with especial stress upon emotional and volitional character. (J.J.-J.M.B.)

The traditional classification of temperaments is into the sanguine, melancholic, choleric, and phlegmatic. The sanguine and choleric are supposed to be subject to rapid alternation of interest. With the choleric, interest is intense while it lasts, whereas with the sanguine it is relatively feeble. The interest of the melancholic and of the phlegmatic is persistent when once it is aroused, though they are not easily excited. The interest of the melancholic is intense, whereas that of the phlegmatic is lacking in vividness.

Literature: HENLE, Anthropol. Vorträge, Heft 1, 118 f.; KANT, Anthropol.; GEORGE, Lehrb. d. Psychol., 136 ff.; WUNDT, Phys. Psychol. (4th ed.); RIBOT, Psychol. des Sentiments. Cf. INDIVIDUAL PSYCHOLOGY. (J.J.)

Temperance: Ger. *Mässigkeit*; Fr. *tempérance*; Ital. *temperanza*. Moderation and self-control in anything, but especially in indulgence in pleasures. (J.S.-J.M.B.)

Temperance, in the large sense of moderation or self-control (*σωφροσύνη*), was the characteristic Greek virtue. The product alike of political and religious conditions was a deep sense of the duty of obedience to law or observance of the limit, of the excellence of modesty (*αἰδώς*), and of the evil of insolence (*ἕβρις*). The Greek regard for rational order and for the grace of form is at the root of the matter. For Plato temperance is one of the four cardinal virtues, both in the state and in the individual. He describes it as a harmony or agreement between the higher and the lower parts—the governing and the governed in the state, the rational and the appetitive in the soul, resulting in the obedience of the lower to the higher. While Aristotle's specific virtue of temperance is still narrower in its range than Plato's, he may be said, in his doctrine of the 'mean,' to reduce all virtue to the habit of moderation or temperance in the large sense. Christianity reaffirmed the importance of this virtue, deepening and broad-

TEMPERATURE SENSATION — TEMPORAL SIGN

ening the Greek conception of it. The new emphasis given by Christianity to the negative element in temperance, through its principle 'die to live,' led to the exaggeration of temperance into abstinence, which is, in Aristotle's eyes, an extreme—that of defect—no less than excess. On the difference between Christian and Greek ideas of temperance cf. Green, *Proleg. to Ethics*, Bk. III. chap. v. §§ 261-78. (J.S.)

Temperature Sensation: Ger. *Temperaturempfindung*; Fr. *sensation de température* (or *thermique*); Ital. *sensazione termica* (or *della temperatura*). A sensation of heat or cold.

It is obtained by stimulation of the skin or certain parts of the mucous membrane that takes the place of the skin. These sensations present an analogy to the simple affective qualities of pleasantness and unpleasantness, in that they pass over into one another through a point of INDIFFERENCE (q. v.). Whether Weber's law holds for temperature intensities is still an open question.

Theories of the temperature sense are as yet very incomplete. We have: (1) the assimilation-dissimilation theory of Hering; (2) the adaptation theory of Wundt; (3) the specific energy theory of Goldscheider. It should be noted that an attempt has recently been made to distinguish between the qualities of 'hot' and 'warm.' Cf. TEMPERATURE SPOT.

Literature: WUNDT, *Physiol. Psychol.* (4th ed.), i. 385, 415; HERING, *Hermann's Handb. d. Physiol.*, iii. 2; SANFORD, *Course in Exper. Psychol.*, expts. 13-20, 25; GOLDSCHIEDER, *Du Bois-Reymond's Arch.* (1885), 340 ff.; and Pflüger's *Arch.* (1886); ALRUTZ, in *Mind*, N.S., vi, vii; TITCHENER, *Lab. Manual* (1901), chap. iii; VON FREY, *Ber. d. math.-phys. Cl. d. k. Sächs. Gesell. d. Wiss.* (March 4, 1895); BLIX, *Upsala Läkareförenings Förhandlingar* (1883); DONALDSON, *Mind*, O.S., x (1885); KIESOW, *Philos. Stud.*, xi (1885); CRAWFORD, *Psychol. Rev.*, v. (1898) 63 ff. Cf. CUTANEOUS SENSATION, and HAPTICS. (E.B.T.)

Temperature Spot: Ger. *Temperaturpunkt* (*Kältepunkt*, *Wärmepunkt*); Fr. *point de sensibilité thermique* (*point froid*, *point chaud*); Ital. *punto di sensibilità al freddo* (*al caldo*), *punti termici*. A spot of the skin, areal rather than punctual, evincing a peculiar sensibility to heat or cold. The PAIN SPOTS (q. v.) are, as a general rule, most thickly distributed; pressure spots less thickly; cold spots still less thickly; heat spots most sparsely. The functional stability of the tem-

perature spots has been questioned. [E.B.T. prefers the terms 'warm-spot' and 'warmth,' to 'heat-spot' and 'heat.'—J.M.B.] (E.B.T.)

Spatial discrimination is less acute by temperature spots than by pressure spots, and less by heat spots than by cold spots. (C.L.F.)

The use of 'spot' rather than 'point' would seem to be justified in view of the questioning of the theory of elementary nerve-elements each acting alone for a single 'point,' not only in this case (Crawford as cited under TEMPERATURE SENSATION), but also in the determination of SENSORY CIRCLES (q. v., Tawney). If points are finally determined within the spots, both terms may remain in use. (J.M.B.)

Literature: WUNDT, *Physiol. Psychol.* (4th ed.), i. 417 ff.; SINGER, *Psychol. Rev.*, iv. 256; and the literature cited under TEMPERATURE SENSATION. (E.B.T.)

Temporal: see TIME.

Temporal and Eternal [Lat. *temporalis et aeternalis*]: Ger. *zeitlich und ewig*; Fr. *temporel et éternel*; Ital. *temporale ed eterno*. Terms employed to distinguish that which belongs to the order of passing change from that which is unchangeable and enduring, and which is conceived to be more real than the temporal.

The instinct of religion is to seek and rest in the abiding and the immovable. The changeable and temporal aspect of things is a show-world, to use Royce's phrase, which has no reality. Eternal is a term which applies to that which transcends the whole perishable aspect of things, and is therefore applied to that ideal life which satisfies the deepest religious aspirations. (A.T.O.)

Temporal Sign: Ger. *Temporalzeichen* (Lipps); Fr. *signe temporal*; Ital. *segno temporale*. A term coined on the analogy of LOCAL SIGN (q. v.) to indicate the process or attributes of process which determine the temporal relations of ideas, whether to one another or to the subject.

According to Wundt, 'feelings of expectation are the qualitative, and sensations of movement the intensive temporal signs of a temporal idea. The idea itself must then be looked upon as a fusion of the two kinds of temporal signs with each other and with the objective sensations arranged in temporal form' (*Outlines of Psychol.*, Eng. trans. 1897, 156 f.). Cf. Lipps' memory-image theory (*Grundtatsachen des Seelenlebens*, 1883, chap. xxvi) and Münsterberg's theory of muscular strain sensations (*Beitr. z. exper. Psychol.*, ii. 1889, 13). (E.B.T.)

The theory of temporal signs is connected with that of 'genetic nativism' in the larger problem of the cognition of TIME (q. v.; cf. EXTENSION). The signs may not be temporal, but qualitative and intensive. The element of nativism comes in in the synthesis of these signs in the form of time with the arrangement of events in an order of succession. The problem of time-cognition has been developed by Ward (*Encyc. Brit.*, 9th ed., art. Psychology) under the figure of a cross section of consciousness represented by a circle with data of present and past experience (presentations and ideas) distributed in it. The time line passes through the centre at right angles to the plane of the circle. Assuming that the circle is without thickness (that is, that it cuts the line at a point), the problem of time-cognition and of temporal signs may be stated thus: how are the items at present in the circle distributed as before and after on the line which is at right angles to it? The theory of genetic nativism answers: only by some distinctive marks or signs attaching to these items respectively upon which consciousness proceeds in the construction of the time line: these marks are the temporal signs. If, however, we hold that the circle is not without thickness (in other words, that it is a segment itself occupying a time-period), then there is a time-datum, an attribute of 'temporality,' which takes the place of temporal signs, and by successive piecing out, end on end, builds up the time line. The essential of time cognition (i. e. before- and after-ness) is then given in this datum of temporality—what James calls 'the specious present.'

In either case past time is a construction by abstraction from concrete 'pieces' of duration, and future time is a similar construction.

Different temporal signs have been designated by various writers: relative intensity or vividness of presentation or idea (the most intense being nearest to the present); relative grouping of the items in the present, which is interpreted to reconstitute the order of original occurrence; movements of attention (variations in the attention process being signs of the temporal order of the items as originally attended to).

Literature: that of TIME (q. v., different topics). (J.M.B., G.F.S.)

Temporality: no foreign equivalents in use. Suggested to designate the original temporal datum, or time-extent; analogous to EXTENSITY (q. v.) considered as a datum of

space-extent: such a datum being, however, in each case in dispute. (J.M.B., G.F.S., C.L.F.)

Temptation [Lat. *tentare*, to try]: Ger. *Versuchung*; Fr. *tentation*; Ital. *tentazione*. Appetence towards that to which a lower, or away from that to which a higher, value is consciously assigned; applied also to the object of the lower appetence in either case. (J.M.B.)

Tendency [Lat. *tendere*, to stretch]: Ger. *Tendenz*; Fr. *tendance*; Ital. *tendenza*. The existence of a tendency is constituted by that state of a being which (1) will issue in a certain process on the removal of inhibiting or interfering conditions, positive or negative; and (2) will maintain its own positive nature in and through the new conditions.

An acorn may be crushed into a shapeless mass, or it may grow into an oak. But we do not speak of it as having a tendency to be crushed into a shapeless mass, whereas we do naturally regard it as having a tendency to grow into an oak. The reason is that we consider it as maintaining its distinctive acorn nature in becoming an oak, but not in being crushed.

The mental fact which we call CONATION (q. v., also on variations in the German equivalents) is a clear instance of tendency in the sense defined. In the process of attaining its end, it is 'realized' or 'fulfilled' instead of being destroyed or suppressed, and it always proceeds to the attainment of its end if, and so far as, other conditions permit. The term tendency may also be appropriately applied to the conative disposition or to dispositional INTEREST (q. v.); for these tend of themselves to issue in actual conations, and do so in the absence of interfering conditions. Cf. the very closely related concept POTENTIALITY.

Literature: LIPPS, *Grundtatsachen des Seelenlebens*; the literature of CONATION, and WILL. (G.F.S., J.M.B.)

Tendon Sensation: Ger. *Sehnenempfindung*; Fr. *sensation des tendons*; Ital. *sensazione tendinea*. In the perceptions of resistance, of lifted weight, &c., there is involved a sensation of strain, qualitatively distinct from the pressure sensations of skin, joint, and muscle, and from pain. There is an element in the sensation of strain which is probably furnished by the terminal organs of the sensory nerves which run to the tendons, and which is therefore called tendon sensation. Cf. STRAIN SENSATION.

On its intensive side, the tendon sensation has been found to obey Weber's law, thus resembling the sensation of pressure. Cf. **HAPTICS**, and **ORGANIC SENSATION**. (E.B.T.)

Literature: KÜLPE, *Outlines of Psychol.*, 142, 162; GOLDSCHIEDER, *Du Bois-Reymond's Arch.* (1889, 3 arts.); MÜLLER and SCHUMANN, *Pflüger's Arch.*, xlv; BEAUNIS, *Les Sensations internes*; CLAPARÈDE, *Le sens musculaire*. (E.B.T.-J.M.B.)

Tenet: see **DOGMA**.

Tennemann, Wilhelm Gottlieb. (1761-1819.) Born and educated at Erfurt, he became Privat-docent in 1788 at Jena, and lectured on the history of philosophy. He became assistant professor at Jena in 1798. From that time until 1819 he was engaged in writing his history of philosophy in eleven volumes. After 1804 he was professor of philosophy in Marburg, where he died.

Tense: see **CONJUGATION** (in grammar), and cf. **GRAMMAR**.

Tension (sensations of): see **STRAIN SENSATION**.

Tenure (of land) [Lat. *tenere*, to hold]: Ger. *Art der Lehnbarkeit*, (2) *Lehen*, *Erbbesitz*; Fr. *tenure*; Ital. *possesso della terra*. (1) The right of holding property in land.

(2) The kind of right by which property in land is held.

English tenures are based on the feudal system, under which each proprietor (tenant) held under a feudal superior to whom he owed some feudal service, the ultimate superior being the king. This has become so interwoven with their political constitution, that although the many ancient feudal tenures are now practically reduced to one—that of free and common socage—English courts still treat the heritable qualities of land as not subject to variation in favour of those claiming under foreign adoptions, legitimations, or marriages of a kind not permitted by English law. See Dicey, *Conflict of Laws*, Intro., 32, chap. xxii. Feudalism viewed all land as the fruit of conquest, and its owner as invested with the rights of a conqueror, as to jurisdiction as well as property. Roman law viewed it as acquired by virtue of a civil act of the state—a grant, passing property, but not any sovereignty or jurisdiction. 'At Rome, property was derived from political rights, rather than political rights from property' (Arnold, *Hist. of Rome*, i. 168). The English colonies in America were generally settled under charters specifying that the lands were to be held of the king, as the lord, in free and

common socage, as of some specified English manor. *Military tenure* required of the tenant military aids and services, uncertain as to the time of their performance, because dependent on military necessities. *Free socage tenure* required free, honourable, and certain aids or services, not of a military character, or in some cases fealty only; and *free and common socage tenure*, of the king, was a tenure by mere fealty. Colonial practice and legislation soon made land titles there, generally, *allodial*, i.e. an absolute fee simple estate of inheritance, not held of any superior (see Kent, *Commentaries on American Law*, iii. 509). Allodial tenure preceded feudalism on the continent of Europe, and was less absolutely superseded by it there than in England. The French Revolution turned France into a country of small proprietors in fee (see *Code Civil*, Liv. II. tit. ii). *Freehold tenure*: an estate held under no superior for a life or some uncertain period.

Kinship is the first basis of civil society, and when the nomad tribe settles down upon a fixed territory, the land becomes the bond of union, in place of the connection by blood. Land tenures are at first common, then individual. See Maine, *Ancient Law* (103), *Village Communities*, and the *Early Hist. of Inst.* (72, 188).

Literature: BLACKSTONE, *Commentaries*, ii. chaps. v, vi; LORIA, *Analisi della proprietà capitalistica*; *Systems of Land Tenure in Various Countries*, edited for the Cobden Club by J. W. PROBYN; the works cited above. (S.E.B.)

Teratology [Gr. *τέρας*, monster, + *λόγος*, science]: Ger. *Teratologie*; Fr. *tératologie*; Ital. *teratologia*. The science which treats of malformations or monsters.

Under this are included cases of particularly abnormal formations, such as supernumerary members, absence or deficiency of limbs, double monsters (Siamese twins), one creature with two heads, hermaphrodites, acephalic monsters, &c. On the mental side these are of interest as indicating the correlation of abnormal physical with abnormal mental conditions, and as illustrative of the effects of brain deficiency or peculiarity. They fall under **VARIATIONAL PSYCHOLOGY** (q. v.). In anthropology, mythology, and folk-lore, monsters have always been a subject of speculation and myth. See **MONSTER** (also for literature), and **SPORT**. (J.J.)

Term [Lat. *terminus*, trans. of Gr. *ὄρος*, literally a boundary; there is a Greek word

τέρμα, but it is not used in a logical sense]: Ger. *Terminus*; Fr. *terme*; Ital. *termine*. (1) One of the principal parts of a PROPOSITION (q.v.). If from the proposition 'Socrates is mortal' we strike out the separate indication of the subject we have '— is mortal'; and this ought to be regarded as a term. It is usually stated that 'mortal' is the term; but if there is any difference, it should rather be '— is mortal.'

In most languages no separate word 'is' is required to assert that 'Socrates is mortal'; and as long as Greek was the language of logic, in which an *is* may be inserted or may be omitted, little importance was attached to the *is*. But the Latin logicians of the 12th century began to regard this as essential, and thus made a distinction between 'is mortal' and 'mortal,' which relates to the peculiarities of a small class of languages. Thereafter logicians, and especially nominalists, began to regard terms no longer as parts of propositions, but as general names having an existence and meaning irrespective of any potential proposition. In most languages there appear not to be any such nouns, or very few. In Semitic languages, for example, common nouns are thought as parts of verbs, approaching the nature of participles, as most of them in fact are. It is, therefore, scarcely more true that they are mere names than that our words 'seeing' and 'dying' or 'moriturus' are names. There is in connection with them the idea of their being fragments of possible propositions; and so much so, that the mere adjunction of two of them makes a proposition.

If, however, we are to take *term* as meaning a word used as the sign of (to designate) an independent individual object, then it is proper to notice that there are many other signs of that nature. We may therefore generalize the meaning of 'term,' and define it (in the general sense) as a sign which does not separately indicate its object, and therefore cannot separately determine its inter-pretant.

The ordinary logics overlook *relative* terms. 'Anything whatever is mother only of things loved by itself' is a proposition beyond dispute, since it is true or false. Therefore it must have a predicate: this is, 'is mother only of things loved by'; or it may be taken to be, 'is mothered only by lovers of'; or, 'loves everything mothered by'; or, 'is either lover of or not mother of'; &c. Relative terms once admitted, it becomes evident

that every verb is a term, the difference between 'loves' and 'lover' being merely that the rules of grammar prescribe different syntax for them. On the other hand, there are various words used in propositions which are not terms, because they cannot take the place of proper names. 'Any' may be considered as meaning 'Whatever is,' or 'The individual which the reader selects,' and so as a term; and in like manner 'Some' may be taken as meaning 'The object the wise friend of the speaker selects,' or something of the sort. Relative pronouns, however, together with the letters *A, B, C*, &c., often used as relative pronouns of an improved kind, if symbols at all, are so extremely like indices that they may for ordinary purposes be so considered.

Abstract terms are matters of extreme importance in all difficult reasoning. Thus, in geometry, we define a *point* as a completely determinate place, an *instant* as a completely determinate time, and a *particle* as that which in any instant is at one point and not at any other. But in a time not completely determined a particle *moves*. We express that by introducing the abstract term *line* as the place in which a particle may be in the course of time. The advantage of doing this is that it enables us to consider relations of lines and their motions, which we could not have done without the abstraction.

(2) A relation is said to have *terms*, which are the objects thus related the one to another. So we speak of the terms of a ratio or proportion.

Absolute term: a term like a common substantive word which connotes nothing.

Ampliate and ampliative terms. An *ampliative* term is a term which when in the predicate causes its subject, the *ampliate* term, to denote more than before. Among ampliative terms are reckoned by Scotus (in *I Priorum*, qu. xvi) verbs in future and past tenses, and future and preterite participles; also such verbs as *potest*, *contingit*, and names derived from them; also *significo*, *intelligo*, *promitto*, and the like, and in general every verb whose object may be indifferently a present or future thing.

Concrete term: a term not abstract, whether it be a substantive or purely denotative term (according to the mediaeval doctrine) or an appellative or connotative term.

Connotative term: a term which, in addition to 'supponere pro,' or directly denoting something, also *connotes* that that principally

denoted thing has some essential or accidental aspect. Such is 'white,' which means 'having whiteness.'

Denominative term: a NAME (q. v.).

[*Designate term* (and *designation*): a term which is used to indicate merely a particular object or class of objects; the application of such a term is 'designation.'—J.M.B.]

Discrete term: a term which denotes one sole individual, but this may be an individual collection, or system.

Exponible term: a syncategorematic word making a proposition exponible, that is, expective, exclusive, reduplicative, inceptive, comparative, &c. (C.S.P.)

Negative term: any portion of experience (whether complicated or not) can be conceived of as a single term a ; all of what is *other than* it is then regarded as the negative of that term, and is represented by $non-a$ (or by \bar{a}). The negative has, therefore, two properties: (2) it fills up the whole of the rest of the field of thought (whether that be absolutely all that is conceivable or merely the immediate subject of discussion), and (1) it is in some essential respect distinct from its positive, so that there can be no object which is at once a and \bar{a} ; in other words, (1) nothing is both, and (2) everything is one or the other. If, following the grammatical device by which we say *large round table* for a thing which is at once large and round and a table, we write ab for things which are at once a and b , and if we write $a+b$ for things which are a or b ; if, moreover, we write o and ∞ for nothing and everything respectively, and \leq for *is*, or *implies*, we may express these two elements of the definition of the negative thus:

(1) $a\bar{a} \leq o$, (2) $\infty \leq a + \bar{a}$.

The second is commonly called the principle of *no tertium quid* or of the excluded middle; the first, the principle of contradiction. But a and \bar{a} are called contradictory terms (and in the case of propositions p and \bar{p} are said to exactly *contradict* each another); it is a pity, therefore, to give the name of principle of contradiction to one only of the two conditions which they must satisfy. It would be much better to call (1) the property of exclusion (or mutual exclusion), and (2) the property of exhaustion (or conjoint exhaustion). These two properties of being mutually exclusive and conjointly exhaustive may be possessed by any number of parts of a whole; thus *equal to*, *greater than*, and *less than* exhaust the relation of relative size and exclude each

other—they may be regarded as a contradictory triplet. When we abstract from all other properties of objects and think of them simply under the aspect of quantity (that is, in mathematics), we state these two properties at once in the form of a so-called axiom; (3) the whole is equal to the sum of its parts; that is, is not greater than (there is no overlapping) and is not less than (there is no falling short, no unoccupied space, no *tertium quid*) its parts when put together. But as thus stated, this axiom is tautologous; what is the meaning of *its parts*, if not the two properties restated in the axiom? It would be better to substitute for this axiom a postulate: things can be separated up into parts which are *distinct* and *constitutive*, that is, which do not overlap and which together fully make up the whole, or which are *exclusive* and *exhaustive*. And as thus stated the postulate applies to the concepts or terms of logic as well as to the quantities of mathematics.

Every term has a negative unless it fills up the whole universe, in which case its negative is non-existent: $\infty \leq a$ is the same thing as $\bar{a} \leq o$. It can be proved that to a given term there is only one negative (Grassmann; Whitehouse, *Universal Algebra*, i. 36). What is the negative of a term which is itself a negative? It must be *all* of that which is *other than* that negative, but this takes us back to the original positive term, or the relation of 'being a negative of' a term is a reciprocal relation; that is, $\bar{\bar{a}} = a$. This last is, therefore, not, as Sigwart thinks, another axiom, or postulate, but a derived proposition. (C.L.F.)

Terminism and Terminists: see OCCAMISTS.

Terminology. [The various sections of this article are supplementary to the terminological matter of the DICTIONARY. The sections are arranged by languages, and in each the terms are in alphabetical order. Cross-references from one of these lists to another always have the word 'above' or 'below' to distinguish them from cross-references to the main topics of the work. In cases in which the recommendation supplements or modifies that made under a leading topic, a cross-reference is made to that topic. The terms included here are indexed in the general Indexes to vol. ii, along with the matter of the DICTIONARY generally, so that the entries in those Indexes suffice for the whole text.—J.M.B.]

TERMINOLOGY

I. ENGLISH.

Affection and Affective: see below. German, GEMÜTHS-.

Affective Logic (or Emotional Logic). The former of these two terms is preferred—since it is broader—as a designation for the supposed process of abstraction, generalization, and symbolization of affective states. Cf. REVIVAL. (J.M.B., W.M.U., E.B.T.)

Ameliorate: see MELIORISM, ad fin. (with foreign equivalents).

Animation: see ANIMISM (meaning 1). Ger. *Beseelung*; Fr. *animation*; Ital. *animazione*.

Critic and Critique. Both of these terms are used for Kant's *Kritik*. See LOGIC, passim.

Emotional Logic: see AFFECTIVE LOGIC (above).

Meaning. This word covers, besides the definition given sub verbo, the terms SIGNIFICATION, INTENT, OPINION, and SIGNIFICANCE (or WORTH); see these topics for foreign equivalents. For signification as connotation there is in German Sinn, and also Bedeutung; but the latter covers significance (as in the phrase 'die Bedeutung dieses Ereignisses') as well, when the idea of value or WORTH (q. v.) is largely that of consequence (in fact or logic). (J.M.B.)

Misoneism: see below, French, MISONEISME.

Moment: the specious PRESENT (q. v.). It is suggested that this term be devoted to this exact meaning, with the following equivalents: Ger. *Augenblick* (H.M.); Fr. *instant*, *présent*; Ital. *attimo*—(E.M.). (J.M.B., H.M.)

Pain and Pleasure: see this topic (1) and (2), and also PLEASANTNESS. In view of the great ambiguity of terms in this subject the following scheme of equivalents is suggested:

Pain and pleasure (in general): Ger. *Unlust und Lust*; Fr. *douleur et plaisir*; Ital. *dolore e piacere*.

Pain and pleasure (sensations): Ger. *Schmerz- und Lustempfindung*; Fr. *sensation de douleur et de plaisir*; Ital. *sensazione di dolore e di piacere*.

Unpleasantness and pleasantness: Ger. *Missfallen und Wohlgefallen*; Fr. *peine et agrément*; Ital. *dispiacere e (sentimento di) piacere*.

(J.M.B., H.M., T.H.F., G.V.)

Significance: see MEANING (above).

Synthetic Form. Proposed rendering of the German Gestaltqualität, as better than FORM QUALITY (q. v.). The proposed French

and Italian equivalents are respectively *forme synthétique* and *forma sintetica*.

(J.M.B., T.H.F., E.M., G.V.)

Will. The following table gives the scheme of terminology recommended, sub verbis, for the various topics under this head (see also the list of terms for conative processes given under CONATION).

	Ger.	Fr.	Ital.
Will	<i>Wille</i>	<i>volonté</i>	<i>volontà</i>
Volition	<i>Wollen</i>	<i>volition</i>	<i>volizione</i>
Intention	<i>Absicht</i>	<i>intention</i>	<i>intenzione</i>
Project	<i>Projekt</i>	<i>projet</i>	<i>progetto</i>
End	<i>Zweck</i>	<i>but</i> ¹	<i>fine</i> ¹
Purpose	<i>Vorsatz</i>	<i>fin</i>	<i>proposito</i>
Plan	<i>Plan</i>	<i>plan</i>	<i>piano</i>
Design	<i>Ziel</i>	<i>dessein</i>	<i>disegno</i>
Means	<i>Mittel</i>	<i>moyens</i>	<i>mezzi</i>
Decision	<i>Entschluss</i>	<i>décision</i>	<i>decisione</i>

¹ See END for other equivalents.

A discussion of certain of these German terms with reference to one another is to be found in Höfler, *Psychologie*, 517 f.; on certain of them see also Eucken, *Gesch. d. philos. Terminol.*, Register, 'Deutsche Termini.'

(J.M.B., K.G., H.M.)

II. GERMAN.

Abscheu: strong aversion, abhorrence (see APPETENCE). Abscheu is one of the contrasted forms of conation which differ only as tending respectively away from or towards an object.

(J.M.B., G.F.S., E.B.T., H.M.)

Allgemein: see under GESAMMT- (below).

Anlage: see RUDIMENT, and ANLAGE. The recommendation of rudiment as rendering of Anlage is supported by the following considerations: (1) It has an adjective form, rudimentary; this is not true of any of the other terms in use (Proton, Anlage, Fundament). (2) It answers as a general psychological term, as none of the others do; this is important, as the psychologists are as much concerned with the term as are the biologists (cf. the citations of the German use of Anlage by psychologists in Eisler, *Wörterb. d. philos. Begriffe*, 'Anlage'). (3) It is used so widely in French and Italian as to be recommended by the consulting editors in both those languages, each quite independently of the other. This makes it a convenient common term in English, French, and Italian. (4) It is quite unambiguous, provided VESTIGE (q. v.) be used for the meaning (2) given under RUDIMENT. (5) Insuperable objections may be urged to the use of each of the other terms

TERMINOLOGY

proposed: i. e. against using *Anlage*—besides what is said under that term—(a) no adjective, (b) no English plural formation, (c) no agreed French and Italian usage; against *Proton*, the same objections; against *Fundament*, the first and third objections, and moreover, the adjective form is ambiguous; against *Primordium*, the second and third.

The neurological authorities (H.H.) of this work sent out a circular asking the opinion of eminent writers as to the best equivalent of *Anlage*. The following table is taken from an article (*J. of Compar. Neurol.*, vii, Mar. 1898) by C. L. and C. J. Herrick, discussing the results of that inquiry. The American and European preferences, given under each term, are indicated by the letters *Am.* and *Eu.* respectively—

Term.	Replies.	Am.	Eu.
Proton	13	7	6
Anlage	11	8	3
Rudiment	9	5	4
Fundiment	6	3	3

Other terms (scattering).

The writers add: 'The term rudiment was in several instances opposed to vestige, thus removing any possible ambiguity. It is probable that this is the consensus of opinion of those who recommend this term.' This consideration—taken with the actual proportion of votes for the term and the availability of the French and Italian forms—seems to make a conclusive case for it.

The biological authority (C.S.M.), however, thinks the use of the German form *Anlage* too deeply fixed to be counteracted. Yet it may be noted that its use is mainly by American embryologists. In psychology, various renderings of *Anlage* have more or less currency: disposition, predisposition, capacity, original endowment, &c. Titchener, who gives disposition, writes (*Amer. J. of Psychol.*, vii, 85): 'None of the words proposed by the morphologists . . . seems to fit the psychology of *Anlage*. And disposition and predisposition are too vague to be really adequate.' These statements are true, and the term rudiment may accordingly have its place in cases in which a specific mental tendency or endowment is in question. For the functional meaning the adjective 'rudimentary' is available, and also the terms *DISPOSITION* and *PREDISPOSITION* as made exact in the definitions given under those topics. For example, we can say that the capacities which reveal themselves in differences of mental type are

in their early stages mental rudiments, that they are rudimentary in their character and place in the mental life, and that in their specific exhibitions (in reaction, in preferential function, &c.) they are predispositions (inherited) or dispositions (either inherited or acquired). In German 'Disposition' (see Eisler, loc. cit.) and in French 'disposition' (see Barth, *Philos. d. Gesch. als Sociol.*, i, 28, quoting Comte) are used for mental *Anlage*.

(J.M.B., H.H., E.B.P., G.F.S., E.B.T.)

Anschauung: *INTUITION* (q. v.). See also *WAHRNEHMUNG* (below), and *INTUITION* (German, below). (J.M.B.)

Bahnung: see *FACILITATION*, which is preferred (following Titchener) to other renderings—such as 'canalization' (Waller), 'path-making' (James)—as available in psychology as well as in neurology. (J.M.B., E.B.T., H.H.)

Bedeutung: see *MEANING* (above).

Beseelung: see *ANIMATION* (above), and cf. *EINFÜHLUNG* (below).

Darstellen: to present, by way of expression, exhibition, or phenomenal appearance; a general, as contrasted with the special, meaning of *PRESENTATION* (q. v.) in psychology. Leibnitz's monads present or represent (*darstellen*, *repräsentent*) the universe at the same time that they have presentations of (*vorstellen*) the universe. (With the noun, as in *Selbstdarstellung*, *SELF-EXHIBITION*, q. v.) (J.M.B., K.G., E.B.T.)

Dressur and **Eindrillung**: training or breaking-in of the type called 'drill,' under *HABITUATION* (q. v.). (K.G., J.M.B., E.B.T.)

Einfühlung: see *SYMPATHY* (aesthetic) (Lipps; who also, *Zeitsch. f. Psychol.*, xxii, 415, uses the more general term *Beseelung*, which, however, has its English equivalent in *ANIMATION*, q. v. above); so also Volkelt, 'Zur Psychol. d. ästhetischen Beseelung,' *Zeitsch. f. Philos.*, cxv. (1898) 161. (J.M.B., W.M.U., E.B.T.)

Einfühlung is not a happy term: (1) because it confuses two distinct things—(a) aesthetic personification (as 'The Gothic tower has an upward impulse'), and (b) inner sympathy (as 'I am carried up with the Gothic tower')—and (2) because the term is too narrow, since the process involved is not confined to feeling. (K.G.)

Einstellung. It is recommended that *Einstellung* be the equivalent of the acquired *DISPOSITION* (q. v.) only, not including the (inherited) *PREDISPOSITION* (q. v.). If *ANLAGE* (q. v. above) be rendered rudiment, then the mental rudiment shows itself as a predisposition, not as an acquired disposition.

TERMINOLOGY

Einstellung has the further meaning of a temporary 'setting' or fixing. (J.M.B., K.G., H.M.)

Empfindsam (and **-keit**): **SENTIMENTAL** (and **-ity**), ad fin. (q. v.). (J.M.B., K.G.)

Geist: see **SEELE** (below).

Gemein-: see **GESAMMT-** (below).

Gemüth: affective-conative disposition or function. See **GEMÜTHS-** (below). (J.M.B.)

Gemüths-: affective-conative (process, &c.). See **AFFECTION**, for the usage of **Gemüths-** as equivalent to affective (see also under **EMOTION**). Titchener (*Amer. J. of Psychol.*, vii. 81) gives this rendering. Eisler (*Wörterb. d. philos. Begriffe*, 'Gemüth') gives the usage of various German authors. The one thing that is common in the various definitions seems to be that cognition, reference to mental objects as such, is excluded (so Waitz, *Lehrb. d. Psychol.*). This means that anoetic consciousness would still be **Gemüth**, whether conation be finally eliminated from it or not. The English word 'temper' comes nearest, possibly, to an adequate rendering (denoting the inner or psychic aspect covered by **Gemüth**, as **TEMPERAMENT**, q. v., sets forth the same as psychological or objectively observed). See the historical note in Eucken (*Gesch. d. philos. Terminol.*, 211 f.), from which we take the following sentence of Volkmann: 'Die Seele wird Geist genannt sofern sie vorstellt, Gemüth sofern sie fühlt und begehrt.' In seeming agreement with this is Wundt's declaration (*pace* his usage!): '... wurde häufig in neuerer Zeit das Fühlen und Begehren in *Gemüth* zusammengefasst und demnach die ganze Seele in Geist und Gemüth gesondert' (*Physiol. Psychol.*, 2nd ed., 11).

(J.M.B., G.F.S., K.G., H.M., E.B.T.)

Gesammt- (in compounds): composite, complex, resulting from the union of parts—as **Gesamtbild**, composite image; **Gesamtvorstellung**, composite (or resultant, Titchener) idea; **Gesamtwille**, **GENERAL** (or **COLLECTIVE**) **WILL** (q. v., see also **TRIBAL SELF**). Cf. also **AGGREGATE** (idea). It differs from **Gemein-** and **Allgemein-** (in compounds) in that it is composite, while they *denote* what is composite.

(J.M.B., E.B.T., G.F.S.)

Gesinnung: moral **DISPOSITION** (q. v.) or character as manifested in **INTENTION** (q. v.).

(J.M.B., K.G., H.M.)

Inbegriff: an inclusive concept; a concept from the point of view of its logical extension. Thus Eisler (*Wörterb. d. philos. Begriffe*) gives the following definition: 'Art: der Inbegriff ähnlicher, innerlich verwandter, Individuen.' Often also simply 'sum total';

e.g. 'the horopter is the Inbegriff of all points seen single by the two eyes.' (J.M.B., E.B.T.)

Intuition: covers **Anschaung**, but in the way of overlapping. **Anschaung** is direct apprehension *as direct*, and it includes sense-perception; **Intuition** is direct apprehension as valid, rational, mystically true (the *intuitio intellectualis* of the mystics), and hence it is not generally used of sense-perception. Yet it is used of 'inner' apprehension at the same level as sense-perception. This is the distinction in general; it varies in the usage of particular writers. Cf. **WAHRNEHMUNG** (below). Cases are given by Eisler, *Wörterb. d. philos. Begriffe*, sub verb.

(J.M.B., K.G.)

Perception: see **WAHRNEHMUNG** (below).

Seele and **Geist**. In general usage **Seele** has come to mean mind as a whole in contrast with **Geist**, the intelligence, and **GEMÜTH** (q. v., above), feeling and will; that is, the phenomenal mind, as is seen in the terms **Seelenleben**, **Seelenvermögen**, &c. The meaning 'soul' accordingly falls into the background, and is brought out by some such terms as **Seelensubstanz**. In adjective forms, however, this difference is obscured, e.g. **Geisteswissenschaften** (mental science), **Geistesstörung** (mental disorder). **Geist** is sometimes used when opposition or lack of connection between mind—i.e. **SPIRIT** (q. v.)—and body is brought out (**Geist** und **Körper**); **Seele**, when the relation between them is had in mind (**Seele** und **Leib**). Originally, **Seele** meant the breath and then the life principle (as the $\psi\chi\eta$ of the Greek and the *nephesh* of the Hebrew); and the context often gives it still the descendant-meaning soul, as in **Seelenwanderung**, **Seelen-errettung**, **Seelensitz**, &c. Eisler, *Wörterb. d. philos. Begriffe*, gives citations; and discussion of the two terms is to be found in Wundt, *Physiol. Psychol.*, Einleitung, 2. Cf. **ÂME** and **ESPRIT** (below).

(J.M.B., K.G., H.M., E.B.T.)

In scientific usage, **Geist** is avoided altogether, **Seele** is used for soul, and mind is expressed by **das Psychische**, **geistige Erscheinungen**, &c.

(H.M.)

Selbstzweck: see **AUTOTELIC**. In English there is no noun for this concept of the 'self-end'; but the adjective 'autotelic' may supply the need, as in the phrase 'autotelic function' (a function having a **Selbstzweck**). (J.M.B.)

Sensibel: see **SINNLICH** (below), and cf. **WAHRNEHMUNG** (below).

Sensibilität: sensibility in the technical meaning given it by some (Kölpe) when

TERMINOLOGY

Empfindlichkeit is translated by SENSITIVITY (q. v., especially remarks ad fin.). (J.M.B.)

Sinn: see MEANING (above).

Sinnlich: see SENSUOUS. Often equivalent to sensibel ('sensible' and 'sense-'; see SENSE DISCRIMINATION, ad fin.) and to wahrnehmbar. The noun Sinnlichkeit denotes the perceiving function (or faculty), being thus broader than Empfindlichkeit. (J.M.B.)

Sinnlichkeit: see SINNLICH (above).

Ueber-: equivalent to Lat. HYPER- (q. v., in philosophy) or Super-, which are used as English prefixes: so Ueberindividuell (see OVERINDIVIDUAL), Uebermensch (Nietzsche). (J.M.B.)

Uebung: see PRACTICE. The recommendations made *in locis* may be thrown together here with the English and other equivalents.

UEBUNG, PRACTICE, PRATIQUE, PRATICA.

1. Vorübung, preparation, préparation, preparazione.
2. Einübung, habituation, accoutumance, assuefazione.

3. Ausübung, exercise, exercice, esercizio.

The German terms are already in use (notably in Groos, *Spiele der Thiere und Spiele der Menschen*); hence the insertion of the table under this head. (J.M.B., G.F.S.)

Umfangsempfindlichkeit: RANGE (q. v.) of sensibility or sensation values (see Höfler, *Psychologie*, 92). (J.M.B., G.F.S., H.C.W.)

Verständlich: comprehensible (see COMPREHENSION). Used also in compounds, as *selbstverständlich* (self-evident), *unverständlich* (incomprehensible), &c. (J.M.B., K.G.)

Wahrnehmbar: see SINNLICH (above).

Wahrnehmung: PERCEPTION (q. v.); the process of the apprehension (Auffassung) of present objects. (Sinnes-) Anschauung is rather 'sense-intuition,' the recognition of present objects as such, apprehended by little or no subjective process, or even with denial of such process (cf. INTUITION, 1). It belongs especially to sense-objects, but is often carried up in its meaning; while the German term Perception seems to belong mainly to objects in general and to be carried down to sense-objects, so as to overlap Wahrnehmung. (Wundt's use of Perception, for apprehension without attention, is in line with Leibniz.) For citations of the use of Perception see Eisler, *Wörterb. d. philos. Begriffe*, sub verb. (J.M.B., K.G.)

Willens- and Willkür- (in compounds): see CONATION for a general scheme of German equivalents for conative processes, where through error these two terms are reversed. Willens- should be given for VOLUNTARY (q. v.), and Willkür- for volitional. This agrees with

Titchener's rendering, if we assume that his 'selective action'—Willkürhandlung—means VOLITIONAL (q. v.) action. It is supported by Höfler's decision as to Willkür- ('willkürlich = das Gewollte,' *Psychologie*, 512). Höfler, however, rejects the term Willens- (handlung) altogether as being too ambiguous in current German usage (ibid. 535 f.). Judd (Eng. trans. of Wundt's *Outline of Psychol.*, 'Glossary') gives volitional for Willens- and voluntary for Willkür-, but reverses the meanings which we give for the English terms (i.e. he makes volitional = the lower conative, and voluntary = the higher or 'willed'—that which involves an act of volition). This means that he agrees with our recommendation as to the meanings of the German terms, but applies to them (*nobis iudicibus*) the wrong English equivalents. (J.M.B., G.F.S.)

III. FRENCH.

The difficulty of acquainting oneself with French and Italian usage is enormously enhanced by the lack of Indexes in the books. It is their own fault if authors in these languages continue to handicap the use and appreciation of their books as works of reference, and even for topical reading, by this extraordinary limitation. That they continue to make this omission—or to allow their publishers to make it—is unaccountable to the worker in English or German.

On French renderings for scholastic terms see the *Rev. Néo-Scholastique*, 1898–1902, for a series of articles. (J.M.B.)

Âme and Esprit. In the usage of these terms we find a development analogous to that of the German SEELE AND GEIST (q. v., above). Like Geist, esprit meant at first breath (*πνεῦμα*), then the life principle, and finally spirit, considered as that which is separable or separated from body; over against this, âme is the soul *in the body*, the soul in relation to *its* body. Then the predominant function assigned to intelligence in the rational or spiritual principle led to the transition by which esprit came, like Geist, to mean the intelligence, while âme in contrast meant mind as a whole (cf. the article 'Esprit' by De Rémusat in Franck's *Dict. des Sci. philos.*). There is a similar shading of meanings in popular English usage of the words soul and mind. We say a man has little soul, meaning that he has little sentiment, feeling, 'heart'; but when we say he has little mind, we mean little intelligence.

(J.M.B., TH.F.)

Esprit: see ÂME AND ESPRIT (above).

Forme synthétique: see SYNTHETIC FORM (above).

Misonéisme: Misoneism, or hatred of the new (cf. Neophobia, under NEO-); used by Féré in a pathological sense, and by Lombroso (*Monist*, Apr. 1891) for social conservatism. (J.M.B.)

Mobile: see AFFECT. This term is already in use in such expressions as 'premier mobile' (prime mover), 'garde mobile,' &c.; and in its common signification of 'mover,' 'moving power,' &c., takes on readily the meaning suggested. (J.M.B., G.F.S., E.B.T.)

Tertium quid [Lat. for third something]. A medium or third thing through which a relation is established or maintained between two other things. See MIDDLE TERM, and PERCEPTION, ad fin. (J.M.B.)

Tertullian (**Quintus Septimius Florens Tertullianus**). (160–220 A.D.) Liberally educated, he became a lawyer of first rank and professor of rhetoric in his birth-place, Carthage. Converted to Christianity, he experienced a profound change of heart, becoming rigidly devout where he had formerly been indifferent. See PATRISTIC PHILOSOPHY (4).

Test (psychophysical): Ger. *Probe*, *Prüfung* (no adequate equivalent for 'test'—K.G.); Fr. 'test,' *épreuve*; Ital. 'test,' *prova* (De Sanctis), *saggio*. A determination of the normal character or marks of an organ or process together with its functional efficiency.

Measurements and tests form the basis of ANTHROPOMETRY (q. v.), and are valuable in the investigation of physical and mental development, of the correlation of physical with mental traits, and of mental traits with one another; of the effects of special training, of fatigue, of the action of drugs, &c.; as also in the elucidation of psychological methods, in the determination of the range and nature of individual variation and of class differences, and in the study of many of the general analytic problems of psychology. Those who lay stress upon the analytic and explanatory functions of psychology prefer to speak of the study of mental processes in respect to their functional efficiency as mental anthropometry; but the problems of mental anthropometry must be liberally interpreted, and their truly psychological as well as their practical character must be fully recognized. It should also be noted that results of mental tests frequently possess a considerable statistical value, even when their bearing upon individual characteristics seems uncertain or accidental.

Indeed, many of the problems of mental anthropometry are in nature statistical; and the application of the results to individual cases is often impossible, or of minor significance. The results of tests upon groups of individuals (pupils of various ages, boys and girls, the professional and labouring classes, the leisure and the unfortunate classes, &c.) often possess a maximum of interest and reliability.

Tests of bodily efficiency or capacity most usually brought into relation with mental tests are strength tests of various groups of muscles and breathing capacity; bodily height and weight, chest girth, size of head, height sitting, length of arm, &c., are usually recorded, as are also age, sex, nationality, occupation of father, and other personal details. Determinations of the speed, steadiness, accuracy, and character of movements, and the physiological efficiency of eye and ear—all involve some psychological factors, and are usually included in a psychological series.

What tests shall be excluded and what included in any series naturally depends upon the purposes of the investigation. When the tests are made, not in the execution of a special end or purpose, but with the general object of securing data of individual and class value, likely to yield significant, valid, and interesting results, the tests have, in the main, been composed of a selection from the following representative list.

A. *Tests of sensory capacity*: (a) for the eye, keenness and range of vision, correctness of colour vision; (b) for the ear, keenness of hearing, range of pitch-hearing, accuracy of discrimination of pitch; (c) for the skin, keenness of touch, sensibility to pain. (To be separately enumerated as involving both sensory and motor factors is the keenness of the muscle-sense combined with touch: see C, 4.)

B. *Tests of motor capacity*: (a) energy of contraction, e.g. the maximum pressure exerted upon a dynamometer by the right and left hands; (b) speed of contraction, e.g. tapping or trilling on a telegraph key at a maximum rate for ten seconds; (c) quickness of movement, e.g. the time needed to move the hand over a given distance; (d) accuracy and steadiness of movement, e.g. moving a point in a narrow groove without touching the sides of the groove, touching a given point with the end of a rod, throwing an object at a target (this group of tests as usually performed involves the co-ordination of eye and hand, and should properly be enumerated under a separate heading).

TEST

C. *Tests of perceptive capacity*: usually the accuracy of perception for small differences: (1) in sight, small differences of length, or area, or form, or position, or colour, or combinations of these; (2) in hearing, small differences of pitch or loudness of sounds; (3) in touch, small differences of length, or form, or texture (as roughness, softness); (4) in muscle sense and movement, small differences of weight by lifting, of length or form by moving the finger along contours; (5) in the time sense, small differences of time intervals between audible taps or visible or tangible signals.

D. *Tests of mental alertness and quickness*: (a) the time of response to a stimulus (simple reaction) addressed to the eye, or ear, or skin; (b) time of discrimination, as in indicating all the a's in a printed page, finding all the reds in an array of colours, or a given form amongst a group of forms; (c) time of distinction and choice, as in reacting by different and appropriate movements according to the object presented; as in sorting colours, forms, or letters into different boxes, or in touching a designated key according to which one of a number of different stimuli is made to appear.

E. *Tests of memory and of more complex mental processes*. (a) *Memory*: (1) range or span of memory, e.g. the maximum number of numerals or letters or nonsense-syllables which can be repeated after a single hearing or a single reading; (2) the accuracy of memory in reproducing or in recognizing more extensive series of sense-impressions, and the determination of the kinds and frequency of errors; (3) the type of memory, especially in regard to language, to what extent in terms of ear, eye, or muscle images; (4) duration of memory, the loss in vividness and accuracy after varying intervals of time. (b) *Association*: the time of response to a sense-impression or word by an associated impression, e.g. the time needed for a word heard or seen to arouse a related word, the time needed to answer a question depending upon a simple memory-association, to translate from one language to another, the time of multiplication or addition, the time needed to classify an object as belonging to a certain class, &c. The nature of the associations (or errors) may be suggestive. (c) *Attention*: concentration, as tested by susceptibility to intensity and kind of distraction. (d) *Imagination*: the vividness and nature of mental imagery as determined by general queries. (e) *Inventiveness* or logical alertness; as tested

by the ability and quickness in solving simple puzzles. [(f) *Constructiveness*: tested by the ability and time required to fill in unfinished sentences correctly or intelligibly.—J.M.B.]

F. *Observation and judgment*: e.g. the correctness with which the number of steps in a familiar flight of stairs can be recalled; with which the arrangement of the doors and windows, or the size and proportions of the floor-plan, of a familiar building can be reproduced; the accuracy with which the sizes of familiar objects (current coins, stamps, or notes) can be reproduced or estimated in inches; or with which impressions frequently seen, but not consciously attended to (the shape of the prints of a dog's foot, the arrangement of the seeds in an apple), may be summoned to mind and reproduced.

G. *The aesthetic judgment*: this has occasionally been tested by means of tabulating preferences of colours or of colour combinations, or judgments of the proportions of the sides of a rectangle, or the diameters of an ellipse, which are most pleasing.

H. *Interest*: interest has been tested by observing what details in a complex picture are selected for description, and the order and prominence of the points noticed; by asking for definitions or descriptions of simple objects and noting the character of the definitions, whether in terms of use, logical classification, external qualities, or others.

The above enumeration aims to include the more usual forms of mental tests; in several groups other tests may be of almost equal importance. Under group A, tests of absolute sensitiveness to light, or of the period of formation or duration of after-images, or tests of the delicacy of taste or smell, may be introduced; under B, degree of righthandedness, or of the effect of fatigue, or of the susceptibility to unconscious movements, or a general test of endurance; under C, the accuracy in judging when lengths or angles are divided in half, when lines form true right angles, or of rhythm in movement; under D, the time required for an impression (a letter, a colour, &c.) to act upon the retina long enough to be recognized, and various other forms of distinction and choice. The complexity of group E offers a large variability amongst the constituent factors of the processes involved. Conditions of weather and season, time of day, state of the subject's health, his preferences and distastes, his talents and deficiencies, his estimated standing in school studies, his ability to improve with

moderate practice, &c., have been noted in special researches and utilized in the determination of the correlation of these with mental conditions and processes.

The determination of the method of conducting a mental test is of co-ordinate importance with the selection of the most serviceable tests. The more general and important methods which are applicable to more or less extended groups may be enumerated as the methods of reproduction, of selection, of identification or recognition, of arrangement in order, and the recognized **PSYCHOPHYSICAL METHODS** (q. v.). Cf. **MEMORY** (experiments on).

Certain of these may be illustrated by the test of the capacity to distinguish between small differences in lengths of lines. A single pair of lines may be repeatedly shown, and the frequency of error in determining which of the two is longer may be recorded (*method of right and wrong cases*); various pairs of lines may be shown, and the degree of difference between them, which disposes the subject to venture a judgment as to which is longer, may be recorded (*method of just noticeable difference*); a line (or lines) may be shown and the subject be required to repeatedly draw a line equal to it (or them), and the average deviation of the reproductions from the standard as well as the variation of the several reproductions among one another may be recorded (*method of average error*). As described, the last method also exemplifies the method of *reproduction*; if a line equal to the standard is to be selected from a graded series of lines, it involves the process of *selection*, the degree of error and regularity of the process being still an item of record; if the standard line occurs irregularly among a large group of lines of various lengths, and is to be identified or recognized when it occurs, the method passes into that of *identification or recognition*, the frequency of correct recognition forming the main record, and the degree of error becoming of secondary importance (and in many cases not determinable). If a group of three, or five, or more lines forming a suitable series be presented in irregular order of length, and the subject be required to arrange them in correct order, the correctness of the arrangement (with reference to the degree of difference between neighbouring members of the series) and the degree of deviation from a correct order are recorded (*method of arranging in order*). While the problem of methods has been pre-

sented mainly in regard to the perception of small differences, it must also be considered in more or less modified form in other connections. Thus, memory may be tested by reproduction, or by identifying the original impression when and where it recurs; this involves the two functions of memory as the power of recollection and of recognition. Tests described under **D (b)** illustrate the method of recognition or identification; similarly, in memory-tests a group of words, forms, or colours may be shown a second time with some modifications from its appearance when first exhibited, and the number of the points of difference which can be detected and described becomes the record of the test. The merits and demerits of these and of other psychophysical methods cannot be here considered; but the importance of the criteria of practical, simple, and ready applicability, and again of easily computable and unambiguous results, may be emphasized.

Apparatus. Along with tests and method, the selection of apparatus and the details of execution of the test should receive careful consideration. Simplicity of construction and of manipulation, quickness in reaching the result, and appeal to natural interests, are requisites for general tests, as is also a maximum amount of definiteness in regard to the particular capacity which is tested. An enumeration of the more usual apparatus and devices used in connection with some of the above-mentioned tests may be appended.

A. (a) For keenness of vision the size of letters or forms which the eye can see or read at standard distances; these are measured by diopters (see **VISION**, defects of); for tests of colour-defect and colour-blindness see **COLOUR-BLINDNESS**. **(b)** For hearing, the maximum distance at which the tick of a watch can be heard by each ear separately; audiometers, in which the intensity of the sound is measured by the amount of resistance introduced into the circuit, have been successfully used. For the lowest audible tones a steel blade adjustable in length, or a set of wire forks (both made by Appunn), give the needed vibrations of from 12 to 30 per second; while for the upper limit a Galton's whistle (recently much improved in precision), or a set of steel bars of graded pitch, is satisfactory; for pitch differences a pair of adjustable tuning-forks, or an extensive set of graded tuning-forks, or a pair of variable tones produced, e.g., by a Gilbert's tone-tester, are necessary. **(c)** Keen-

ness of touch has been measured by the minimum weight which will arouse a sensation of contact, by the aesthesiometric test of the minimum distance between two points which can be felt as two; while sensibility to pain is usually recorded by the lower limit of a steady pressure at which pain is felt.

B. (a) The dynamometer in various forms is used; and if a written record is desired, an ergograph will record the degree of muscular effort exercised, and also the nature of the contraction and the aggregate amount of work performed by successive maximal contractions.

(b) A key connected with an electric counter, or with a registering point on a kymograph, or with a mechanical counting device (or simply tapping rapidly with a pencil on a strip of paper), will measure rapidity of contraction. (c) This requires some accurate timing apparatus (see group D). (d) A narrow wedge-shaped slit in tin-foil cemented on glass, the subject being required to guide a needle point as far as possible towards the point of the wedge until the point touches the foil and closes an electric circuit; for the wedge-shaped slit may be substituted a narrow groove of more or less intricate design, the number of contacts in guiding the point along it being recorded; or the labyrinthine design may be printed in double parallel lines in colour, and a pencil guided between the lines. A description of a test for accuracy of aim is given above.

C. (1) For sight, printed lines, squares, circles, letters, &c., specially devised forms (form-alphabet) and colours offer easily constructed objects for the perception of small differences of length, area, shape, and colour. (2) The tone-testers and tuning-forks described above, A (b), are used. (3) For judgment of lengths, sticks or bars, or the sides of simple figures cut out of smooth cardboard, are satisfactory; and graded sets of cloths of variable mesh (bolting-cloths) or forms wound with graded wires are used for testing sensibility for relative roughness and smoothness. (4) Weights to be lifted are generally enclosed in uniform boxes of wood or hard rubber. (5) Tests of the time-sense involve the use of a metronome, tapping-key, recording tambour, or electric pen and kymograph.

D. The apparatus for this group includes a piece for measuring small intervals of time; the Hipp or d'Arsonval chronometer, the Fitz or Scripture pendulum, and the registering tuning-forks represent different types of this apparatus (see REACTION TIME). The

accessory apparatus consists of single and complex (five-finger) keys for reacting, of a means of producing simple sounds, of an exposure shutter for revealing letters, words, colours, &c., of a speech-key for recording the moment at which a sound is uttered, and of the usual electric accessories. Of devices for measuring single reactions by simpler mechanical apparatus, the principle of the differential pendulum offers the best promise of success and adaptability for general tests. If groups of successive reactions are to be measured, a stop-watch or an ordinary watch becomes sufficiently accurate; and the process of sorting cards, with colours, words, pictures, letters mounted on them, or of selecting all of a certain kind of impression from a large group of miscellaneous impressions, becomes a convenient form of experimentation.

E. For auditory memory articulated sounds offer a sufficient variety of impressions; for visual impressions a screen or shutter to expose objects for brief or longer periods, simultaneously or in uniform succession, is needed. For the remaining groups the required apparatus and accessories will be readily gathered from the descriptions given above.

Test Types: Ger. *Buchstabenproben, Sehproben*; Fr. *optotypes, caractères pour l'examen de l'acuité visuelle*; Ital. *tipi di prova ottica, scale di Snellen*. Quadrangular letters and numerals for the determination of the range of distinct vision.

The 'standard' eye (Snellen) sees two black objects on a white ground as discrete when the space between them subtends a visual angle of 1'. The test types in regular use are so chosen that the smallest can be read, by the normal eye, at a distance of 6 m. Acuity of vision is in this case expressed as $\frac{6}{v}$ or $\frac{1}{v}$. If only the largest types on the sheet can be read at 6 m., $v = \frac{6}{60}$, i.e. the patient can read at 6 m. what he would, with a normal eye, read at 60 m.

Testament (in law) [Lat. *testamentum*]: Ger. *Testament*; Fr. *testament*; Ital. *testamento*. A voluntary disposition of all or part of a man's property, or rights, to take effect only upon his death; a will.

In the phrase 'will and testament,' the last two words are mere surplussage.

In early English law, the term testament was specially appropriated to wills of personal property, which came under the probate jurisdiction of the ecclesiastical courts; but for centuries 'will' and 'testament' have been synonyms (Bacon's *Abridgment*, Wills, A). 'Testamentum est voluntatis nostrae iusta sententia de eo quod quis post mortem suam fieri velit' (*Dig.* 28, 1, *Qui testamenta facere possunt*, &c., 1). The soul of the Roman testament was the naming of a universal successor, or 'haeres.' See WILL (in law). (S.E.B.)

Testament (The Old and The New): Ger. *Testament*; Fr. *Testament*; Ital. *Testamento*. Names applied to the Hebrew and Christian Scriptures.

The terms signalize their character as a testament or will sealed in the blood of the testator, symbolically in the sacrifices of the Old Dispensation, really in the sacrifice of Christ in the New Dispensation. (A.T.O.)

Testimony [Lat. *testimonium*, from *testis*, a witness]: Ger. *Zeugniss*; Fr. *témoignage*; Ital. *testimonianza*. The statement of a witness used as evidence, whether depositional or documentary.

Deposition is oral or written. All testimony is either *direct* or *circumstantial*. *Direct* testimony is a statement of the very fact in question. Testimony is, further, either *intentional* or *casual*. Intentional testimony is a statement made for the purpose of persuading those before whom it is laid of the truth of the facts in question. Testimony is further either *original* or *second-hand*. Original testimony is testimony to percepts, or perceptual judgments, of the witness. *Second-hand* testimony is testimony as to what the witness learned by testimony (strictly by original testimony, otherwise it would be third-hand, &c., testimony, or *rumour*).

There is a general tendency to believe what one is told; and, as in the case of other such tendencies, it should at first be followed, although cautiously and tentatively. Even when experience is wanting, as for example in examining a prisoner, although greater caution is required, the proper course is to begin with the presumption that the testimony is true, for unless we make such a presumption, no truth can ever be discovered. It is true that the unlikelihood of the matter of the testimony may cause immediate distrust, or even disbelief of it, but no persons are so frequently deceived as those who stop to weigh likelihoods before accepting or rejecting testimony, and who then form a confident opinion *pro* or *con*. Testimony should almost always be accepted as approximately correct, but always strictly on probation, as a subject of examination. In our legal proceedings, witnesses are subject to cross-examination. Everybody is agreed that this is an essential step in the inquiry, but in a historical inquiry no such thing is possible. Still the testimony can be tested in various ways; and this must be done. But in any case, the rendering of the testimony is a fact which needs to be accounted for; and by whatever theory it be proposed to account for it, that theory needs to be checked and tested. Properly handled, false testimony may often yield a great deal of information.

An experimental test may be readily performed by considering the least antecedently likely but necessary or highly probable consequence of the theory, which is susceptible of being confronted with observation direct or indirect. If this consequence is found, notwithstanding its unlikelihood, to be true, there is then some reason for believing in the theory proposed to account for the testimony. (C.S.P.—J.M.B.)

Test of Truth: Ger. *Kriterium* (or *Kennzeichen*) der Wahrheit, *Test* (little used); Fr. *critérium de la vérité*; Ital. *criterio della verità*. The criteria, standards, or norms for the ascertainment and recognition of truth and the distinction of truth from error are called 'tests of truth.'

In a broad sense, the means, of whatever kind, for the detection of errors of sense and for testing the accuracy of memory, the rules of logic, laws of evidence, canons of investigation in the various departments of inquiry, principles of authority, standards of opinion, &c., constitute such criteria or tests. More specifically as well as more technically, philosophical thinkers have distinguished between formal criteria and material criteria, between the tests of ultimate and derivative, rational and experiential, *a priori* and *a posteriori* truth. The formal criteria, as the name implies, relate to the form rather than to the content of propositions, and comprise the rules and canons of logic, the fundamental laws of thought; they have often been summarily stated as freedom from contradiction and consistency (*Widerspruchslosigkeit* and *Folgerichtigkeit* or *Konsequenz*: cf. Krug, *Wörterbuch*, sub *verbis*). The material criteria or tests of material truth have to do with the matter or content of knowledge; and the debated question arises whether it is possible to frame, or even to conceive, any one criterion or sets of criteria sufficient in all cases to distinguish between material truth and falsity. In opposition to the endeavours to establish such a test, many writers have urged, over and above the specific criticism of their principles suggested by different philosophers, that the idea of a universal material criterion is self-contradictory, since, as universal, it could not be made applicable to the various material contents in their particularity (cf. Kant, *Krit. d. reinen Vernunft*, *Werke*, Hartenstein, 2nd ed., iii. 86-7). In general, the preponderant movement of opinion is in favour of recognizing the plurality of criteria, formal and material, in correspondence with the various processes of thought and departments of knowledge, and against the search for a universal criterion, in spite of the classical attempts to discover one which have been made in modern times, e.g. the Cartesian advocacy of clearness and distinctness (Descartes, *Meditationes de Prima Philosophia*, iii; Leibnitz, *Méditationes de Cognitione, Veritate, et Ideis*: see also CLEARNESS AND DISTINCTNESS), as well as in antiquity (cf. E. Zeller, *Stoics*,

Epicureans, and Sceptics, ii. v. B, on the criterion of the Stoics and its central position in their theory of knowledge). The distinction between first, intuitive, or *a priori* truths and experiential or factual truths brings into prominence the inquiry after criteria or tests of principles of the former kind. These have been variously formulated by different writers: universality in the sense of universal acceptance, known also as universal consent or catholicity (cf. Locke, *Essay concerning Human Understanding*, I, esp. I. i. 2-24, and Leibnitz, *Nouveaux Essais*, I, esp. I. i. 2-4), or in the sense of being true without exception (Kant, op. cit., 34-6), necessity, and evidence or self-evidence have enjoyed the greatest favour, while simplicity, incomprehensibility, independence, immediacy, irresistibility, &c., have also been proposed (cf. Sir W. Hamilton, *Reid's Works*, note A, iv, vi; J. McCosh, *First and Fundamental Truths*, 16-18, 34-57). Herbert Spencer defends the inconceivability of the negation—called by him the UNIVERSAL POSTULATE (q.v.)—as an adequate test of primary truths, which he holds to be *a priori* in the individual as the result of inherited experience, although they are *a posteriori* in the race (*Princ. of Psychol.*, §§ 420-37; cf. J. S. Mill, *Logic*, 8th ed., ii. vii. 1-4, and see INTUITIONALISM). Besides the criteria of truth at large and the tests of theoretical principles, attention has often been directed to the principles of morals and of taste as canons of ethical and aesthetic truth. In regard to such further questions as the relative authority of thought and feeling, reason and faith, reason and revelation, &c., see AUTHORITY, FAITH PHILOSOPHY, RATIONALISM, and REVELATION. See also SCEPTICISM, TRUTH, and ERROR. (A.C.A.JR.)

Tetanus [Gr. *tetavós*, rigid, from *teíneiv*, to stretch]: Ger. *Starrkrampf*; Fr. (*l'*)*état tétanique*, *tétanos*; Ital. *tetano*. A state of continued contraction of a muscle due to rapid stimulations from a nerve centre.

A common case is that popularly called lockjaw. (J.M.B.)

Tetens, Nicolaus. (1736-1807.) Born and educated in the Landschaft Eiderstedt, he became professor of physics in the Pädagogium at Bützow in 1763; later, also director. After 1776 he was professor of philosophy at Kiel, and later of mathematics. In 1789 he became assessor, then councillor, in the college of finance at Copenhagen, where he died.

Text-blindness: see WORD-BLINDNESS.

Thales. (cir. 640–cir. 550 B.C.) A native of Miletus who founded the school of Ionian or Hylozoic philosophers, and who is called ‘the father of philosophy.’ One of the Seven Sages, a mathematician and an astronomer, he was also a man of affairs. No writings of his remain. See PRE-SOCRATIC PHILOSOPHY, and SCHOOLS OF GREECE (Milesians).

Theanthropism: See ANTHROPOMORPHISM.

Theism [Gr. *θεός*, God]: Ger. *Theismus*; Fr. *théisme*; Ital. *teismo*. Theism is a term that may be applied either to a form of religious belief or to a philosophical theory. In the former sense, as a designation of religious belief, it has a broader and a more restricted meaning. Broadly, it may be applied to any form of religious belief which regards the object of its worship as supra-human, and in this sense will include not only henotheism and monotheism, but polytheism in its most undeveloped forms, as fetichism and ghost-worship. In the restricted sense the meaning of the term is limited to monotheism, and involves the belief in one Supreme Being who is the author or ground and governor of the world. Even as thus restricted theism will include three species, pantheism, deism, and what may be called theism in the specific sense. Cf. the various topics (especially philosophy and psychology of) RELIGION.

If we represent pantheism as a belief which does not distinguish God from the world, and tends to regard the deity as an impersonal principle, and deism as one in which God is not only distinguished from the world but is conceived as bearing to it the relation of a *deus ex machina*, theism may then be defined as belief in a personal being transcending the world in his nature, but not separated from it in his agency. Theism, in short, as a well-defined species involves a belief in the personality of the deity, as well as in his transcendence, in a sense that is not inconsistent with the immanence of his presence and agency in the world and in man.

I. *Theism treated as a religious belief.* The elements involved in the above definition are to be regarded as parts of a concrete, and, therefore, as implications rather than as definitely conceived characteristics. Theism, like pantheism, will exist as an attitude or disposition before it has taken the form of a conscious theory. In this sense it is clear that the history of theism, in the broad sense, will be bound up with that of the origin and development of religion in general, and will include

the lower species or forms, such as fetichism and ghost-worship, as well as the more developed forms, polytheism, henotheism (uncritical monotheism), hylotheism (the belief that the material world is God), and monotheism.

But taking theism as defined above, it is evident that it will be exclusive of all pluralistic (polytheistic) forms and will have monotheism as its presupposition. The questions of its origin and development will, therefore, be bound up with the fortunes of monotheism. Cf. RELIGION (evolution of).

Without entering into the disputed question whether, historically, monotheism preceded or followed polytheism, or whether both grew out of an earlier form called henotheism, as Max Müller contends, we may safely maintain that, logically, monotheism represents the most developed form of religious belief. From this point of view theism is to be regarded as *that form of monotheistic belief which differentiates itself from pantheism, on the one hand, in the emphasis it places on the personality of God and his distinction from the world; and from deism, on the other hand, in its insistence on the immanence of the divine in man and the world.* Of the three distinctively monotheistic religions, Judaism, Christianity, and Mohammedanism, it will be evident that Christianity is the most developed in its theistic conceptions. In Judaism, and especially in Mohammedanism, the tendency at least is to assert the unity and transcendence of God at the expense of personal attributes and immanence. Christianity also insists on unity and transcendence, but its doctrine of the Trinity is evidence of the emphasis it places on personality, while its whole doctrine of the Holy Spirit is one of immanence.

II. *Philosophical theism.* This may be defined as critical theism, or *the theory that the universe is grounded in one infinite and absolute Being, whether the relation of this Being to the world be conceived pantheistically, deistically, or in a definitely theistic sense.* If philosophical theism be distinguished from the religious belief called theism, which, of course, it presupposes, it will be evident that here the issue between polytheism and monotheism will be transcended at the outset. Philosophical theism could only arise out of an effort of human thought to unify the world under the concepts of religion, and a plurality of deities would simply represent an irrational situation that was to be overcome before any real unification could be effected. Philosophical theism thus presupposes monotheism,

but must not be confounded with it. It is possible for monotheism to become reflective even without reaching the ground of philosophical theism. For example, among the early Greeks it is clear that Xenophanes reached his monotheistic creed through a process of reflection which led him to oppose the polytheism and anthropomorphism of the current religious beliefs. His position may therefore be regarded as an advance towards philosophical theism, but it is lacking in one important essential of that theory. So far as the records show it did not occur to Xenophanes to translate his monotheism into a principle of world-explanation. It was necessary that the gulf between theology and cosmology should be bridged over in the thought of some thinker before philosophical theism could be born. This great step seems to have been taken (with partial consciousness at least) by Anaxagoras, who, in postulating *vous* (reason or intelligence) as the first principle and unifying ground of things, laid at the same time the foundations of a theistic conception of the world.

It is possible here to note only the most important stages in the development of distinctively philosophical theism. Passing over the thought of the Orient, which tended to pantheistic conceptions in religion (see *ORIENTAL PHILOSOPHY*), and confining our view to that of the Western nations where the stages of the evolution are clearest, it may be said that the first great cycle of theistic development was accomplished in the reflection of Socrates and his immediate successors Plato and Aristotle. Socrates made the first application of the theistic principle in the sphere of the adaptation of means to ends in organic nature, and thus became the first exponent of what has since been called natural theology. Plato universalized the principle of Socrates, and, conceiving it in an ontological sense, identifies it with the idea of the Good, thus originating what may be called the onto-teleological method of conceiving God in relation to the world. Theism in Plato is mainly a principle of transcendent design and purpose, which is related to the world in a somewhat deistical sense. Aristotle translated this principle into one of immanent cosmology without sacrificing its teleological character. This is the significance of his doctrine of the 'Prime Mover' (see 'Mover and moved' under *MOTION*, *passim*), whose self-activity is conceived to be the prius and spring of the world-movements.

The theism of Aristotle may therefore be characterized as cosmo-teleological, embodying as it does a synthesis between the transcendent purpose of Plato and the immanence of a cosmic principle. In the later Greek movements we find the immanent tendency dominating the thought of the Stoics and translating their religious conceptions into a species of cosmic pantheism, while in the later developments the transcendent teleology of Plato again triumphs, and in the movement called Neo-Platonism, which was also tinged with oriental mysticism, the religious conceptions take on the theosophic form, and the notion of God as a cosmological principle is largely lost in that of his transcendence and unity. This accounts for the tendency of this thought to renounce the phenomenal world, and to regard it as pure negation and evil. Cf. *SOCRATIC PHILOSOPHY, SCHOOL OF GREECE, and ALEXANDRIAN SCHOOL*.

The initial movement of our era may be briefly characterized as a struggle, more or less successful, of the implicit theism of Christianity, which we have seen to be synthetic, to overcome the one-sidedness of the later Greek thought by emphasizing the personality or internal complexity of the divine nature and the immanence of its relation to the world through the agency of the Spirit. In the scholastic period, which first Platonic and, later, Aristotelian thought dominated, we find the traditional religious conceptions of these masters asserting themselves, modified by the tendencies of Christianity, and giving rise in the early period to the ontological realism of Anselm, and in the later to the theism of St. Thomas, which, while it is still realistic, is dominated by the cosmological conceptions of Aristotle. The whole theistic development of the middle ages is marked rather by an attempt to thoroughly digest and organize given elements, than by any decided advance in theistic conceptions. Cf. *PATRISTIC PHILOSOPHY, and St. THOMAS (philosophy of)*.

Modern philosophy, beginning with Descartes and setting out from the doctrine of substance, developed, in its religious conceptions, in the direction of a pantheistic naturalism which culminated in the system of Spinoza. This led to a reaction which, beginning with the individualistic system of Leibnitz, culminated in the deistic theology of the 18th century, the term deistical theology being used here to designate not simply the work of the deists proper, but also that of the

natural theologians and Christian apologists of the time. The reaction from pantheism led in general to an over-emphasis of God's distinction from the world, and to mechanical conceptions of his relations to man and nature. The deistical movement closed with the criticism of Kant, which showed the necessity for profounder conceptions, and led, on the one hand, to the speculative theism of the Hegelian school; on the other, to the negations of agnosticism and the phenomenalism of the school of Ritschl. Speculative theism is frankly metaphysical, and identifies God with the absolute ground of being; while the opposing school, following the letter of Kant, seeks to divorce religious thought from all metaphysical and transcendental presuppositions. Cf. DEISM, IDEALISM, and RITSCHLIANISM.

The latest stage of the theistic development is associated with the doctrine of evolution, which seeks the whole causality of the world in an immanent process, and thus tends towards a species of naturalistic pantheism in its religious conceptions. This has been the dominating tendency, at least in the last decades of the 19th century, though there are not lacking at present signs of a reaction towards a point of view in which greater stress is placed on the divine transcendence. It would seem that in this regard there is no middle ground between conceiving God as a being who is something in himself apart from the world, and reducing his idea to that of a mere abstraction from, or generalization of, natural laws or processes.

In connection with the development of theism the most important problems have been those of the existence of God and his relation to the world. The former has led to the development of the theistic proofs, a topic that can be only very briefly handled here. Kant has classified the proofs employed up to his time under three heads: the *ontological*, founded on the idea of God in the human consciousness; the *cosmological*, which, as he conceives it, is an inference from the contingency of the finite to the existence of a necessary non-finite being; and, lastly, the *physico-theological* or *teleological*, which is an inference from the order and adaptation in nature to some final cause or purpose as its ground. Kant himself was dissatisfied with these proofs, and proposed the *moral argument*, founded on the infinite demands of man's moral nature, as the only adequate ground of belief in God. The history of the proofs may be divided into two periods: (1) the pre-

Kantian, in which they were separately and somewhat uncritically developed; (2) the post-Kantian, in which, as a result of the trenchant criticism of Kant (anticipated also by Hume), the necessity of profounder treatment was recognized and religious thinkers began an attempt to unify the various lines of evidence, and to incorporate theism more completely with general philosophical principles of world-interpretation. The question of God's relation to the world has had a corresponding history. The somewhat shallow deism of the pre-Kantian period has given way to profounder views. It is no longer possible to conceive the same relation either mechanically or one-sidedly under the notion of transcendence. Assuming the immanent agency of God in the world, the alternatives open to the contemporary thinker are either pantheism, which frankly identifies God with the world, or a theistic conception in which a synthesis is aimed at between the notions of an immanent world-principle and a being that in its essential nature transcends the world of manifestation.

Contemporary theistic discussion presents three phases which can be but very briefly noticed: the *psychological*, the *epistemological*, and the *metaphysical*. The central question on the psychological side is that of the rise and meaning of the idea of God in the human consciousness. It is not overstating, I think, here to say that the trend of present thought is towards a view which may be stated in the proposition that the idea of God is natural to man, and that it takes its rise in social soil; that, in short, it is man as a *socius* who becomes a religious being. Cf. RELIGION (psychology of).

The epistemological question is that of the criticism of the idea of God as involved in the processes of human knowledge. Agnosticism, planting itself on the ground that the knowledge-process is finite and conditional, denies the possibility of conceiving a being that is infinite and absolute. It concludes either that God is unknowable, or that he is to be identified with the finite world of nature or humanity. In opposition to this we find a revival in contemporary thought of the old Augustinian contention that the very existence and possibility of truth and error in the finite sphere of human knowledge is founded on the necessary presupposition of an absolute ground of truth; in short, that the possibility of any knowledge involves *omniscience* as its condition. It is but another form of this conten-

tion to maintain that an infinite and absolute—that is, an ideally complete—experience is the necessary presupposition of an experience that is finite and fragmentary.

In the metaphysical field the principal questions under debate are (1) that of the relation of the concepts of religion to metaphysical principles. On the one hand, the phenomenologists or religious positivists, following the letter of Kant and denying the possibility of metaphysics, seek to construct a theism that shall rest exclusively on the evolution of humanity as a historic phenomenon. On the other hand, the sufficiency of this is denied, and it is contended that for an adequate basis of theism the notion of humanity must be related to that of an infinite and absolute ground; that otherwise the whole structure of religious knowledge is not secure against scepticism. (2) The second problem arises in the sphere of speculative theism, and concerns especially the relation of God to the finite individual. Assuming that God is the only absolutely real being, the problem is to find in his relation to the world an adequate ground of finite individuality. The older form of speculative theism attempted to conceive God's relation to the world under the categories of pure thought, and as a consequence found it difficult to vindicate any ground of reality for the individual. This difficulty has led to a profound modification of the position, by the incorporation of the categories of *will* and *feeling* into the very constitution of the absolute. God is thus brought not alone into conceptual, but also into volitional and emotional relations with his creatures. The world thus becomes the object of the divine purpose and love, and, inasmuch as these are *selective*, the individual finds a ground of reality or real justification in his relation to the absolute.

If now, going a step further, we represent the objective activities of the absolute as individuating in their very form and essence, so that no other than an individual result is to be expected, and if we connect this with the notion of the absolute stability and persistence of the divine activity, it would seem that we were in sight of a theistic conception in which it is possible to effect a synthesis between the notion of God as absolute reality and that of a perdurable finite individual possessing the reality of a moral agent.

Thema [Gr. *θέμα*, a deposit, dépôt, stakes, theme]; Ger. *Thema*; Fr. *thème*; Ital. *tema*. A word proposed in 1635 by Burgersdicius in his *Logic* (I. ii. § 1), for that 'quod intellectui cognoscendum proponi potest'; but what he seems to mean is what Aristotle sometimes vaguely expresses by *λόγος*, the immediate object of a thought, a meaning.

It is of the nature of a sign, and in particular of a sign which is rendered significant by a character which lies in the fact that it will be interpreted as a sign. Of course, nothing is a sign unless it is interpreted as a sign; but the character which causes it to be interpreted as referring to its object may be one which might belong to it irrespective of its object and though that object had never existed, or it may be in a relation to its object which it would have just the same whether it were interpreted as a sign or not. But the *thema* of Burgersdicius seems to be a sign which, like a word, is connected with its object by a convention that it shall be so understood, or else by a natural instinct or intellectual act which takes it as a representative

of its object without any action necessarily taking place which should establish a factual connection between sign and object. If this was the meaning of Burgersdicius, his *thema* is the same as the present writer's 'symbol' (see SIGN). (C.S.P.)

Theocracy [Gr. Θεός, God, + κράτος, government]: Ger. *Theokratie*; Fr. *théocratie*; Ital. *teocrazia*. Government by a god or gods.

The first known government, even when patriarchal, was theocratic. The most highly developed was perhaps the Jewish. The Mohammedan governments and the government (till lately) of the Papal States may be taken as modern instances. Theocracy is not involved in the mere recognition (as in classical Greece) of a divine power or powers over and above the political heads of the nation. In a theocracy the divine power, through his representative (the priests) or his word (e.g. the Koran), takes part in the actual political government. It is not enough for the ruler (as in ancient Rome) to be sometimes also the priest; in a theocracy it is the priest who is the ruler. (J.B.)

Theocrasy [Gr. Θεός, God, + κράσις, mixing, a mingling with the divine]: Ger. *innige Verbindung mit Gott*; Fr. *absorption en Dieu*; Ital. *teocrasia*. That state of mystical blessedness attained by the Neo-Platonic or Hindu theosophist when by ascetic preparation and contemplation he overcomes the barrier which separates his individual consciousness from the Absolute One and loses himself in the divine essence.

The state here defined is not an exclusive possession of Neo-Platonists and Hindu mystics; it is in some sense the ideal of all mysticism. It is the tendency of the mystic to escape definition and distinction in the spheres of both thought and feeling. This presupposes a distinctionless unity as its goal, which, emotionally contemplated, is the mystic's ideal of heaven. (A.T.O.)

Theodicy [Gr. Θεός, God, + δίκη, justice]: Ger. *Theodicee*; Fr. *théodicée*; Ital. *teodicea*. A department of theology or philosophy which has for its aim the vindication of the goodness and justice of God in view of the existence of evil in the world; or, more technically, that department of theology or philosophy of religion which treats of the nature and government of God and the destiny of the soul.

Although many theodicies were developed before Leibnitz, he was the first to employ the name distinctively in his *Essais de Théodicée*, which appeared in 1710, since which

the term has been in common use. The central issue in theodicies is the problem of evil in view of which the two opposing views of optimism and pessimism have been reached: the latter is the despair of its solution, and has received its classical utterance in Schopenhauer. The easy optimism of Leibnitz is no longer in vogue, and recent thought is pretty well divided between pessimism and the Kanto-Lotzian tendency to seek refuge in the demands of the moral judgment.

Literature: LEIBNITZ, *Essais de Théodicée*; WERDERMANN, *Neuer Versuch zur Theodicee* (1848); BENEDICT, *Theodicaea* (1882); J. YOUNG, *Evil and Good* (1861); SCHOPENHAUER and LOTZE, *Philosophies of Religion*; ROYCE, *The Conception of God*; and *Studies in Good and Evil*. See also RELIGION (philosophy of). (A.T.O.)

Theogony: see MYTHOLOGY.

Theological Ethics: Ger. *theologische Ethik*; Fr. *éthique théologique*; Ital. *etica teologica*. ETHICS (Christian). Ethics treated as a department of moral theology, and proceeding on the assumption of the absolute authority of Scriptures.

Literature: see ETHICS (Christian), and MORAL THEOLOGY. (A.T.O.)

Theology [Gr. Θεός, God, + λόγος, word or science]: Ger. *Theologie*; Fr. *théologie*; Ital. *teologia*. That part of the philosophy of religion which treats systematically of the Deity, his nature, attributes, and relations, and the grounds and limits of our knowledge of him.

Biblical theology: the systematic treatment of the doctrines of the Christian religion as contained in the Bible and developed in the history of the Church.

In the general sense, theology is a department of general philosophy. Biblical theology arises out of the application of principles of rational construction to the content of Christian revelation. Biblical theology is ordinarily divided into four branches—exegetical, historical, systematical, and practical or moral.

Literature: BELLARMINE, *Disputationes de controversiis fidei*; F. W. H. J. GASS, *Gesch. d. protestantischen Dogmatik*; Church Histories in general; HAGENBACH, *Hist. of Doctrines* (Eng. trans. by H. B. Smith); Herzog's *Real-Encyc.*; also Schaff-Herzog's *Encyclopedia*; Metzger and Welte's *Kirchenlexicon*; McClintock and Strong's *Encyclopedia*; systematic theologies, by HODGE, SHEDD, &c. (A.T.O.)

Theology (dogmatic): Ger. *dogmatische Theologie*; Fr. *théologie dogmatique*; Ital.

teologia dommatica. The system of theological doctrine developed dogmatically; that is, by a method whose ultimate appeal is not to reason, but to authority, either that of Scripture or of Scripture and tradition combined.

The basis of dogmatics in the Roman Catholic Church is a union of Scripture and tradition, while in the reformed churches, as a rule, the authority of tradition is rejected, and the dogma rests on the sole authority of Scriptures.

Literature: see THEOLOGY. (A.T.O.)

Theophany [Gr. Θεός, God, + φαίνεσθαι, to appear]: Ger. *Theophanie*; Fr. *théophanie*; Ital. *teofania*. (1) General: the revelation of himself which the Deity makes through his works.

(2) Special: God's revelation of himself in Christophanic form: in the Old Testament, in the Shechinah; in the New, in the incarnation, birth, baptism, and second coming of Christ. See CHRISTOPHANY.

In the general sense, the whole world may be regarded as a theophany or manifestation of the divine. In the special sense, God always appears in the person of the Son. (A.T.O.)

Theophrastus of Eresus. (cir. 370-288 B.C.) A Greek philosopher, pupil of Aristotle, for thirty-five years head of the Peripatetic School after the latter's death. See PERIPATETICS.

Theorem [Gr. θεώρημα]: Ger. *Theorem*, *Lehrsatz*; Fr. *théorème*; Ital. *teorema*. A demonstrable theoretical proposition. (C.S.P.)

Theory (in science) [Gr. θεωρία, a contemplation, speculation]: Ger. *Theorie*; Fr. *théorie*; Ital. *teoria*. A general principle or formula propounded for the purpose of explaining phenomena, as the 'theory of gravitation,' or the Newtonian theory.

In modern nomenclature it is confined to principles the truth of which has at least a large measurement of plausibility, in contradistinction to a hypothesis, which is propounded as a tentative explanation, the truth of which is to be verified or disproved by subsequent research. (S.N.)

The whole aim of science is to find out facts, and to work out a satisfactory theory of them. Still, a theory does not necessarily lose its utility by not being altogether true. It must be intelligible and diagrammatical, or it has no title to the name *theory*. The facts to which it refers are not necessarily facts of experience; they may be relations of pure mathematical forms. A theory is properly a result of systematic scientific con-

sideration, not of mere casual suggestions; and thus the word bears a somewhat eulogistic implication in contrast to 'view.' Theory is opposed to fact; the latter meaning, in this connection, that which is forced upon us by perception; while theory is the part of science which is contributed by the intellect and confirmed by experiment. Theory is also opposed to practice; because a theory is a scientific product, and a pure, or theoretical, theory has regard to science alone, and is often in conflict with the practical theory, which ought preferably to be the guide of immediate action. But the latter is as truly a theory as the former, and ought equally (when practicable) to be a product of scientific examination. That which science recommends for its own use in a secular investigation may be different from what it prescribes as a basis for instant action.

Every theory has its beginning in hypothesis. For, except perhaps in pure mathematics, the presumptive adoption of a hypothesis is the only possible way of framing a judgment concerning things beyond perception; unless we consider instinctive judgments as an exception. Neither is the situation essentially otherwise in pure mathematics. A mathematical theory supposes a broad conception of the forms to which it relates. This is known to be true of them only by a process of demonstration, which in many cases has to wait for several years for its accomplishment, and in all cases must be subsequent to the first beginnings of the theory. It may be that a quasi-induction has created a belief in a mathematical theorem before it has been demonstrated. But a valid and genuine induction is not possible in pure mathematics, for the reason that genuine induction essentially relates to the ratio of frequency of a specific phenomenon to a generic phenomenon in the ordinary course of experience. Now in pure mathematics, which deals with figments of our own creation, there is nothing at all to correspond accurately to a course of experience. Suppose we find, for example, that in a complicated development there is a certain regular relation among the first terms. If there is no obscure demonstrative insight which assures us that this *must* be, it is quite possible that, as the series goes on, a state of things may intervene which interferes with that relation, and if so, the proportion of terms that will accord with that formula will presumably be very far from 1:1. There is, therefore, no security of the nature which belongs to induction, that as the instances

are multiplied the observed ratio will indefinitely approximate to the true ratio. This sort of induction, therefore, has no other validity than such as belongs to a hypothesis which suits the facts as far as we yet know them. If it is to be called an induction, it is a degenerate induction differing very little from hypothesis. It may properly be said, then, that even a pure mathematical theory is developed out of hypotheses.

No theory in the positive sciences can be supposed to satisfy every feature of the facts. Although we know that the law of gravitation is one of the most perfect of theories, yet still, if bodies were to attract one another inversely as a power of the distance whose exponent were not 2, but 2.000001, the only observable effect would be a very slow rotation of the line of apsides of each planet. Now the lines of apsides all do rotate in consequence of perturbations, which virtually do alter slightly the sun's attraction, and thus such an effect would probably only produce slight discrepancies in the values obtained for the masses of the planets. In very many cases, especially in practical problems, we deliberately go upon theories which we know are not exactly true, but which have the advantage of a simplicity which enables us to deduce their consequences. This is true of almost every theory used by engineers of all kinds. The most extraordinary departure from the known facts occurs when hydrodynamics is applied, where the theory is in striking opposition to facts which obtrude themselves upon every spectator of moving water. Nevertheless, even in this case, the theory is not useless.

In all the explanatory sciences theories far more simple than the real facts are of the utmost service in enabling us to analyse the phenomena, and it may truly be said that physics could not possibly deal even with its relatively simple facts without such analytic procedure. Thus, the kinetical theory of gases, when first propounded, was obliged to assume that all the molecules were elastic spheres, which nobody could believe to be true. If this is necessary even in physics, it is far more indispensable in every other science, and most of all in the moral sciences, such as political economy. Here the same method is to begin by considering persons placed in situations of extreme simplicity, in the utmost contrast to those of all human society, and animated by motives and by reasoning powers equally unlike those of real men. Nevertheless, in this way alone can a base be obtained

from which to proceed to the consideration of the effects of different complications. Owing to the necessity of making theories far more simple than the real facts, we are obliged to be cautious in accepting any extreme consequences of them, and to be also upon our guard against apparent refutations of them based upon such extreme consequences.

Whewell makes a great point of the relativity of the distinction between theory and fact. This is an important point that ought not to be overlooked. Every fact involves an element supplied by the mind, which if not, properly speaking, theory, is analogous to theory. On the other hand, serious errors of logic will result from not taking account of the difference between the intellectual elements already involved in the perceptual facts and scientific theories. A theory is a result subject to criticism, meaning by criticism, not the consideration of whether or how far an object is beautiful, useful, or the like, but the passing of a judgment as to whether the object *ought* to be as it is or as it is proposed to make it. If this judgment is adverse, the theory can and will be altered; and it will not be maintained by anybody until it is put into a shape to withstand his criticism. But it is perfectly idle, in this sense of the word, for anybody to criticize what he cannot help; and, like other idle and unamiable practices, it is also highly pernicious. Now all the subconscious work of the intellect in framing a percept and a perceptual judgment is beyond our control, and therefore not subject to logical criticism. It simply has to be accepted. Kant, perhaps, did not sufficiently appreciate this when he undertook to study the critic of such mental forms as space, time, unity, reality, &c.; but, after all, his deduction of the categories is merely in outcome that knowledge cannot be had on other terms; that is, that they are inevitable. Perceptual judgments, therefore, are, for the purposes of logical criticism, absolute facts without any admixture of theory. If a theory does not square with perceptual facts it must be changed. But the impressions of sense from which it is supposed that the percepts have been constructed are matters of theory. If the percepts were proved not to square with the impressions of sense, it would not at all be the percepts that would have to be reformed, for they cannot be reformed; it would be, on the contrary, that theory, that the percepts are constructed out of impressions of sense, that would have to be modified. (C.S.P., C.L.F.)

Theory of Knowledge: see EPISTEMOLOGY, and cf. GNOSIOLOGY, PHILOSOPHY, and METAPHYSICS.

Theosophy [Gr. *θεοσοφία*, divine wisdom]: Ger. *Theosophie*; Fr. *théosophie*; Ital. *teosofia*. (1) A stage into which philosophic reflection passes when its primary data are God and an organ through which he is revealed or mystically intuited.

(2) A form of Buddhistic thinking which from the postulate of a divine principle deduces the fundamental law of things, a vibratory movement of evolution and involution, the application of which in the sphere of psychic life leads to the process of perpetual reincarnation.

In the first or general sense most oriental thinking is theosophic. Modern thought first became distinctively so in Neo-Platonism, but the tendency has survived down to the present, and has taken on various embodiments.

The Buddhistic form is a direct importation from the East, and has Madame Blavatsky for its great apostle. It has many votaries, and seems to be a growing cult. Cf. MYSTICISM.

Literature: PLOTINUS, *Enneads*; PSEUDO-DIONYSIUS, *Theologica mystica* and *De divinis Nominibus*; works of JACOB BÖHME and SWEDENBORG. For the special forms, see Johnson's *Cyclopedia*, art. Theosophy; WM. Q. JUDGE, *The Ocean of Theosophy* (1893); SINNETT, *Esoteric Buddhism* (1883); RAMA PRASAD, *Nature's Finer Forces* (1890). (A.T.O.)

Therapeutics (mental): see PSYCHOTHERAPEUTICS, and MIND-CURE.

Thesis [Gr. *θέσις*, a placing or setting; also, in the modern sense, and apparently sometimes to mean merely a universal proposition]: Ger. *These*; Fr. *thèse*; Ital. *tesi*. An assertion formally stated preparatory to a regular defence of it by argumentation.

The Latin form *positio* is less formal in its implication. The denial of a thesis preparatory to regular counter-argumentation is sometimes called the *antithesis*; but this is rarely used except with reference to Kant's antinomies. In geometry, the abstract statement of a theorem is called the *enunciation*, or first enunciation; the statement with reference to the diagram being called the second enunciation, or statement. The latter is also called the *ecthesis*, or *exposition*. For other meanings of thesis, see *The Century Dictionary*. (C.S.P.)

Thing (in law): Ger. *Ding*, *Sache*; Fr. *chose*; Ital. *cosa*. The object of a RIGHT (q.v., in law).

It must be something capable of standing in a relation to the human will; it may be either material, or an object or group of objects only discernible by the mind (Holland, *Jurisprudence*, chap. viii. 85). *Simple thing*: one that can be comprehended, externally, by a single act of recognition, e.g. a horse. *Compound thing*: one to be comprehended only on a view of its several acts or properties, separately considered, e.g. a house. *Intellectual things*: those not material, e.g. an obligation, a copyright. *Divisible things*: things divisible without destroying their essential character or value. A house or horse cannot be thus divided; a pair of horses or block of houses might be (see Pollock, *Jurisprudence*, chap. vi). *Thing in action*, or *chose in action*: a thing not in the possession of the person with reference to its relation to whom it is considered. Not being in his possession, he, if the owner, may be forced to bring an action in order to get it. *Things fungible*: those which can be replaced by others of the same kind without loss to the owner, e.g. a barrel of flour of a certain brand. See RES. (S.E.B.)

Thing-in-itself: see NOUMENON, DING AN SICH, and KANT'S TERMINOLOGY, Glossary, 'Ding an sich.'

Thinking: see THOUGHT.

Thinking (in educational method). In general, the exercise of the intellect, specifically, in grasping the significance of facts presented in instruction.

Nearly all stages of school methods give the pupil's mind some exercise in thinking, but the phase of thinking deemed important enough to be designated as a stage or 'step' in method is the formation of generalizations. Dörpfeldt classifies the mental movements formed in a complete act of learning as follows: (1) Observation, (2) Thinking, (3) Application. Other writers, like Ziller and Rein, divide this second stage into Association and Generalization. See FORMAL STEPS, REFLECTION, and METHOD (in education). (C.D.E.)

Thisness [ME. *this*]: Ger. *Diesheit* (Wolff); Fr. *eccéité*; Ital. *ecceità*. Trans. of Lat. *haecceitas*. See LATIN AND SCHOLASTIC TERMINOLOGY, II, and cf. Eisler, *Wörterb. d. philos. Begriffe*, 'Haecceitas.' (J.M.B.)

Thomas à Kempis. (1380-1471.) Born at Kempen, near Cologne; was for seven years novitiate; entered, about 1407, the cloister of St. Agnes as regular canon, became superior, and died there. He belonged to the Brotherhood of the Common Life, founded by Ruysbroek and Geert de Groot.

Thomas Aquinas : see AQUINAS, THOMAS, THOMISM, and ST. THOMAS (philosophy of).

Thomasius, Christian. (1655-1728.) Education completed at Frankfurt-on-the-Oder; travelled in Holland; professor of law at Leipzig, 1681; one of the founders of the University of Halle; professor of law there, 1698. Died at Halle. He was the first to introduce German as medium of university instruction; supported Spener and his school of pietists; was hostile to all pure speculation, and made notable innovations as a jurist.

Thomism : Ger. *Lehre des Thomas von Aquino*; Fr. *le Thomisme*; Ital. *il Tomismo*. The principles of St. Thomas Aquinas and his followers, who combined with certain doctrinal views belief in the ultimate harmony of reason and faith, and of the conclusions of philosophy with those of theology.

The doctrinal views held were unconditional predestination and efficacious grace, combined with conditional freedom of the will; physical as well as moral efficacy of the sacraments; and the denial of the Immaculate Conception. See SCHOOLMEN, and ST. THOMAS (philosophy of).

In the Thomistic unification of faith and reason, theology and philosophy, the ideal of scholasticism is practically realized. Doctrinally, St. Thomas is a mediating thinker, and embodies a moderating intelligence, which in general strikes the golden mean in Roman Catholic conviction and tendency. He is consequently the canonized thinker of the Church. (A.T.O.)

The Thomists were originally called Albertists, after the teacher of St. Thomas, ALBERTUS MAGNUS (q. v.). At first the Dominican Order took St. Thomas for their official philosopher. It was opposed by the Franciscan, which followed Alexander and Bonaventura. As the Nominalists were opposed to Thomism, and as the former came under the ban of the Church, there was a growing tendency for Thomism to become more and more the orthodox philosophy of the Church. It has received a notable revival in our own generation from the peculiar interest taken in it by Pope Leo XIII. (J.D.)

Literature : MIGNÉ, *Patrology*, Supplement; THOMAS HARPER, *The Metaphysics of the School* (1877); also UEBERWEG's and ERDMANN's *Histories of Philosophy*. An excellent history of Thomism is contained in the third and concluding volume of K. WERNER, *Der heilige Thomas von Aquino*. (A.T.O.)

Thought : Ger. (*das*) *Denken*; Fr. *pensée*;

Ital. *pensiero*. (1) All cognition of objects other than sense-perception.

(2) The word is sometimes used as equivalent to conceptual process as such.

A train of thought consists of successive thoughts referring to the same object and determined by a single continuous interest centring in this object.

The thought function, considered as conceptual process, is usually treated as covering CONCEPTION, JUDGMENT, and REASONING, in the textbooks (see those topics for more extended matter). (G.F.S., J.M.B.)

Thought Reading. Another word for MUSCLE READING (q. v.).

Thought Transference : Ger. *Gedankenübertragung*; Fr. *transmission de pensée*; Ital. *trasmissione del pensiero*. See TELEPATHY, and cf. MUSCLE READING.

Threshold [AS. *therswald*]: Ger. (*Reiz-, Empfindungs-*) *Schwelle*; Fr. *seuil*; Ital. *soglia*. LIMEN (q. v., also for foreign equivalents). Cf. LIMITS (of sensation and stimulus).

The term 'threshold' is sometimes applied to the stimulus, sometimes to the sensation. It was first used by Herbart and was given its present signification by Fechner. (J.M.C.C.)

The conception of threshold has been used in psychophysics (see PSYCHOPHYSICAL METHODS). The experimental threshold has been found to vary for various sorts of stimulation: (1) with the method of approach from above or from below, (2) with the direction of attention (distraction), (3) with the degree of fatigue; and to be influenced by conditions of relative summation and inhibition.

The least noticeable DIFFERENCE (q. v.) in sensation is called the threshold of discrimination or difference (*Unterschiedsschwelle*).

Literature : that of PSYCHOPHYSICS (q. v.) and PAIN (q. v.). (J.M.B.)

Tic [Fr.]: Ger. *Tic*; Fr. *tic*; Ital. *tic, ticchio*. A peculiarity or idiosyncrasy, particularly of motor form; applied specifically to movements of twitching.

Peculiar mannerisms of hemming or hawing in speech, of twitching a muscle, stroking the chin, rubbing the hands, clenching the teeth, tapping with the foot are as a rule quite within the range of the normal, although they are apt to be marked in neurotic individuals. At times, however, these tics are so peculiar and so removed from voluntary control as to constitute an abnormality. Such a patient may feel an irresistible impulse to interrupt his speech with an animal-like noise, to interject obscene expressions (coprolalia), to imi-

tate all that is heard (echolalia), or to mimic the movements of others (echokinesis), and so on. These impulses are closely allied to the working of the IMPERATIVE IDEA (q. v.). The intelligence is not affected, and at times intense effort may overcome the morbid tic; but it is often a chronic and incurable disorder.

Irresistible motor habits are termed convulsive tics, and the others psychic tics; while the more elaborate ones are termed co-ordinated tics.

Tic douloureux is an acute NEURALGIA (q. v.) of the trigeminal or facial (fifth cranial) nerve.

Literature: NOIR, *Étude sur les tics* (1893). (J.J.)

Tickle Sensation [ME. *tiklen*]: Ger. *Kitzel*; Fr. *chatouillement*; Ital. *solletico*, *formicolio*. A TOUCH SENSATION (q. v.), whose conditions are still obscure.

Tickling possibly includes a peculiar organic quality derived from the unstriped muscles that lie directly beneath the skin, and possibly a circulatory quality (tingling and itching: see ORGANIC SENSATION). Probably the muscular movement is wholly reflex, and the sense components in tickling are simply those of light and intermittent touches and temperatures, with which visual or other associations are conjoined. The muscular reaction of laughter is intimately bound up with the sensation.

Besides the well-localized tickle proper, described above, there is a sensation-complex, from rubbing and moulding the skin and muscles, especially in certain regions (e.g. the neck), which has very analogous, but more massive, reflex effects. This is also called 'tickling,' and is made use of in the games of children. It has never been analysed.

Literature: KÜLPE, *Outlines of Psychol.*, 89, 147, 250; SANFORD, *Course in Exper. Psychol.*, expt. 31; HALL and ALLIN, *The Psychol. of Tickling*, &c., *Amer. J. of Psychol.*, ix. 1897, 1. (E.B.T.-J.M.B.)

Tiedemann, Dietrich. (1748-1803.) Born at Bremervörde and educated at Göttingen. In 1776 he became a teacher of ancient languages at the Collegium Carolinum in Cassel, in 1786 professor of philosophy and the Greek language at Marburg, where he died.

Tilt-board: see LABORATORY AND APPARATUS, III, B (c), (3).

Timbre: [Lat. *tympanum*, a drum, through Fr.]: Ger. *Klangfarbe*; Fr. *timbre*; Ital. *timbro*. The complex of overtones and noise

that accompanies the FUNDAMENTAL TONE (q. v.) of a musical note.

It varies with the instrument, and thus enables us to recognize the source of the sound, as piano, harp, &c. It is sometimes termed clang-tint or quality (Helmholtz, Eng. trans., as below, Index, 'Quality') of a musical tone. It would seem better, however, to reserve the term quality for PITCH (q. v.).

Literature: HELMHOLTZ, *Sensations of Tone*, 119; SANFORD, *Course in Exper. Psychol.*, expt. 90; TITCHENER, *Exper. Psychol.* (1901), expt. 8. (E.B.T.-J.M.B.)

Time [Lat. *tempus*; Gr. *χρόνος*]: Ger. *Zeit*; Fr. *temps*; Ital. *tempo*. The measurable form of continuity and externality of parts in all real (empirical) process. Time is constituted of the complex of relations of duration and succession in the experienced order of events. See SUCCESSION AND DURATION, and cf. CHANGE.

Time may be variously conceived, according to the point of view, as the order or arrangement of existences in these relations, as quantity or 'number' of changes relative to order of succession, and, again, as the ideal 'place' or medium in which these relations of duration and succession are found. These conceptions are general, applicable to an indefinite number of instances. But all times are commonly considered to be parts of one unlimited time. This one single time, however, is neither an individual conception nor an 'intuition,' but an object to which the general conception of time is applicable in a special way. There is no 'intuition,' i. e. perception, of 'pure' time, and the only way of representing it which is at all clear is by the imaginary synthesis of moving points or lines in space.

All accounts of time agree in connecting it with change. A changeless content, like a mathematical relation or a Platonic idea or, in general, valid meaning or truth, is not in time. But though change is essential to time, time is not the mere qualitative form of change. Nor is it mere succession or the mere abstract relation of succession. For succession to be temporal a relation of the terms is required such as to form a continuous and measurable series. The abstraction from the content of the relation of before and after in the continuity of a measurable process is temporal succession. The abstraction from the content of the total form of such a successive, continuous, and measurable process is time. Time is thus both continuous and

discrete, continuous as quantity, discrete as a measurable quantity divided into intervals of days, months, years, &c. These intervals designate and measure temporal duration. Duration, thus considered, consists in immanent measures and divisions of time. But since time is continuous as well as discrete, all time-intervals may be regarded as parts of one infinite whole of duration. The relation of time to duration may then be viewed in another way: time may be regarded as the process of the successive measuring of this whole. Since, however, the parts of time are only and always successive, a duration supposed to precede the succession would not be temporal. Time cannot be properly identified with a duration of this sort. The popular identification of time and duration merely implies, perhaps, a special emphasis on one of time's aspects.

Subjectively, each individual constructs his own time-order from the standpoint of the 'specious' or felt present by means of images in which past and future, not actually present, are represented. It is only from this standpoint that the terms past and future have proper meaning. In this construction are included not only the times of the individual's private experiences, but all times which may be dated from the present 'now.' Abstracting from the subject and viewing the constructed order objectively, we think time as uniformly successive in its parts and homogeneous throughout its entire length, wherein every 'when' is a 'now,' relative to the general determinations of before and after. This uniform and homogeneous order is further thought as endless and infinitely divisible. It is endless because every 'now' is relative to a before and also to an after; it is infinitely divisible as abstract continuous quantity. From the standpoint of actual experience, time is probably finite in both respects.

We have no definite standard for the measurement of time subjectively. We measure time, whether regarded from the subjective or the objective point of view, objectively on the basis of a comparison of independent series of rhythmic movements. No time-unit, accordingly, would seem to have any absolute length. If so, then one time is not separated from another time by any absolute interval. Time, as thus objectively measured, is time viewed physically, the time of objective physical happenings and of subjective processes looked at from the outside. But other orders of time are conceivable and, indeed, in a sense, actual.

Such, for example, is the time of dreams, of works of imagination like an epic or a play; such, too, is absolute or mathematical time. An indefinite number of independent temporal series may thus conceivably coexist. Our idea of the time-order of the physical world—indeed, our specific idea of time generally—depends on the empirical fact of regularly recurring series and on our peculiar way of appreciating such series. It is doubtful, therefore, whether other ideas of time might not have been developed, or may not, in other orders of intelligent existence. And even with the same order of time considered abstractly there is perhaps no contradiction in thinking an entire reversal in the order of the content.

The abstract conception of time is full of difficulties and contradictions. Succession and duration are both essential, yet each, for itself considered, negates the other. In its uninterrupted succession time has no standing, but 'flows,' yet all succession is conceived of as being 'in' time as a sort of unity. But in time itself no unity is discoverable; the mere relation of before and after cannot constitute such a unity, and in the parts of time there is no least part which is not capable of being resolved into relations of this sort endlessly. The fleeting aspect of time early gave rise to the question of its reality. The past, it was said, is not, being past, and the future is not yet; hence time is never actual in any of its parts, for the momentary 'now,' taken strictly, is no part of time, but a limit, the beginning or end of a period. The successive, indivisible 'nows' afford a further difficulty. They cannot be conceived of as all the same, for it is essential to time that there should be an earlier and a later 'now.' But, on the other hand, it is not easy to see how the different 'nows' arise. Each, in vanishing, can neither give place to another immediately contiguous, for time is not like a sum or series of points, nor to one more remote, for the intermediate time is infinitely divisible; and it is still less possible that it should give place to itself. Ideally, in fact, there neither is nor can be a 'next' moment of time. Aristotle already notices most of the difficulties mentioned, and similar criticisms have been repeated and multiplied in all discussions of the subject since. Hegel gives perhaps the most forcible abstract expression of the inner contradictions of time when, in his own peculiar terminology, he describes it as 'die für sich seiende Negativität' (*Encyk.*, § 258).

The difficulties and contradictions in the

idea of time viewed objectively, i.e. in abstraction from the subject, and the obvious dependence of our actual time constructions on subjective processes, eventually led to a rehabilitation of the subject and to the production in the total stream of speculation of a steady and persistent current of opinion to the effect that time and temporal order have their sole being in and through such subjective constructions. This opinion is strengthened by the reflection that the content of all scientific, that is, true and complete, thinking is essentially timeless. Time may then be condemned as mere 'appearance' opposed to 'reality.' But the terms are ambiguous, and it is better to consider everything as real which is strictly taken for what it is and not taken for what it is not. The essence of the opinion above stated is that time depends on and derives its continuity, unity, and succession from the activity of a subject changelessly present in all its moments. But the subject is ambiguous: it may mean (a) the individual subject as opposed to the object, or (b) a principle of the subject as constitutive of objects. Either view is susceptible of modifications, each of which has its own special difficulties. Some of these will appear in the sketch of the history of opinion which follows.

History. Plotinus (*Enn.*, iii. 7. 7), in agreement with Aristotle (*Phys.*, iv. 10), says that time was commonly defined among the Greeks in three ways: (1) as motion, either (a) all motion, or (b) that of the celestial sphere; (2) as the moving sphere itself (an opinion attributed to Pythagoras, Diels, *Dox. gr.*, 318); (3) as a determination of motion, more particularly as (a) extent of motion (Stoics), or (b) number of motion (Aristotle), or (c) an accompaniment of motion generally (Epicurus). The only one of these so-called definitions that now interests us is that of Aristotle. Plotinus complains that none of them tells what time, in metaphysical reference, really is. This he himself attempts to do, following Plato. Aristotle's discussion of time is from the 'physical' point of view. The third important contribution to the subject in antiquity is made by St. Augustine, who formulates the subjectivistic-psychologic view. The development may be briefly traced in these three stages.

Aristotle predicates of time—he can hardly have meant the statement as a definition—that it is 'number of motion relative to before and after' (*ἀριθμὸς κινήσεως κατὰ τὸ πρότερον καὶ ὕστερον*, *Phys.*, iv. 11. 219 b 2). 'Number,'

he explains, means here not the subjective number with which we count, but what is numbered (b 7). Time, then, is something numbered, or containing internal distinctions that can be counted and summed, which determines motion considered with reference to the succession of its parts. Though Aristotle's term for motion (*κίνησις*) includes qualitative change as well as change of place, the ideas on which his representation of time is moulded are all suggested by the latter. The 'before' and 'after' of time rest primarily on the analogous distinctions of position in space, the 'here' and 'there' successively occupied by a moving body (a 14). The continuity of time is derived from the continuity of motion, which, in turn, depends on the continuity of corporeal extension. Magnitude, motion, and time all go together (a 8 f.). So pervasive are these conceptions that Aristotle does not hesitate to speak of time as the number of the local movement (*φωρά*) in which the 'now' is, as it were, borne along, like a moving point in space, as the generating unit (*μονὰς τοῦ ἀπθροῦ*, 220 a 3). Thus he holds that the 'now' is in one sense always the same, while in another, as occupying different positions in the series, it is always different. In the identity of the 'now' he finds the ground of the self-identity of time taken as a whole, though relatively to motion time is always changing (219 b 10 f.). This purely objective, analogical view of time is obviously no solution of the problem. The identity and difference of the time-moments are certainly not given as objective facts. Nor are the contradictions involved in the conception of a being that never is, but is perpetually coming to be and perpetually passing out of being, removed by attaching time to motion. For Aristotle, the reality of time is coincident with that of motion; but motion is a conception which involves similar contradictions. From the purely objective point of view, these contradictions are unavoidable. But Aristotle suggests another point of view when he raises the question at the close of his discussion whether there would be any time if there were no such thing as soul. His reply is cautious, hypothetical. If, he says, nothing is capable of numbering but soul, and, indeed, intellect, then, if there were no soul, there would be no time, unless, e.g., motion is possible without soul (14. 223 a 16 f.). From the ordinary point of view, such is, of course, the fact, and in a 'physical' treatment of the subject Aristotle does not feel called on to transcend that

point of view. The problem finds its solution, if at all, in the wider context of his metaphysics, in which motion is brought into a relation with a prime mover, which is also Nous.

It is this metaphysical point of view which is prominent in the school of Plato. Plato himself treats of time (*Tim.*, 37 c-38 d) as a creation of the demiurge, 'a moving image of eternity' added to the world's other perfections that it might resemble as much as possible the eternal nature of the gods. This myth, though lacking in conceptual clearness, has at least the merit of definitely connecting time with an intelligent principle of existence whose mode of being, as Plato says, is not properly represented by diversity of sense. The Neo-Platonists are more explicit. Time, according to Plotinus (*Enn.*, iii. 7. 11)—and a similar deduction is found in Iamblichus (see Zeller, *Nacharistotel. Philos.*, 707)—is generated by the restless energy of the soul seeking to express in matter the infinite and eternal fullness of being. As it cannot do this at a stroke, it is forced to a successive series of acts. Time is this life of the soul, beheld and contained in it and subsisting with it, as, on the other hand, eternity is the life of intelligible being in its full, unbroken, absolutely unchangeable totality. In this view, which reappears in various modifications in the history of dynamic idealism (see e.g. Schelling, *Syst. d. tr. Ideal.*, Werke, i. 3. 465 f.), time is objective only because the object which it qualifies is subjectively determined; but subject and object are both embraced in a comprehensive unity which is timeless.

No one shows a keener appreciation of the contradictions involved in the purely objective view of time than St. Augustine (*Conf.*, xi). He believes, with Plato, that time is objective, it having been created by God with the creation of the world (*Civ. Dei*, xi. 5); but as to what it is, he confesses, 'si nemo a me quaerat, scio, si quaerenti explicari velim, nescio.' He is particularly disturbed by the fact that, while no part of it is, we yet measure it. The only solution of the paradox he can suggest is that time is present in and measured by the soul. There are not properly three times, a past which is not and a future which is not, with an intermediate present which is a mere point of transition between these two nonentities; but there is a present of things present, a present of things past, and a present of things future, the first in attention, the

second in memory, and the third in expectation. Time, in itself considered, he concludes, is nothing, and cannot be measured; it only seems to be and to be measured in present comparison and regard. The novelty of this view consists in transferring the reference of time from the world-soul to the human soul. Yet Augustine cannot rest permanently satisfied with this view, for he still continues to regard time as an objective, divinely created fact. The two views are here manifestly at strife, and Augustine contributes nothing to their reconciliation. His distinction is that he first definitely presents the subjectivistic view of time as existing only in the present regard of a comparing consciousness. How this view is consistent with the recognition of an objective temporal order of events, he does not show.

Most, if not all, of the questions and the points of view concerning time debated and developed in antiquity reappear in the middle ages. Here, too, time is commonly regarded as a relation or aspect of motion, the two, according to some (Duns Scotus, Suarez), being 'materially' identical and only 'formally' distinct. Even the view that time is 'mobile quod movetur' is represented (Occam). In spite of numerous objections (for which see Duns Scotus, *Op.*, ed. Vives, iii. 141), the formula of Aristotle, or its equivalent, is generally accepted as a definition. As against the Averroists, the orthodox schoolmen hold that time had a beginning, though neither Aquinas nor Scotus find convincing reasons for the doctrine apart from revelation (see Stöckl, *Philos. des Mittelalters*, 556 f., 836 f.). Characteristic are the discussions of the differences between time, eternity, and 'aevum,' the last an attribute of the heavenly bodies and the angels, eternity being predicated only of God. The best opinion (Aquinas, *Summa Theol.*, i. 10) was that eternity is a 'res tota simul' without the beginning, end, or succession essential to time and capable of being conjoined with, though not essential to, 'aevum.' A further distinction, likewise of theological import, is made between the physical time which measures the motions of the heavens and spiritual 'discrete' time, composed of the indivisible, successive instants of change in the intellections and volitions of the angels and measured by the thought of the supreme Angel (Suarez, *Op.*, ed. Vives, xxvi. 961). The difficulty with regard to the reality of time arising from the view of the instant as a durationless limit

dividing a non-existent past from a non-existent future is commonly met, on the principle 'esse successivorum est fieri,' by simply declaring the parts of time to be actually successive. Suarez, however, though seeming to regard this as satisfactory, incidentally suggests a profounder solution when he says that the successive parts of an action, and hence their real duration, may be conceived as a whole in a form which is non-successive (op. cit., 958 b). He also considers the idea of time as a sort of space flowing from eternity as purely imaginary, and the location of a given duration in this space as a purely mental act. There is no repugnancy, he contends, in supposing the real duration of a given motion, absolutely considered, as recurring (op. cit., 954). But the radical conception of time as a mental construction through and through, which these utterances suggest, he does not grasp. This conception, however, in the general form that time depends for its existence on the soul, was also represented, notably in the case of one Aureolus, and was regarded as sufficiently important to be condemned by the bishop and University of Paris and to be discussed at considerable length by the schoolmen. Among the arguments in its favour, as reported by Albertus Magnus (*Op.*, ed. Vives, iii. 310), is the rather acute observation that if, as commonly supposed, time were generated by the motion of the celestial sphere, all the parts of time would be together, since the heaven moves in all its parts at once. A not uncommon solution of the difficulty implied in the accepted Aristotelian formula was that while number, and hence time, could only exist in the mind 'in actu,' it existed outside the mind 'secundum potentiam'; Albertus adds, as a further ground for the existence of time 'in se ipso,' the 'habitualement formam discretionis,' which first makes the numbering of things possible (op. cit., 339). The conclusion that even for the objectively thinking schoolmen time was really a product of mental construction with an objective basis of validity is obvious.

The schoolmen distinguished time, to which succession was essential, and duration, to which, as applied, for example, to God and the angels, it was not. This distinction reappears in various forms in the early period of modern philosophy in connection with a subjectivistic, or at least idealistic, view of time, a view which steadily gains ground and definition in the course of modern speculation. For Descartes time, derived, as he held, from a com-

parison of the durations of certain regular motions, was simply a way of thinking of duration in general (*Pr. ph.*, i. 57). How little the close co-ordination of time and space, unknown to the ancients and so familiar to us, was yet established, appears in the contrast in Cartesian philosophy between time as subjective and independently existing extension. Spinoza defines time similarly (*Cog. met.*, i. 4): it is an imaginary representation wholly without ontological significance. Unlike the schoolmen, he limits duration to finite existence (*Cog. met.*, ii. 1); the eternity under which we think the infinite existence of God is, therefore, by no means to be regarded as a kind of quantity (*Eth.*, ii. 45). With Leibnitz the distinction between time and duration is capital. Everything has its own duration, but not its own time; the former is an attribute of things which the latter, as something outside things, serves to measure (*Ex. de Malebr.*, Erd., 692). Time is of the nature of the 'eternal verities,' applicable to the possible as well as to the actual, therefore not a mere abstraction from experience (*Novv. Ess.*, ii. 14). It appears thus as a sort of divine thought, an ideal rule or mode of connecting 'inconsistent possibilities,' independent of things as number is independent of the thing numbered (*Philos. Abh.*, Gerh., iv. 568). But Leibnitz does not further expound or explain this ideality of time, and elsewhere often speaks of 'time or duration' as an attribute of things themselves. This mode of speech gave rise to the traditional interpretation, according to which time is an obscure representation of a real attribute. It was currently defined in the school as 'ordo successivorum in serie continua' (Wolff, *Ont.*, § 572).

The classical expression of time's independent reality is found in Newton, who speaks of 'absolute, true, and mathematical time' as something which 'in itself and from its own nature flows equally, without relation to anything external,' and with no liability to change (*Princ. of Philos.*, v. 1). But the trend of British philosophy is also subjectivistic. This appears already in Hobbes' definition of time as 'phantasma motus quatenus in motu imaginamur prius et posterius, sive successionem' (*De Corp.*, vii. 3). According to Locke, however (*Essay*, ii. 14), the idea of time does not depend primarily on motion, but on succession of ideas and observation of distance in the parts of this succession. How succession of ideas gives rise to ideas of succession, and how

distance in its parts is observed, he does not explain. Moreover, his psychological analysis is hardly intended as a denial of the reality of absolute time, but rather presupposes it, limiting only our knowledge of it to its sensible measures. But in the context of an inquiry into the nature and limits of knowledge, where the relation of idea and object was everywhere confused, it readily lent itself to the more radical interpretation. Accordingly we find Berkeley, 'embrangled,' as he says, in inextricable difficulties when trying to think time in the abstract, declaring that time is nothing but the succession of ideas (*Pr. Kn.*, § 98; *Life*, 177), and in this he is followed by Hume (*Tr.*, Pt. II. sec. iii). Both writers, appealing to experience and refusing to recognize the reality of mere abstractions, deny that time is infinitely divisible, conceiving it rather as made up of discrete moments, each with the duration of a single idea¹. The general criticism of this view is that it implies the wholly fictitious representation of experience as made up of trains of discrete ideas. More particularly, successive impressions cannot of themselves account for the perception of succession. Successive impressions may be subjectively distinguished without consciousness of time at all. Conversely, a mental process without successively distinguished parts is found, when measured by objective standards, to occupy a time-interval of appreciable and theoretically divisible extent. It is true, there is a least amount of time which can be sensibly experienced, and the time of our empirical consciousness is so far free from the perplexities involved in the infinite divisibility of the time of our intellectual construction. But this construction may not simply be ignored. Finally, the character of time itself is not rightly apprehended, and cannot, therefore, be rightly accounted for when permanence and continuity are sacrificed to mere succession; and the latter, which is not time at all, but at best only in time, is made to do duty for the manifold of relations implied in the temporal order. On the other hand, Newton's conception of time is full of obscurities and contradictions. An absolute time with an independent flow would seem to require another time in which it flowed and by which its rate of flow was

measured, and so *in infinitum*. And the flowing of time, if literally taken, is quite unintelligible. Does it flow as a whole, or only in its parts? There is absurdity in either supposition. For if it flow as a whole, then as the whole of time includes both past and future, the latter must be always existent simultaneously. And the same is true if only the parts flow, for these are its parts. But does it flow at all? Why does it not rather 'stand' as the permanent medium for the flowing sequence of events? But this, too, is also impossible, if the purely objective view of time be taken; for the parts of time are successive. And there is the further difficulty about abstract time, that its parts are never together, and that there is no final term (cf. Lotze, *Met.*, 268 ff.).

In the Kantian doctrine that time is an *a priori* form of the inner sense, an intuition or form of intuition empirically real, i.e. valid, but transcendently ideal, i.e. with no significance for things-in-themselves (*Diss.*, § 14, *Krit. d. reinen Vernunft*, *Tr. Aesth.*, ii), the earlier view of time as a way of thinking is developed and defined. The principal objection to Hume's theory is here met by the implied presence, to the succession of impressions, of the unchanging synthetic unity of consciousness. Here at last we find the unity which Aristotle desiderates in the identity of the moving 'now.' Again, the difficulties in the mathematical conception of Newton disappear, or, at least, appear less formidable, when it is seen that the continuity, homogeneity, endlessness, and infinite divisibility it attributes to time belong, not to an independent entity, but merely to the way we represent the connection of process in the objects of our actual or ideally possible perception. And the doctrine has the further positive advantage of plausibly explaining the wide range of our universal and supposedly *a priori* cognitions of time and of other cognitions of like character in which the mathematical conception of time is presupposed¹. As in the case of space, Kant finds peculiar confirmation of his theory in the antinomy which results from taking the temporal order of events to be something independent of the subjective conditions of possible experience.

¹ Cf. Locke: 'a moment . . . is the time of one idea in our minds' (*Ess.*, loc. cit., § 9). Albertus Magnus (*Phys.*, iii. 3) cites Avicenna as objecting generally to the view of time as wholly mental, that it makes time consist of an aggregation of moments.

¹ Schopenhauer enumerates 28 *a priori* praedicabilia of time alone (*W. a. W.*, ii. 55 f.). Time, as such, is not the basis of any mathematical science, though Schopenhauer, and perhaps Kant, held it to be the foundation of arithmetic; but it is presupposed in the laws of motion and mathematical mechanics.

Kant, however, has made precise interpretation of his doctrine difficult, especially by his failure to distinguish clearly the psychological and the epistemological aspects of his inquiry and by the characteristic defect of his method in abstractly separating the process of perception from that of thought. Hence the oft-repeated criticism that the idea of time cannot be *a priori* because its development and special character are alike empirically conditioned; hence, too, on the other hand, the popular exposition which likens the 'intuition' of time to coloured glass as something independently given through which the perceptive soul sees its world. Relying, however, on Kant's own distinction between the *a priori* and the innate, we are justified in interpreting the real import of his doctrine at this point as strictly epistemological, as consistent with any theory of empirical conditioning that admits the originality of the function, as meaning, namely, that the idea of time precedes logically and in principle the perception of every particular time; and this seems to reflection true. Again, since the 'time-intuition' is only possible as a function, and time *in abstracto* is only definitely representable by ideal constructions in space¹, we may reject as inadequate and misleading the coloured-glass analogy, and interpret Kant here as really meaning that time is merely a form of perceptual experience, indeed, but that this form is a function in sense of that constructive synthesis he elsewhere attributes to thought. The essence of the Kantian doctrine will then be that temporal order is a product of the activity of the subject to which all experience is relative. The further definition of time in Fichte, Schelling, and Hegel depends on the way they severally interpret the subjective principle and the total constitution of the experience it determines. But even the realistic Herbart, while postulating an 'intelligible' space, regards time as a purely objective 'Schein,' the 'number of change' (*Met.*, §§ 287 ff.). The most precise elucidation, and perhaps the most original development of the subjectivistic doctrine of time since Kant, may probably be ascribed to Teichmüller (*Met.*, 192 ff.). Teichmüller conceives time as entirely a perspective order given to objects by a timeless, sub-

stantial ego, and duration as a mere immanent measuring of that order. According to this, if we abstract from the perspective nature of consciousness and the comparison, through memory and expectation, of part of its ideal content with other parts, all chronological arrangement and temporal duration disappear. The bare concept of time, he says, has in it nothing of magnitude, just as the concept 'mammal' has in it nothing of the specific nature of tiger, sheep, and elephant. Further, the determination of magnitude in the realm of time is purely relative. Hence the duration of the world has no absolute magnitude, nor has any given time-interval, a day or a second. The objective time-order is a perspective view, like every other. It is the product of scientific thinking, based on comparison of individual consciousnesses and aided by language. It is the order of history, and this order is true, but also, like every other content of scientific truth, timeless. A real order of actual activities corresponds to the perspective order, but this is to be ultimately conceived as a technical system. As all determination of duration is relative, we cannot say that the future is separated by any time-interval actually given from the present or the past. Indeed, taken absolutely, the whole series of the world's phenomena must be regarded as being all together at once. But only an absolute consciousness could so intuit it.

The standing objection to the doctrine thus or similarly expressed is that it denies the metaphysical reality of change. This objection is urged in various forms. It is said, for example, that if time is merely a form of intuition or a perspective ordering of phenomena, then the world is really a changeless unity, and consequently not only is all effort on our part to determine in any degree the course of things illusory, but past and future are contemporaneous—Nero is still burning Rome and the unborn babe now lives—which is absurd. Again, it is urged, positively, that change, and therefore time, which is the form of change, is real. For at least, it is argued, the succession of ideas is real, since it is only as ideas that phenomena can properly be said to exist at all. If, however, the succession of ideas is held to be phenomenal, the reply is that while this may be true if 'ideas' are taken as 'objects,' yet it is not true of the necessarily successive series of synthetic acts whereby their succession is presented. But not only, the argument continues, is

¹ 'Ohne Raum würde Zeit selbst nicht als Grösse vorgestellt werden' (*Lose Blätter*, i. 54). 'Die reine Anschauung bedeutet hier nicht etwas, was angeschaut wird, sondern die reine formale Bedingung, die vor der Erscheinung vorhergeht' (*Reflex.*, ii. 126).

change real in the subject, it is also real in external things; for the specific changes and the specific order of change appearing in objects, as they are certainly not due to a mere *a priori* form of the subject, imply a real succession in things themselves. Some writers appeal directly to the 'trans-subjective' nature of consciousness¹. Much of this criticism, however, loses its force when it is pointed out that the form of change, as such, is not time at all. Aristotle already distinguished between motion and time as number of motion. Time is a certain arrangement and measure of motion, a further determination of the content. It would be quite possible, therefore, to hold to any amount of real change and yet to regard the temporal view of such change as subjective. But the conception of a subject indifferently related to series of changes which it arranges in temporal order cannot, of course, be ultimate.

Time (cognition of). Of the various theories of the apprehension, cognition, or awareness of TIME (q. v.), the following types may be distinguished. Cf. *EXTENSION*.

(1) Intuitive and *a priori* theories, which

¹ Besides the references in *Vaihinger, Komm. z. Kant's Krit. d. reinen Vernunft*, ii. 403 ff., see especially Brömse, 'Die Realität der Zeit,' *Zeitsch. f. Philos. u. phil. Kr.*, cxiv. 27-63. Cf. also Lotze, *loc. cit.*; Ladd, *Theory of Reality*, 178 ff.

hold in some form that time, whether duration or succession, is a part of the individual's 'mental furniture': a time moment or temporal character is contributed by the mind to the structure of its experience as such. This is called nativism, and may be either (a) 'nativism of product,' illustrated by the theory of 'innate ideas,' and by that of '*a priori* mental forms.' See *TIME* (especially the view of Kant). Or it may be (b) 'nativism of process,' called also 'genetic nativism'—a class of views which hold that the awareness of time distinctions arises by some form of function or reaction of consciousness upon data of a certain character (see *TEMPORAL SIGN*). The function or way of acting is native to the mind, but it operates only on the stimulus of appropriate experiential conditions. Another view (c), which may also be classed as nativism, holds to an original temporal datum, a certain time-extent-attribute, or what we may call 'temporality,' attaching to experience as such. This is analogous to the 'extensity' theory of the cognition of *SPACE* (q. v.).

(2) Over against the nativism theories we find the 'empirical' theories. These—again under various forms—hold that time cognition is a gradual growth under the conditions of actual experiences of time. Bits of time are perceived, cognized, or experienced simply as such or as a property of events; and by abstraction and generalization time is built up as an independent mental object. The mind gets time out of its experience instead of contributing time to its experience.

The foregoing illustrates the older form of the discussion. The lines of opposition have been much blurred, however, by newer views of psychological function. These views treat the dualism of mind and its experience as largely a false dualism. Experience is a process, not a doctrine or series of data, and mind is also a process, and the two processes are not two but one. Hence all knowledge is in the same sense both native and empirical. This may be illustrated by the theory of temporality (and that of extensity in the matter of space cognition), classed above as nativism. It might just as well be classed as empiricism; for all the other attributes of experience which the empiricist recognizes (quality, intensity, &c. of sensation) are just as much 'native' as is this. Nothing but a mind could have any of them; but nothing but experience could beget any of them in a mind. The Kantian question—how is knowledge possible?—is put over again and an-

swered by denying the dualism of mind and its object. Knowledge or experience is the statement of the growth of a mind.

Psychologists generally hold the same type of theory for the two cases of space and time cognition, and the indications of individual views given under EXTENSION (q.v.) hold largely also for time.

Literature: see TIME; also the general works on psychology, and BIBLIOG. G, 2, v.

(J.M.B., G.F.S.)

Time Measurement: see MEASUREMENT, and REACTION TIME.

Time Perception: see TIME (cognition of).

Time Sense: Ger. *Zeitsinn*, *Zeitbewusstsein*; Fr. *sens du temps*; Ital. *senso del tempo*. A general term, analogous to 'space sense,' covering all conditions, attributes, and relations of temporal perception and idea; used more especially for investigations into the comparison of short time-intervals (durations). Cf., however, the remarks made under SENSATION AND SENSE (2).

The psychology of time is not yet so far advanced as to allow of the formulation of general laws. We know that the temporal sense discrimination is, under favourable circumstances, influenced or even determined by RHYTHM (q.v.). It seems that the apprehension of duration has at least three distinct forms (for intervals up to 1-2 sec., from 1-2 sec. to 3 sec., and from 3 sec. upwards), and that temporal ideas are peculiarly dependent upon the degree and direction of attention. Systematic investigation was begun by E. MEUMANN. See TEMPORAL SIGN, and cf. TIME.

ix. (1894) 264, xii. (1896) 127; F. SCHUMANN, Zeitsch. f. Psychol., iv. (1893) 1, xvii. (1898) 106, xviii. (1898) 1. (E.B.T.)

Timidity and **Timidity Reactions**: see SHYNESS.

Tissue (in physiology) [Lat. *texere*, to weave]: Ger. *Gewebe*; Fr. *tissu*; Ital. *tessuto*. Structure formed of similar elements, cells, or cell-products.

The principal tissues are: epithelial, connective, muscular, nervous, bony, cartilaginous, and vascular. (C.F.H.)

Tissue (social): see SOCIAL TISSUE.

Tone [Lat. *tonus*, a sound]: Ger. *Ton*; Fr. *son*, *ton*; Ital. (1, 2) *suono*, (3) *tono*. (1) The auditory sensation produced by a regular vibration of air particles. This, the true tone, is sometimes termed the 'simple' tone. See HEARING.

(2) The note of a musical instrument; a compound tone or 'simple clang.'

(3) A musical interval, the major second (larger or smaller; 8:9 or 9:10). Also called a 'whole tone.' Cf. SEMITONE.

(4) A general term, characterizing the number and consonance of overtones (e.g. 'rich' tone, 'pure' tone, 'harsh' tone, &c.). (E.B.T.)

The term 'chord' is in use for a number of compound tones sounded together; it serves that purpose sufficiently well, as against 'compound CLANG' (q.v.). (J.M.B.)

Tone (in compounds). See COLOUR TONE, FEELING, or AFFECTIVE HEDONIC TONE.

Tone-deafness: Ger. *Tontaubheit*; Fr. *surdité musicale*; Ital. *sordità musicale* (or *tonale*). A diminished capacity, or inability, to distinguish tones in general, or certain tones and their musical relations.

As a deficiency in musical discrimination in perfectly normal individuals, it is probably not uncommon; such persons fail to appreciate musical effects, and may not be able to distinguish between tones as much as an octave apart (see Grant Allen, *Mind*, April, 1878). An unusual deficiency in the capacity to hear very high or very low tones is spoken of as a partial tone-deafness.

Tone-deafness as a symptom in cerebral defect akin to aphasia relates to the specific loss or partial failure, on the sensory or receptive side, of the general musical faculty. It is thus related to AMUSIA (q.v.), as word-deafness to sensory aphasia. It is not an auditory defect, for tones are heard as noises; but the capacity to discriminate pitches and musical relations is impaired. See also

DEAFNESS (mental). For literature see AMUSIA. (J.J.)

Tone Tint: Ger. *Tonfarbe*; Fr. not in use (L.M.); Ital. not in use. An attribute of simple tones consisting in part of 'volume,' in part of intensity, and in part of pitch or quality (which forms the basis of tone tint in Stumpf's theory). See Stumpf, *Tonpsychologie*, ii. 540. (E.B.T.)

Tonic: Ger. *Tonica*; Fr. *tonique*; Ital. *tonica*. 'Modern music effects a purely musical internal connection among all the tones of a composition by making their relationship to one tone as perceptible as possible to the ear' (Helmholtz). This 'one tone' is the tonic or keynote. See Helmholtz, *Sensations of Tone*, 240; Wundt, *Physiol. Psychol.* (4th ed.), ii. 80. (E.B.T.)

Tonic (in physiology): Ger. *tonisch*; Fr. *tonique*; Ital. *tonico*. (1) Relating to the condition of relative responsiveness of the nervous system; tone being a condition in which muscular (and mental) efforts can be continued without undue fatigue, and with energy and a feeling of pleasure. Lack of tone (atony) is the relative absence of such a condition.

Tone is also used to indicate the general functional status of the neuro-muscular apparatus. For a normal healthy tone are required the presence of nervous energy (i.e. a rested condition), proper nourishment and oxygen, a removal of waste products, and not too excessive work. Pathological deficiency in these respects is an important factor in NEURASTHENIA (q. v.).

(2) Various tonics are therapeutic agents which impart more or less permanent strength to the body or some of its organs. In this sense, nux vomica, strychnine, arsenic, iron are administered as tonics to the nervous system. It is customary also to speak of mental and moral tonics.

(3) Tonic, as opposed to clonic, is applied to spasms, in which the muscles remain in a state of continuous, rather than intermittent, contractions. Cramps and contractures are tonic spasms. See SPASM, and cf. EPILEPSY. (J.J.)

Tort [Lat. *tortus*, twisted, wrenched]: Ger. *Unrecht*, *Rechtsverletzung*; Fr. *tort*, *délit* (*Code Civil*, Liv. II, tit. 5, chap. ii); Ital. *torto*. A wrongful act, other than a violation of contract, injuring another and entitling him to a civil action.

If the act causes no damage, it is not actionable, and so not a legal tort; but nominal damages are sufficient, and these the law may

imply in some cases. *Tort-feasor*: he who commits a tort. *Executor de son tort*: one who wrongfully acts as if he were an executor, and who can therefore be held to some of the obligations of an executor. The act which is a tort may also be a crime. In so far as it violates the rights of individuals considered as individuals, it is a tort; in so far as it violates the rights of the state (if at all), it is a crime. In English and American law the civil and criminal remedies must be pursued separately, for to sustain the latter more convincing evidence is necessary. In France they can be joined (*Code d'Instruction Criminelle*, Liv. I. chap. vi. 63; see *Dig.*, xlvii. 1, *de privatis Delictis*, 2).

'Generaliter iniuria dicitur omne quod non iure fit' (*Inst. of Just.*, iv. 4, *de iniuriis*, 1).

Literature: HOLMES, on the Common Law, chaps. iii, iv; MARKBY, *Elements of Law*, chap. xvi; SMITH, *Right and Law*, chap. viii; POLLOCK, *Torts*; *Two Centuries' Growth of American Law*, chap. v. (S.E.B.)

Totality: see WHOLE, and cf. UNITY AND PLURALITY.

Totem (-ism) [a North American Indian word]: Ger. *Totem*, *Totemismus*; Fr. *totem*, *totémisme*; Ital. *totem*, *totemismo*. A class of material objects (animals, plants, &c.) which the members of a community regard with superstitious respect, to which they hold themselves to be peculiarly and intimately related, and which becomes as well the social bond of union between fellow clansmen. The term was introduced by J. Long, 1791.

The totem is both religious and social. Its origin cannot be traced, but its extreme diffusion, both geographical and historical, entitles it to be regarded as a highly important factor in primitive mental life. It may be psychologically related to fetichism, but differs from the latter not only in its social significance, but also in that the influence attached to the totem covers all objects of a certain class, while the fetichistic powers reside in a special individual object only. The religious aspect of the totem is apt to involve the belief, or the myth, that the clan was by some mystery or miracle descended from the totemic animal or object; such animal or object thus becomes sacred, is tabooed as food, or for use in dress, and the proscription may extend even to the mention or sight of the object. The totem is looked to for protection from evil and the cure of disease. It is worshipped and respected, and a corresponding benefit is expected

from the totemic influence, while violations of its sacredness are severely punished. It enters into the ceremonies which attend birth, marriage, and death, and the assumption of the totem may characterize the rites of puberty.

Besides the clan totems there are also, but far less frequently, totems for men and women separately, and individual or private totems. The last may be selected by divination at the time of birth, or by dreaming of it at puberty, or in any other way which would naturally bring about a mysterious and hallowed connection.

On the social side the totem gives rise to a more or less elaborate system of clan and family relationships which may properly be spoken of as totemism. Indeed, the totemic is frequently a stronger tie than the family connection, and becomes a mark of cognizance for each member of the clan. The custom of exogamy or marriage outside the clan or totem requires a sharp recognition of the totem, and brings about a double totem, that of father and mother. According to the rule of descent, whether by father or mother (the latter more usually), the paternal or maternal totem passes to the child, thus ever widening and complicating the clan relations and regulations. The further recognition of special tribes as suitable companions for marriage, and the presence of sub-totems in special branches, may develop a most elaborate and complicated system of relationships. The totem becomes an important symbol of kinship, and is thus used in architecture (totem poles), in dress, and in decoration. (J.J.)

Literature: FRAZER, Totemism (1887); and Encyc. Brit. (9th ed.), art. Totemism (with references); MORGAN, Anct. Society (1878); TYLOR, Early Hist. of Mankind (1870); PIKLER and SOMLÓ, Der Ursprung d. Totemismus (1900); various authors in Reports of the Bureau of Ethnology (Washington). (J.M.B.)

Touch (physiology of): see SKIN.

Touch Sensation [ME. *touchen*]: Ger. *Tastempfindung*; Fr. *sensation tactile* (or *de tact*); Ital. *sensazione tattile, senso del tatto*. (1) Sometimes made synonymous with CONTACT SENSATION (q. v.), thus including CUTANEOUS SENSATION (q. v.), and also PRESSURE SENSATION (q. v.).

This usage is seen in the term active touch, the exploration of a surface by a portion of the skin.

(2) More properly restricted to cutaneous

sensation proper. This is the usage of those who distinguish between cutaneous sensation and pressure sensation (e.g. Dessoir). Cf. HAPTICS. (J.M.B.)

Trace or **Residuum** [Lat. *trahere*, to draw, through Fr., and Lat. *re- + sedere*, to sit]: Ger. *Spur, Rest*; Fr., *trace, résidu*; Ital. *traccia, residuo*. The supposed deposit or effect left by a nervous or mental function whereby later performances of the function are facilitated. Cf. FACILITATION.

The terms carry a structural connotation, an actual marking or path-making being supposed in the brain. The theory of the DISPOSITION (q. v.) is coming to give a more functional interpretation to the facts, and that term is displacing these. (J.M.B.—G.F.S.)

Tractarianism: Ger. *die Ansichten der Tractarianer*; Fr. *Tractarianisme*; Ital. *Tractarianismo*. A system of High Churchism, originating in the work of the Tractarians (so called from the papers 'Tracts for the Times'), a body of Oxford divines of the Church of England, who united doctrinal assertion of the historic organism and creeds of the Church, the saving efficacy of sacraments, baptismal regeneration, real presence in the Eucharist, and the power of the keys, with the practice of a more aesthetic ritual and a severer ideal of asceticism for the clergy. It is also called 'the Oxford Movement.'

The Oxford movement, originating in the early part of the 19th century as a reaction against the rationalistic and secularistic tendencies of the Church, with such leaders as Keble, Newman, and Pusey, promised a comprehensive reform. Soon, however, disintegrating tendencies began to prevail, and the forces were drafted off on one side in the direction of liberalism; on the other, into a reaction towards the Catholic Church. The movement gradually lost many of its purest spirits, and Tractarianism became a synonym for Puseyism, with its retrospective keenness and prospective blindness of vision. The principal fruitage of the movement has been a development of ritual and a revival of clerical asceticism.

Literature: NEWMAN, *Apologia pro Vita sua* (1864-8), and *Letters and Corresp.* (1890); COLERIDGE, *Memoir of the Rev. John Keble* (1869); CHURCH, *The Oxford Movement* (1891); WILFRED WARD, *W. J. Ward and the Catholic Revival* (1893). (A.T.O.)

Traction Sensation: see PULL SENSATION.

Tracy, Antoine Louis Claude Destutt,

Comte de (called **Destutt de Tracy**). (1754–1836.) Educated for the army, he was a member of the States-General in France, 1789. Of the revolutionary party, he served under Lafayette, was arrested, and released only after the death of Robespierre. Senator under the empire, he voted to depose Napoleon and against the reactionary restoration measures. He was a commander of the Legion of Honour, and member of the Academy. He was a prominent personage among the French Ideologists. Cf. IDEOLOGY, and SENSATIONALISM.

Trade [AS. *trod*, footstep, track]: Ger. *Handel*; Fr. *commerce*; Ital. *commercio*. The business of exchanging goods, as distinct from producing them. Cf. INDUSTRY.

It is not always possible to draw a sharp line of distinction between trade and industry, because there is no such line between processes of production and exchange. In fact, production can hardly be said to be complete until the goods are in the right hands. The distinction of principle is apparently this: the gains of industry are those due to skilful application of *physical* processes; the gains of trade are those due to clear perception of *social* wants. (A.T.H.)

Trade Union: Ger. *Gewerkverein*; Fr. *syndicat d'ouvriers*; Ital. *società* (or *lega operaia*). An association of labourers, engaged in the same business, for mutual assistance.

This assistance may take either of two main forms: mutual insurance, or the substitution of collective bargaining for competition. The latter is the more important, though by no means the more universal object.

A trade union has much greater power than an individual in dealing with a labour dispute, because it can enforce its demands by a strike. The greatness of this power creates a danger of unwise use—not so much in increasing the frequency of strikes as in trying to impose restrictions on the labour supply, which are disadvantageous to the public. The fear of these results caused the legislation and judicial decisions of the early part of the present century to be adverse to trade unions; but it is now generally believed that such legislation serves to accentuate the very evils it was intended to prevent. In fact, trade unions to-day are often more powerful in the legislature than out of it; and a 'new unionism' is growing up, especially in England, which relies on social and political means of advancing the cause of labour far more than on strictly industrial ones.

The mediaeval guilds were in a sense trade

unions; but their conditions were so different from those of labour organizations at the present day that their inclusion under the same term is really misleading. The Knights of Labour, and other organizations of labourers arranged with little reference to community of craft, are not, properly speaking, trade unions at all. (A.T.H.)

Tradition [Lat. *traditio*, delivery]: Ger. *Ueberlieferung*, *Tradition*; Fr. *tradition*; Ital. *tradizione*. The verbal or other social form of handing down of historical material, as opposed to its preservation in written records. Cf. HISTORY, the following topics, and TRANSMISSION. (J.M.B.)

Tradition (in biology and sociology). The handing down of knowledge, behaviour, modes of life, &c., from generation to generation without physical heredity; applied also to that which is thus handed down. Tradition involves individual acquisition.

Birds have a singing tradition, dogs a barking tradition, &c., as is proved by the fact that the young brought up in isolation do not perform these functions perfectly or 'true to kind.' The process of acquisition by the young, with their subsequent possession of what is transmitted, has been called social HEREDITY (q. v., 2).

The facts of tradition have important bearings upon theories of INSTINCT (q. v.), EVOLUTION (q. v.; cf. ORGANIC SELECTION), COMPARATIVE PSYCHOLOGY (q. v.), and SOCIAL ORGANIZATION (q. v.). Cf. also ORTHOPLASY.

Literature: WALLACE, Darwinism; LLOYD MORGAN, Habit and Instinct; and Animal Behaviour; titles by ROMANES, GROOS, and BALDWIN cited under EVOLUTION (mental). See also (sociological) BARTH, Philos. d. Gesch. als Sociol., i. 113 f. (J.M.B., C.L.L.M.)

Tradition (in law): Ger. *Einhändigung*, *Übergabe*; Fr. *tradition*; Ital. *tradizione*. Delivery of possession.

Tradition is a source of title to property by the law of nature; 'nihil enim tam conveniens est naturali aequitati, quam voluntatem domini volentis rem suam in alium transferre, ratam haberi (*Dig.*, xli. 1, *de acquirendo Rerum Dominio*, 9, § 3).

Literature: SAVIGNY, Recht des Besitzes. (S.E.B.)

Tradition (in theology): Ger. *Tradition*; Fr. *tradition*; Ital. *tradizione*. A mass of writings, which have been obtained either through alleged oral revelation or from uninspired writers, and which, together with the

written Scriptures, are accepted as authoritative in matters of doctrine and practice.

The principal bodies of tradition, in the theological sense, are the Jewish traditions, which are embodied in the Talmud, and the traditions of the Roman Catholic Church, which are composed of writings of the Non-Apostolic Fathers. The recognition of tradition as a source of doctrinal and practical principles is one of the features of Catholicism which led to the Reformation movement.

(A.T.O.)

Traducianism (in theology) [Lat. *traducere*, to train, propagate]: Ger. *Traducianismus*; Fr. *traducianisme*; Ital. *traducianismo*. The doctrine, opposed to CREATIONISM (q. v.), which teaches that the soul as well as the body is propagated in generation, and that God's work of creation ended on the sixth day in the creation of man, which was a racial and not an individual act.

Literature: SHEDD, Hist. of Christ. Doctrine, ii. 13.

(A.T.O.)

Tragedy: see TRAGIC (3).

Tragic [Gr. *τράγος*, from *τραγῳδία*, tragedy, lit. goat-song, perhaps from the goat-skin costumes worn by early tragic singers in imitation of satyrs]: Ger. *tragisch*; Fr. *tragique*; Ital. *tragico*. (1) Relating to tragedy (see below).

(2) Suited to tragedy, or having the characteristics of events portrayed in tragedy. This in looser usage is nearly equivalent to terrible or calamitous.

(3) More definitely in aesthetics: that quality of experience whereby, in and through some serious collision followed by fatal catastrophe or inner ruin, something valuable in personality becomes manifest, either as sublime or admirable in the hero, or as triumph of an idea. The situation itself or its portrayal is termed tragedy.

The characteristic subjective effect is that of a complex of strongly painful and pleasurable elements existing simultaneously, both of which may be regarded as arising from sympathy—the painful elements from sympathy with the sufferer in evil, present or future (pity and fear); the pleasurable from sympathy with the noble or heroic character displayed, or with the triumph of some idea (as in the case of guilt overtaken by catastrophe). Cf. SUBLIME. In the case of the tragic in art, there is the additional element of the aesthetically pleasing form in which the action, character, or situation is presented. The tragic presupposes a greater magnitude

in its objects or events than is necessarily involved in the pathetic (see PATHOS), and usually a more active collision. Formally, it is a species of aesthetic CONTRAST (q. v.) or of disturbed HARMONY (q. v.).

Plato pointed out the mixed character of the feeling of the tragic. Aristotle noted the serious quality and the element of magnitude in tragedy, named pity and fear as the emotions excited, and stated the result of tragedy to be the effecting of a CATHARSIS (q. v.) of such passions. He suggested also that the tragic catastrophe results from some fault or error. This, as the theory of tragic guilt, has been developed in various aspects by the school of Schelling and Hegel, especially by Vischer. Hegel regards it as the triumph of the universal, the idea, and the destruction of the individual. 'Presumption' or overstepping of the due bounds of finiteness on the part of the individual has been emphasized as tragic motive by Vischer, Carriere, and Zeising. The inevitable and inherently necessary character of the collision or catastrophe in many cases enhances the tragic effect; this has been interpreted (1) optimistically, by Hegel, Vischer, Carriere, and Schiller, who in some way make the loss of the individual exhibit the triumph of the idea, or of the moral nature; (2) pessimistically, by Schopenhauer and Bahnsen (*Das Tragische als Weltgesetz*, 1877). Recent writers (Lipps, Volkelt) reject the theory of guilt or poetic justice as applicable to more than a portion of tragic situations. Köstlin and Hartmann emphasize the element of contrast; according to Hartmann the tragic contrast is one requiring a transcendent resolution.

Literature: LIPPS, *Der Streit ü. die Tragödie* (1891); HARTMANN, *Asthetik* (1886); BAUMGART, *Handb. d. Poetik* (1887); GÜNTHER, *Grundzüge d. tragischen Kunst* (1885); BEYER, *Deutsche Poetik* (2nd ed., 1887), ii; FREYTAG, *The Technique of the Drama* (Eng. trans.); KÖSTLIN, *Asthetik* (1869); SANTAYANA, *Sense of Beauty*; KLEIN, *Gesch. d. Dramas d. Griechen u. Römer*, i (1865); VOLKELT, *Die Aesth. des Tragischen* (1897); and *Zeitsch. f. Philos.*, cxii. 1 ff.; KÜLPE, *Preussische Jahrb.* (1899), xcvi. 264 ff. Cf. also Commentaries on Shakespeare by GERVINUS, ULRICI, and MOULTON. (J.H.T.)

Training: see EDUCATION, and INSTRUCTION.

Trance [Lat. *transitus*, passed over]: Ger. *Verzückung*, *Entzückung*; Fr. *extase*, *sommeil*, 'trance' (Th.F.); Ital. 'trance'. A general

term covering certain very varied conditions of modified consciousness with their physical accompaniments, e.g. HYSTERIA, HYPNOSIS, ECSTASY, MEDIUM(ship), &c. See these terms. (J.J.—J.M.B.)

Trances in general are frequently characterized by a marked insensibility to ordinary stimulation, and a relative unconsciousness or altered consciousness of outward occurrences. The thoughts of the entranced subject may be sharply concentrated upon a narrow and absorbing range of ideas, frequently of a religious character; and he is usually unresponsive to any attempt to intrude other and more normal mental occupations. By attitude and expression, and it may be by spoken utterances, the individual indicates his or her profound alteration of personality, and the existence of an abnormal condition. Ordinarily, the automatic functions go on with but moderate interruption; but in extreme cases respiration and circulation are affected, and food is taken sparingly, or must be artificially administered.

The term is used variously and often vaguely. Many of the historical cases of ECSTASY (q. v.) are described as trance. Lethargy is another term often used as a synonym of trance; and cases of suspended animation or of exceptionally protracted and deep sleep are also called trance. The hypnotic condition was by earlier writers sometimes described as a trance state, and spiritualistic mediums and others who throw themselves into an hypnotic or similar condition are termed trance mediums. The altered conditions often exhibiting persistent automatism due to alcoholic excess have been described as alcoholic trance. Likewise cases of altered personality, such as that of Ansel Bourne (cited by Binet, *Alterations of Personality*), in which an individual takes up a new life with new surroundings and is totally ignorant of his own past, may be described as life in a trance. It thus appears that trance states present great varieties, and may ensue as the result of somewhat different abnormalities in the nervous system. As the nature of the physiological alteration which induces trance is unknown, the state can be described only with reference to the psychological symptoms which it presents. Of these a limited or altered sensibility to the ordinary stimulation of the environment, or a marked mental automatism of action, or an exaggerated suggestibility, or a rapt concentration, or a deep and almost coma-like sleep and insensibility, may be the most striking

feature. Cf. the literature cited under the special terms referred to. (J.J.)

Transcendence (in theology) [Lat. *transcendere*, to cross a boundary]: Ger. *Transscendenz*; Fr. *transcendance*; Ital. *trascendenza*. The doctrine that God, in his proper being and essential nature, is prior to and above the world; or that he has reality in himself apart from his works.

Transcendence contrasts and correlates with IMMANENCE (q. v.). It may be asserted in such a sense as to isolate God from the world, in which case it excludes immanence. It was the character of DEISM (q. v.) that it associated with a one-sided notion of transcendence that of an external and wholly mechanical relation of the deity to the world. Extreme assertion of immanence results in pantheism or naturalism. Extreme assertion of transcendence leads to deism, or else thrusts God out of all conceivable relation to the world. (A.T.O.)

Transcendent (-al): Ger. *transcendent* (-al); Fr. *transcendant* (-al); Ital. *trascendente* (-ale). (1) In scholastic thought, transcendent and transcendental were equivalent, and were applied to terms or notions higher than the CATEGORIES (q. v.) of Aristotle, and comprehending the latter. (The conception of the secondary character of the categories is due to Neo-Platonism.) Such concepts are *ens*, *unum*, *verum*, *bonum*, and afterwards *res* and *aliquid*.

(2) Kant distinguishes between transcendent and transcendental (though he is not always true to his formal definition). *Transcendent* applies to whatever lies beyond the realm of experience and of knowledge; the transcendent use of concepts is the illegitimate extension of concepts, valid within experience, to what is beyond experience—as the use of the concept of causality with reference to God. This term accordingly has a bad sense. *Transcendental*, on the contrary, is used in a good sense. It is applied to the *a priori* and necessary factors in experience; it accordingly does not go beyond experience, but beyond the empirically given factors of experience.

(3) Transcendent is opposed to immanent. See TRANSCENDENCE (in theology). (This is a connecting link with sense (2). Kant opposes the immanent use of his transcendental principles, remaining within the limits of experience, to the transcendent which goes beyond.) It is particularly used in religious philosophy as defining the relation of God to the world; the transcendent theory (first clearly formulated by Aristotle) holding

to the existence of God external to the universe, the immanent theory holding to the presence of God in the world (cf. PANTHEISM). See Eucken, *Fundamental Concepts*, 92-4; Vaihinger, *Commentar zu Kant*, i. 83-4, 467-76.

According to Prantl (*Gesch. d. Logik*, iii. 245), we owe to a pseudo-Thomas the term *transcendentia* to express the four highest concepts, and also the addition of the two new ones (*res* and *aliquid*), probably under Arabian influence. According to Prantl still further, St. Thomas Aquinas was influenced by the mystic *De Causis*, of Arabian origin, which attempted a Neo-Platonic derivation of the universals. St. Thomas avoided its pantheistic character, however, by giving them a theological cast—*ens* belongs to essence as such, *unum* to the Father, *verum* to the Son, and *bonum* to the Holy Spirit (*Gesch. d. Logik*, iii. 8-9, 114). Before this time the phrase 'transcendental terms' was used of the letters in the syllogistic figures, as signifying 'nothing and everything,' and as being 'without matter.' (J.D.)

Transcendental Realism: see REALISM (2).

Transcendentalism: Ger. *Transscendentalismus*; Fr. *transcendantalisme*; Ital. *transcendentalismo*. (1) The philosophy of the TRANSCENDENTAL (q.v., 2) in the Kantian sense. An explanation of the possibility of an *a priori* knowledge of objects, together with a systematic inventory of the concepts which may thus be applied, and of the principles which result from their application under proper conditions.

(2) Kant's successors attempted (through the elimination or transformation of the Kantian thing-in-itself) to unify the ultimate subject and object of knowledge, and thereby to give complete and not merely phenomenal value to the concepts of absolute or pure thought. This did away with the Kantian distinction of transcendent and transcendental; and transcendentalism comes to mean any theory asserting the dependence of the world upon the activity of reason, provided a systematic attempt is made (as in Fichte's *Wissenschaftslehre* and Hegel's *Logik*) to give a methodic development of reason into the particular categories that constitute the world of experience.

(3) In a loose sense, any philosophy which emphasizes the intuitive, spiritual, and supersensuous; any mode of thought which is aggressively non-empirical or anti-empirical.

Thus we hear of the transcendentalism of Emerson, &c. (J.D.)

Transcendentalism (in theology). The doctrine that the source of religious truth is an organ or process of super-ordinary apprehension called variously religious consciousness, mystical insight, or intuition, through which the truth is immediately realized. It is a form of religious MYSTICISM (q.v.).

The typical form of this organ is the intellectual intuition of Schelling, which gives truth, to use a Hegelian phrase, as it were, shot out of a pistol. Historically, the name is used to characterize the religious movement which arose in New England under the leadership of Bronson Alcott, Emerson, and others as a reaction against dogmatic rationalism, and was influenced by both Platonism and German idealism.

Literature: FROTHINGHAM, Transcendentalism in New England; the literature of MYSTICISM. (A.T.O.)

Transeunt: see IMMANENT AND TRANSEUNT ACTIVITY.

Transfigured Realism: see REALISM (2).

Transformation: see MATHEMATICS.

Transformation (in biology) [Lat. *trans* + *forma*, shape]: see TRANSFORMISM.

Transformation (in logic): Ger. and Fr. the same; Ital. *trasformazione*. The change of any statement into an equivalent statement in a different logical form. Such changes as occur in *a is always b = every a is b = a implies b = a is surely followed-by b* are changes of expression only, and not of logical form.

Wundt includes under the term transformation immediate inferences in which the new proposition states less than the one from which it is derived, but it is better to call such by a different name, as UNDER-STATEMENT (q.v.). Transformation of propositions is of two sorts: (1) transposition, in which some element of the subject or predicate is changed from one side to the other of the copula, as *Barking dogs do not bite = Dogs which bite do not bark*; *Not all a is non-b = Not all b is non-a*; or (2) a change in the character of the copula, as *A is the father of B = B is the son or daughter of A*; *None but fools cannot see this = All are capable of seeing this or are fools*; *No a is b = All a is not-b*. See PROPOSITION. Equipollent is the scholastic name for propositions which are logically equivalent.

Obversion is the transformation of a proposition into an equivalent proposition, (1) in which the subject remains the same and

the predicate becomes the contradictory of the original predicate, and (2) in which the copula is changed from positive to negative or the reverse, and also from symmetrical to unsymmetrical or the reverse. (C.L.F.)

Transformation (of energy): see CONSERVATION OF ENERGY, and ENERGY.

Transformism (or theory of **Transformation**) [Lat. *trans* + *forma*, shape]: Ger. *Transformationstheorie*; Fr. *théorie de la transformation, transformisme*; Ital. *teoria del trasformismo*. The theory of biological DESCENT (q. v.), viewed as involving the transformation of earlier into later forms. Cf. EVOLUTION, and NATURAL SELECTION (also for literature). (J.M.B.)

Transgression [Lat. *transgressio*, from *transgredi*, to pass over]: Ger. *Verbrechen*; Fr. *transgression*; Ital. *trasgressione*. In theology, transgression is identical with active sin, and consists in violating, disregarding, or ignoring the authoritative divine law as expressed in conscience or the written word. See SIN (also for literature). (A.T.O.)

Transient [Lat. *trans* + *ire*, to go]: Ger. *transgredient*; Fr. (2) *transitif*; Ital. (2) *transeunte*. (1) Transient, in its earlier use, is the equivalent of the post-Kantian term TRANSCENDENT (q. v.), as opposed to immanent.

(2) As applied to activity or causes, see reference under TRANSEUNT.

Aristotle distinguished *πράττειν* (doing) from *ποιεῖν* (making), the former denoting an activity expended upon itself, the latter upon bringing into effect some modification of an external existence. Conduct fell into the former sphere, art into the latter. The scholastics regularly distinguished between *causa* or *actio transiens* and *causa* or *actio immanens*. Thus St. Thomas Aquinas says *actio* is twofold; *transiens*, which goes forth into external material (to heat, to dry), and that which remains in the agent, as thinking, feeling, willing. See Eucken, *Grundbegriffe der Gegenwart*, 292 and note. (J.D.)

Transilient (variation and evolution): see NATURAL SELECTION, *passim*, and cf. MUTATION, and VARIATION (in biology).

Translation [Lat. *trans* + *latum*, part. of *ferre*, to bear, carry]: Ger. *Uebersetzung*; Fr. *traduction (transposition)*; Ital. *traduzione*. (1) In the literal sense, the rendering of one language into another.

(2) The statement of one subject in terms of another; the transference of a given line of argument from one sphere to another; the use of one set of facts to describe another

set, e.g. an essay in physics or physiology may be experimentally 'translated' into aesthetics or ethics, a statement of biological into a statement of economic fact.

"Mrs. Carnac" is the subject of one of the best and most highly prized of the mezzotints made under Sir Joshua's eye; it is interesting to learn that the pendant of this picture, Gainsborough's miraculous "Mrs. Robinson," has just been translated in the same medium by one of the most accomplished of the modern revivers of the art, Mr. Gerald Robinson, president of the Society of Mezzotint Engravers' (*The Times*, London, June 23, 1900). 'Lord Rosebery, as we have said, displays in a marked degree what may be called a theoretical knowledge of Imperial conditions. If he feels within himself the capacity and the energy to translate the knowledge into a practical programme, the way is plain before him' (*Times*, London, Nov. 19, 1900). Cf. SIGNIFICS. (V.W.)

Transmigration of Souls: see METEMPSYCHOSIS.

Transmission [Lat. *trans* + *mittere*, to send]: Ger. (1) *Ueberlieferung*, (2) *Fortpflanzung*; Fr. *transmission*; Ital. *trasmissione* (see also the equivalents for HEREDITY). (1) Social: the handing down from one generation to another of the material of TRADITION (q. v., in biology and sociology).

(2) Biological: (a) physical HEREDITY (q. v.), i.e. the inheritance of specific, or definite, characters; (b) the passage from parent to child by physical reproduction of the effects, not themselves specific or definite, of those conditions of life which modify the germ-cells of one or both parents, e.g. the effects of alcoholic poisoning upon subsequent generations.

For the distinction between (a) and (b) under definition (2), see HEREDITY. It is highly important in connection with the theory of Lamarckian inheritance. Only the form of transmission (a) is true heredity. In contrast with the transmission of general effects it has been called 'definite' transmission (see Ewart, Pres. Address, *Nature*, Sept. 12, 1901). The other case (b)—the appearance in the offspring of effects due to the influence of the parents' conditions of life—may well be called 'indefinite' transmission. The former is the transmission of characters, the latter the transmission of conditions or effects.

The phenomena of social transmission have long been recognized in the historical sciences. The attempt in recent years to found socio-

logy upon biology has raised the question of the relation of the facts of transmission in the two provinces respectively to each other. It is now seen, however, that the transmission of social material is by psychological processes, such as IMITATION (q. v.), &c., and that this differs essentially from that of biological heredity (cf. GALTON'S LAW, of ancestral inheritance, and REGRESSION).

Literature: WEISMANN, *Germ-Plasm*, and *Studies in Heredity*; recent expositions of EVOLUTION (q. v.). The literature of ORGANIC SELECTION, e.g., LL. MORGAN, *Habit and Instinct*; BALDWIN, *Development and Evolution* (1902); in both of which the relation of the two forms of transmission to each other is discussed. (J.M.B., E.B.P., C.L.L.M.)

Transmission (in neurology): see CONDUCTION under NERVE STIMULATION AND CONDUCTION.

Transmission (in theology and philology). Handing down by oral TRADITION (q. v.) as contrasted with written records. (J.M.B.)

Transposition (in logic) [Lat. *trans + ponere*, to place]: Ger. *Hinüberschaffen*; Fr. *transposition*; Ital. *trasposizione*. Transposition consists in transferring a term from the subject to the predicate, or the reverse, with no change in the character of the connection; as, *No artists who are bankers are clever, No artists are clever bankers, No bankers are clever artists, None are at once artists and bankers and clever*; or as *All but a is b, All but b is a*. Any proposition may be 'transformed' into other exactly equivalent forms: e.g. the transformation may consist in the change from one sort of connection to another (change of copula, in the extended meaning of that term), as—to take a compound proposition as an example—*It never rains but it pours = always either it pours or it does not rain*, but this is not transposition.

Certain copulas permit transposition simply, with no variation in the quality of the term transposed (as in the instances just given); but with the non-symmetrical copulas (see PROPOSITION) there must be a change from positive to negative or the reverse (and, if the proposition is complex, from the conjunctive to the alternative combination and the reverse), if the change can be made at all: He who is an astronomer and un-devout is mad = Any astronomer is mad or devout = All are mad or devout or not astronomers. When both the whole subject and the whole predicate is transposed the change is commonly called contraposition if the copula is non-

symmetrical (*All a is b = All non-b is non-a; None but a is b = None but non-b is non-a*), but simple conversion if it is symmetrical (*No a is b = No b is a, Some a is b = Some b is a*). The usual discussion in the logics of the doctrine of the equivalence of propositions is greatly simplified by taking this more general view of the subject (see PROPOSITION).

(C.L.F., C.S.P.)

Trans-subjective (the): Ger. (*das*) *Trans-subjektive* (Volkelt); Fr. (*le*) *transsubjectif*; Ital. (*il*) *transsubbiettivo*. The objective considered as having reality independent of its apprehension by a subject.

It is used, however, in connection with knowledge, which is said to have a trans-subjective reference, or to demand a 'realm of the trans-subjective.' As used by Volkelt (*Erfahrung u. Denken*, 42), all is trans-subjective 'was ausserhalb meines eigenen Bewusstseins Vorgänge geben mag' (quoted by Eisler). (J.M.B.)

Transubstantiation [Lat. *transubstantiatio*, from *transubstantiare*, to change into another]: Ger. *Transubstantiation*; Fr. *transubstantiation*; Ital. *transustanziazione*. In Catholic theology, the change of the elements in the Sacrament of the Eucharist, through the act of consecration, into the real body and blood of Christ.

It is to be distinguished from consubstantiation, the doctrine of the coexistence of Christ's body and blood with the elements which remain unchanged; from the doctrine of impanation or subpanation, that the body and blood are in or under the elements; also from all theories of the spiritual presence merely, i. e. as not involving the actual conversion of the elements. The doctrine, first broached by some of the Greek Fathers, was a question of debate during the middle ages, although held by the principal schoolmen. It was formally confirmed by the Lateran Council, 1225, the Council of Trent, 1551, and has since that time been the authoritative belief of the Roman Catholic Church.

Literature: WISEMAN, *Lects. on the Holy Eucharist*. (A.T.O.)

Traumatism [Gr. *τραῦμα*, a wound]: Ger. *Traumatismus*; Fr. *traumatisme*; Ital. *traumatismo*. A diseased condition produced by a wound, or by external violence. (C.F.H.)

Traumatrope: see ILLUSIONS OF MOTION AND MOVEMENT (1).

Treason: see HIGH TREASON.

Tree of Porphyry: Ger. *Baum des Por-*

TREE OF STRUCTURE — TRIBAL SELF

phyrinus; Fr. *arbre de Porphyre*; Ital. *scala ternaria di Porferio* (E.M.). The name given to the figure of a tree which appears in all the old logics.

It is supposed to illustrate the second chapter of the *Isagoge* of Porphyry, showing the genera on the trunk of the tree, and the specific differences on the branches, with substance at the top; cf. the figure for an outline.

It is also sometimes called and figured as a ladder, κλίμαξ, *scala praedicamentalis*, *Jacobs-leiter*, &c. (C.S.P.)

¹ 'Sortes' is the name universally employed in mediaeval logics as the example of an individual. It grew, no doubt, from an abbreviated spelling of Socrates. But it was pronounced as well as spelled Sortes, and had no connection, in the minds of those who disputed about logic, with the historical Socrates. Indeed, for generations, during the time in which it was in use, only the very learned knew anything about Socrates. One gloss, attributed to the famous Scotus Erigena, in explaining a statement that Socrates was killed by hellebore, narrates, for the information of those less erudite, that Socrates and Hellebore were two Greek philosophers, who became so warm in a logical dispute that the former fell a victim to the fury of the latter.

Tree Structure: see DENDRITE.

Tremor [Lat. *tremor*, a shaking]: Ger. *Tremor*, *Zittern*; Fr. *tremblement*; Ital. *tremore*. A continuous spasm of limited range.

Tremor may be physiological, as in shivering and chattering from cold, or the trembling from fear, and hardly passes the bounds of the normal in the ordinary tremors accompanying old age. In tremor of mental origin there seems to be a loss of the controlling power of the motor centres; and many abnormal tremors regularly become more marked under excitement, embarrassment, fear, and other mental disturbances. Tremors are usually symptomatic of abnormal nervous conditions; and as such the precise variety and progress of the tremor become of considerable diagnostic value. Tremors are characteristic of the effects of poisons, such as alcohol, mercury, lead, opium, &c. (see ALCOHOLISM). In paralysis agitans (see PARALYSIS) the tremor is most significant, and its changes mark the stages of the disease; in CHOREA, in general PARALYSIS, in HYSTERIA, &c., tremors are also important diagnostic symptoms (cf. these terms, and also MOVEMENT, disorders of). (J.J.)

Trendelenburg, Friedrich Adolf. (1802-72.) Born at Eutin, he studied philology and philosophy at Kiel, Leipzig, and Berlin. Private tutor in the family of Postmaster-General von Nagler, 1826-33; professor extraordinary at Berlin, 1833; professor ordinary there, 1837; member (1846) of the Berlin Academy and secretary (1847-72) of the 'historico-philosophical' section. He was made Knight of the Order of Merit on the day of his death.

Trephine [Gr. *τρύπανον*, an auger, a borer]: Ger. *kleiner Schädelbohrer*; Fr. *tréphine*; Ital. *trapano*. (1) A cylindrical hand-saw, generally provided with removable centre-pin, for removing a circular disk or button from the skull.

(2) Verb: to open the skull with a trephine. (C.F.H.)

Triad [Gr. *τριάς*, the number three]: Ger. *Dreiklang*; Fr. *accord (de trois sons)*, *accord parfait* (c, e, g); Ital. *trio*. A chord of three tones, simple or compound.

The major triad c-e-g (major third + minor third) and the minor triad c-e♭-g (minor third + major third) are the bases of all other major and minor chords respectively.

Literature: HELMHOLTZ, *Sensations of Tone* (Eng. trans.), 212. (E.B.T.)

Tribal Self: Ger. *Stammes-(Volks-)seele*,

Gesamtpersönlichkeit (Wundt); Fr. *conscience sociale, moi tribal*; Ital. *Io tribole* (or *soziale*). The psychological factors involved in the organization of a social group (tribe), when conceived, after analogy with the individual's mental organization, in the form of a personal self.

The conception is often vague, and stands upon much the same plane as that of GENERAL (or Social) WILL (q. v.). (J.M.B., F.H.G.)

Tribē [Lat. *tribus*, a third part]: Ger. *Stamm*; Fr. *tribu*; Ital. *tribù*. (1) One of the three divisions of the Roman people recognized at the beginning of their recorded history.

(2) An organized group or band of persons, usually compound, the component groups being allied hordes or related clans, and all speaking a common language or dialect.

A tribe is essentially a military organization, and usually has a military council and a chief. It should not be confounded with a CLAN (q. v.), which is essentially a juridical organization.

The word *tribe* has equivalents in all languages except those of the lowest hordes, and tribes have been loosely described in all ancient and mediaeval literatures; but the scientific description and definition (2) were first made by Lewis H. Morgan, *The League of the Iroquois* (1849), *Systems of Consanguinity and Affinity* (1871), and *Ancient Society* (1877). (F.H.G.)

Tribunal (legal): see COURT.

Trichotomy (in theology) [Gr. *τρίχα*, in three, + *ταμεῖν*, to divide]: Ger. *Dreitheilung*; Fr. *trichotomie*; Ital. *tricotomia*. The threefold distinction of the nature of man into body (soma), soul (psyche), and spirit (pneuma).

This view has its germ in the New Testament, in such passages as 1 Thess. v. 23. It was advocated by Origen and opposed by Augustine and Tertullian, who held the dichotomic view. The distinction has survived to the present day, the trichotomic doctrine finding its principal exponents among German theologians, while its chief opponents are found among English divines.

Literature: DELITZSCH and PECK, *Bib. Psychol.*; J. B. HEARD, *The Tripartite Nature of Man* (1870); the literature of PSYCHOLOGY (biblical). (A.T.O.)

Trilemma [Gr. *τρεῖς*, three, + *λήμμα*, something taken]: Ger. *Trilemma*; Fr. *trilemme*; Ital. *trilemma*. A SYLLOGISM (q. v.) with three conditional propositions, the major pre-

mises of which are disjunctively affirmed in the minor (*Cent. Dict.*). Cf. DILEMMA. (C.S.P.)

Trinitarianism [Lat. *trinitas*, from *trinus*, threefold]: Ger. *Dreieinigkeitslehre*; Fr. *trinitarisme*; Ital. *trinitarianismo*. That doctrine of the divine nature which represents the Godhead as combining tripersonality with unity of individual substance and being.

The Trinitarian conception, which received its first authoritative statement in the Athanasian Creed, has its germ in the New Testament, which ascribes divine functions to Father, Son, and Spirit. The necessity arose of reconciling this plurality with the essential unity of the Godhead so as to avoid polytheism. The fierce controversy between Arians and Trinitarians ended in the triumph of the latter and the adoption of the Trinity as the central dogma of the Christian faith, a position which it has historically maintained.

Literature: LIDERER, *Christl. Dogmatik* (1849); BAUER, *Die christl. Lehre v. d. Dreieinigkeit*; SHEDD, *Defence of Nicene Creed*; HODGE, *Hist. of Christ. Doctrine*; O. OSTERZEE, *Christ. Dogmatics* (1841-3); DORNER, *Syst. of Christ. Belief*. (A.T.O.)

Trinity: Ger. *Dreieinigkeit*; Fr. *Trinité*; Ital. *Trinità*. The Deity as represented in Nicene theology, including three personalities, Father, Son, and Holy Spirit, in one essentially unitary substance. The doctrine is often called that of 'tripersonality.'

For discussion and literature see TRINITARIANISM, ARIANISM, and ATHANASIAN CREED. (A.T.O.)

Tripersonality: see TRINITY.

Tritheism (in theology) [Gr. *τρεῖς*, three, + *θεός*, God]: Ger. *Tritheismus*; Fr. *trithéisme*; Ital. *treteismo*. A conception of the TRINITY (q. v.), which virtually represented the Father, Son, and Spirit as three distinct individuals, predicated distinction of substance as well as of personal manifestation.

This view arose as a polytheistic reaction against extreme monotheistic tendencies. It originated in Alexandria in the 6th century, and was championed by Philoponeus, Conon of Tarsus, Eugenius of Seleucia, and others. Later the party appeared in Constantinople, where a disputation was held between its representatives and the Patriarch John. The tendency has practically disappeared from later Christian thought.

Literature: see TRINITARIANISM. (A.T.O.)

Triune God [Lat. *tres*, three, + *unus*, one: three in one]: Ger. *der dreieinige Gott*; Fr. *le Dieu en trois personnes*; Ital. *Dio uno*

e trino. An appellation of God employed in Trinitarian theology, used to express the tri-personality of the one divine substance. See TRINITARIANISM (also for literature). (A.T.O.)

Trivium [Lat. a cross-road, public square; in scholastic Latin the three arts of grammar, logic, rhetoric]. A term used throughout the scholastic period (for example, by Dante) for the three arts, grammar, logic, and rhetoric. Cf. PHILOSOPHY, *passim*. (C.S.P.)

Trophism [Gr. τροφή, nourishment]: Ger. *trophische Funktion*; Fr. *influence trophique*; Ital. *trofismo*. That power or control which the nervous system exercises over growth and metabolism in various parts of the body. The term trophic nerves was first used by Samuel.

Permanent changes are produced in the structure of the body by changes in or suppression of the nervous influence. Such are atrophy, aplasy, hypertrophy, hyperplasy, paraplasia, and various neuropathies. The classical experiment is the section of the ischiatic nerve, which not only produces paralysis of the leg, but is followed by swelling, inflammation, and spontaneous ulceration and decubitus. At the same time an irritable zone develops upon the neck, the mere touch of which is sufficient to bring on an attack of epilepsy (in rodents).

The effects of nervous weakness or excitement upon the hair and skin, and a long list of diseases of neurotic origin, illustrate the perversions of trophic action (erythema, erysipelas, urticaria, herpes, prurigo, eczema, pemphigus, pityriasis, acne, furunculi, &c.). Even embryonic development seems to be largely under nervous control, at least in later stages. The power of self-repair is lost upon the section of the nerve supplying a muscle.

Gaule reports that he has been able to produce within five or ten minutes a localized sore on the surface of the exposed biceps by electrically irritating the corresponding spinal ganglion. These and other facts discredit the idea of special trophic nerves, but accrue to the theory that all nerves are trophic in their action upon the part which they innervate. Cf. END-ORGAN.

Literature: ARNDT, Über trophische Nerven, Arch. f. Anat. u. Physiol. (1891); J. GAULE, Deutsch. med. Wochens., xx (1894); trans. of same, in Brain, xvii (1894); and Congrès Int. d. Sci. Méd., Arch. Ital. de Biol., xxii (1895); SCHIFF, Deutsch. med. Wochens. (1888); VIRCHOW, Handb. d. speciellen Pathol. u. Therapie (1854). (H.H.)

Tropism [Gr. τρένω, to turn]: Ger. *Tropismus*; Fr. *tropisme*; Ital. *tropismo*. The property possessed by certain organisms (plants), or their organs, of turning, in whole or part, towards a source of stimulation in the environment, as towards the sun (heliotropism), towards the earth (geotropism), &c.

It is often used in compounds. On certain of the tropisms and the terminology of the subject see Roux, Arch. f. Entwicklungsmech. d. Organismen, viii. 2 (1899), 355.

(J.M.B., E.B.P.)

Trust: see FAITH, and RELIGION (psychology of, 'dependence').

Trust (corporate) [ME. *trust* and *trist*]: Ger. *Verband*; Fr. *syndicat*, (3) '*trust*'; Ital. *sindacato*. (1) A device by which stockholders put their shares in the hands of trustees, to secure permanence of management.

(2) The practice of putting shares of companies which might compete into the hands of the same trustees, so as to secure harmony of action.

(3) Any device for the permanent restriction of competition. This is the current sense of the word to-day.

A trust differs from a pool chiefly in the element of permanence. A pool is a contract, and being in restraint of trade, has in America little or no legal sanction. It is therefore precarious. A trust agreement is in the nature of things permanent until the trust itself is dissolved. But the legislation against trusts has in recent years so far endangered their existence that it is difficult to find in America any means of permanently restraining competition, or even the abuses of competition, short of actual consolidation. (A.T.H.)

Truth and Falsity (1) and (2) **Error** [AS. *treowth*, Lat. *falsus*, false, and *error*, wandering]: Ger. (1) *Wahrheit und Falschheit*, (2) *Irrthum*; Fr. (1) *vérité et fausseté*, (2) *erreur*; Ital. (1) *verità e falsità*, (2) *errore*. 'Truth' and 'falsehood' are used in two main senses, according as (a) our belief in some proposition, (b) the proposition which we believe, is said to be true or false. True and false belief may be defined, respectively, as belief in propositions which are true or false: and *error* denotes false belief. Further, true and false propositions may be called, respectively, *truths* and *errors*. *Falsehood*, however, or *falsity*, and not *error*, is used to denote that property of a false proposition in virtue of possessing which it is called an error.

'True' and 'false,' as applied to proposi-

tions, denote properties attaching to propositions which are related to one another in such a way that every proposition must be either true or false, and that to every true proposition there corresponds a false one, and to every false proposition a true one, differing from it only as being its negation. There are, properly speaking, no degrees of truth or falsehood, but one error may be said to be truer or more erroneous than another, according as a greater or smaller number of the propositions it implies are true.

The following proposed definitions call for notice, both because of their wide acceptance, and because a notice of them will serve to isolate the properties which the terms really denote.

(1) It is commonly supposed that the truth of a proposition consists in some relation which it bears to reality; and falsehood in the absence of this relation. The relation in question is generally called a 'correspondence' or 'agreement,' and it seems to be generally conceived as one of partial similarity; but it is to be noted that only propositions can be said to be true in virtue of their partial similarity to something else, and hence that it is essential to the theory that a truth should differ in some specific way from the reality, in relation to which its truth is to consist, in every case except that in which the reality is itself a proposition. It is the impossibility of finding any such difference between a truth and the reality to which it is supposed to correspond which refutes the theory. For:—

(a) It is now generally agreed that the difference does not consist in the fact that the proposition is a mere grammatical sentence or collection of words; but that the popular sense, in which a *statement* may be said to be true or false, is merely derived from that in which what it signifies may be so.

(b) It is, however, generally held that the difference consists in the fact that the proposition is a *mental* copy of the reality, or an 'idea.' This view seems to be solely due to the almost universal error, whereby the *object* of a belief or idea is regarded as the attribute or content of such belief or idea; an error which is refuted by the fact that it denies the existence of that unique relation which we mean by knowing, and is therefore never consistently held: e.g. those who hold this view must, in consistency, deny any difference between those senses of truth in which it is

applied to a belief and to the object of such belief—a difference which in practice they cannot fail to recognize; for no one ever consistently held that when two persons are said to know the same truth, all that can be meant is that their states of mind are similar.

(c) No other difference has ever been proposed; and, indeed, once it is definitely recognized that the proposition is to denote, not a belief or form of words, but an *object* of belief, it seems plain that a truth differs in no respect from the reality to which it was supposed merely to correspond: e.g. the truth that I exist differs in no respect from the corresponding reality—my existence. So far, indeed, from truth being defined by reference to reality, reality can only be defined by reference to truth: for truth denotes exactly that property of the complex formed by two entities and their relation, in virtue of which, if the entity predicated be existence, we call the complex real—the property, namely, expressed by saying that the relation in question does truly or really hold between the entities. [Cf. the section *Psychological*, below, which states somewhat similar reasons for rejecting the 'correspondence' view. In the following, '*Logical*,' section, however, the 'correspondence' view is presented.—J.M.B.]

(2) It seems to be frequently implied that the truth of a proposition may consist in its relation to other propositions—in the fact that it 'fits into a system.' This view, however, simply neglects the admitted fact that any logical relations which hold between a set of true propositions will also hold between a set of false ones; i.e. that the only kind of system into which a true proposition will fit, and a false one will not, is a system of true propositions. The view derives its plausibility merely from the fact that the systems of propositions considered are ones to which we are so thoroughly accustomed that we are apt to regard their contradictories as not merely false but self-contradictory.

The Greek and Latin equivalents for 'true' and 'false' are respectively ἀληθής, *verus*; ψευδής, *falsus*. Error has the equivalents ἀμαρτία or ἀμαρτήμα, and *error*; but 'falsehood' as distinguished from 'error,' i.e. as denoting the property of a false proposition, has no corresponding abstract noun in Greek nor in classical Latin. There is, properly speaking, no history of the terms, since they have always been used in philosophy and always in very much the same senses. That truth consists

in some relation of words to what they signify, or even to one another, has indeed been seriously held at various times; and the fact that it seems scarcely necessary any longer to discuss that view, perhaps marks some progress in the conception of the terms. The view that truth consists in relation to a system owes its vogue to Kant's theory of experience, which appears to make the objectivity of a judgment consist in the fact that its subject is related to other subjects, and does not clearly distinguish objectivity from truth. It should, perhaps, be noted that error or false belief has been frequently held to consist, not in consciousness of something different from the truth, but merely in absence of consciousness of the truth or of the whole truth—a view which naturally follows as one of the alternative inferences from the premise that false = not-true, and from the premise that consciousness of the truth = true consciousness. (G.E.M.)

Logical. (1) Truth is a character which attaches to an abstract proposition, such as a person might utter. It essentially depends upon that proposition's not professing to be exactly true. But we hope that in the progress of science its error will indefinitely diminish, just as the error of 3.14159, the value given for π , will indefinitely diminish as the calculation is carried to more and more places of decimals. What we call π is an ideal limit to which no numerical expression can be perfectly true. If our hope is vain; if in respect to some question—say that of the freedom of the will—no matter how long the discussion goes on, no matter how scientific our methods may become, there never will be a time when we can fully satisfy ourselves either that the question has no meaning, or that one answer or the other explains the facts, then in regard to that question there certainly is no *truth*. But whether or not there would be perhaps any *reality* is a question for the metaphysician, not the logician. Even if the metaphysician decides that where there is no truth there is no reality, still the distinction between the character of truth and the character of reality is plain and definable. Truth is that concordance of an abstract statement with the ideal limit towards which endless investigation would tend to bring scientific belief, which concordance the abstract statement may possess by virtue of the confession of its inaccuracy and one-sidedness, and this confession is an essential ingredient of truth. A further explanation of what this

concordance consists in will be given below. Reality is that mode of being by virtue of which the real thing is as it is, irrespectively of what any mind or any definite collection of minds may represent it to be. The truth of the proposition that Caesar crossed the Rubicon consists in the fact that the further we push our archaeological and other studies, the more strongly will that conclusion force itself on our minds for ever—or would do so, if study were to go on for ever. An idealist metaphysician may hold that therein also lies the whole *reality* behind the proposition; for though men may for a time persuade themselves that Caesar did *not* cross the Rubicon, and may contrive to render this belief universal for any number of generations, yet ultimately research—if it be persisted in—must bring back the contrary belief. But in holding that doctrine, the idealist necessarily draws the distinction between truth and reality. [Cf., however, the section *Psychological*, below.—J.M.B.]

In the above we have considered positive scientific truth. But the same definitions equally hold in the normative sciences. If a moralist describes an ideal as the *summum bonum*, in the first place, the perfect truth of his statement requires that it should involve the confession that the perfect doctrine can neither be stated nor conceived. If, with that allowance, the future development of man's moral nature will only lead to a firmer satisfaction with the described ideal, the doctrine is true. A metaphysician may hold that the fact that the ideal thus forces itself upon the mind, so that minds in their development cannot fail to come to accept it, argues that the ideal is *real*: he may even hold that that fact (if it be one) constitutes a *reality*. But the two ideas, *truth* and *reality*, are distinguished here by the same characters given in the above definitions.

These characters equally apply to pure mathematics. Projective geometry is not pure mathematics, unless it be recognized that whatever is said of rays holds good of every family of curves of which there is one and one only through any two points, and any two of which have a point in common. But even then it is not pure mathematics until for points we put any complete determinations of any two-dimensional continuum. Nor will that be enough. A proposition is not a statement of perfectly pure mathematics until it is devoid of all definite meaning, and comes to this—that a property of a certain icon is

pointed out and is declared to belong to anything like it, of which instances are given. The perfect truth cannot be stated, except in the sense that it confesses its imperfection. The pure mathematician deals exclusively with hypotheses. Whether or not there is any corresponding real thing, he does not care. His hypotheses are creatures of his own imagination; but he discovers in them relations which surprise him sometimes. A metaphysician may hold that this very forcing upon the mathematician's acceptance of propositions for which he was not prepared, proves, or even constitutes, a mode of being independent of the mathematician's thought, and so a *reality*. But whether there is any reality or not, the truth of the pure mathematical proposition is constituted by the impossibility of ever finding a case in which it fails. This, however, is only possible if we confess the impossibility of precisely defining it.

The same definitions hold for the propositions of practical life. A man buys a bay horse, under a warranty that he is sound and free from vice. He brings him home and finds he is dyed, his real colour being undesirable. He complains of false representations; but the seller replies, 'I never pretended to state every fact about the horse; what I said was true, so far as it professed to be true.' In ordinary life all our statements, it is well understood, are, in the main, rough approximations to what we mean to convey. A tone or gesture is often the most definite part of what is said. Even with regard to perceptual facts, or the immediate judgments we make concerning our single percepts, the same distinction is plain. The percept is the reality. It is not in propositional form. But the most immediate judgment concerning it is abstract. It is therefore essentially unlike the reality, although it must be accepted as true to that reality. Its truth consists in the fact that it is impossible to correct it, and in the fact that it only professes to consider one aspect of the percept.

But even if it were impossible to distinguish between truth and reality, that would not in the least prevent our defining what it is that truth consists in. Truth and falsity are characters confined to propositions. A proposition is a sign which separately indicates its object. Thus, a portrait with the name of the original below it is a proposition. It asserts that if anybody looks at it, he can form a reasonably correct idea of how the original looked. A sign is only a sign *in*

actu by virtue of its receiving an interpretation, that is, by virtue of its determining another sign of the same object. This is as true of mental judgments as it is of external signs. To say that a proposition is true is to say that every interpretation of it is true. Two propositions are equivalent when either might have been an interpretant of the other. This equivalence, like others, is by an act of abstraction (in the sense in which forming an abstract noun is abstraction) conceived as identity. And we speak of believing in a proposition, having in mind an entire collection of equivalent propositions with their partial interpretants. Thus, two persons are said to have the same proposition in mind. The interpretant of a proposition is itself a proposition. Any necessary inference from a proposition is an interpretant of it. When we speak of truth and falsity, we refer to the possibility of the proposition being refuted; and this refutation (roughly speaking) takes place in but one way. Namely, an interpretant of the proposition would, if believed, produce the expectation of a certain description of percept on a certain occasion. The occasion arrives: the percept forced upon us is different. This constitutes the falsity of every proposition of which the disappointing prediction was the interpretant.

Thus, a false proposition is a proposition of which some interpretant represents that, on an occasion which it indicates, a percept will have a certain character, while the immediate perceptual judgment on that occasion is that the percept has not that character. A true proposition is a proposition belief in which would never lead to such disappointment so long as the proposition is not understood otherwise than it was intended.

All the above relates to *complex truth*, or the truth of propositions. This is divided into many varieties, among which may be mentioned *ethical truth*, or the conformity of an assertion to the speaker's or writer's belief, otherwise called *veracity*, and *logical truth*, that is, the concordance of a proposition with reality, in such way as is above defined.

(2) The word *truth* has also had great importance in philosophy in widely different senses, in which it is distinguished as *simple truth*, which is that truth which inheres in other subjects than propositions.

Plato in the *Cratylus* (385 B) maintains that words have truth; and some of the scholastics admitted that an *incomplex sign*, such as a picture, may have truth.

But *truth* is also used in senses in which it is not an affection of a sign, but of things as things. Such truth is called *transcendental truth*. The scholastic maxim was *Ens est unum, verum, bonum*. Among the senses in which transcendental truth was spoken of was that in which it was said that all science has for its object the investigation of *truth*, that is to say, of the real characters of things. It was, in other senses, regarded as a subject of metaphysics exclusively. It is sometimes defined so as to be indistinguishable from reality, or real existence. Another common definition is that truth is the conformity, or conformability, of things to reason. Another definition is that truth is the conformity of things to their essential principles.

(3) *Truth* is also used in logic in a sense in which it inheres only in subjects more complex than propositions. Such is *formal truth*, which belongs to an argumentation which conforms to logical laws. (C.S.P.)

Psychological. The psychological criticism of the notion of reality seems to be reducing it to that of truth, and in so far as to be making it difficult to put the 'correspondence' theory of truth in any tenable form. If in its essential, no less than in its genetic, meaning reality = is that which consciousness somewhere and somehow finds it possible to believe or accept as true, then it is a vicious circle to define truth as that which corresponds to or that which approximates to reality. The reality-coefficient, it seems safe to say, can be attached to this or that mental content only through the acceptance of the latter by consciousness for practical or other purposes; and when we come to ask for something which can be considered the irreducible character of truth, we find it to be, so far as the conscious recognition of it is concerned, also its acceptance for practical or other purposes. The fundamental difficulty with a 'correspondence theory' is this: it assumes a reality with which that which claims to be true may be compared, in order to find out whether it really be true or not. This is to say that we have a system of realities which have not been derived through the processes of selection in which alone just those tests arise which constitute them truths. Genetic analysis shows that by our active accommodations to whatever there is to accommodate to we select out bits of workable experience, hypostatize them under the name of reality, and thus, through gradual accretion to the store—both the individual and the racial store—we en-

large the range of truth with the reflection of it *pari passu* which constitutes reality. It would then be necessary to say, as the present writer (*Psychol. Rev.*, Jan., 1898, 1 ff.) has said in common with a German writer (Simmel, *Arch. f. syst. Philos.*, i. 34 ff.): 'truth is not selected because it is true (to reality): it is true because it has been selected.' And it might be said with equal justification: reality is not that to which truth must correspond; truth, on the contrary, is that to which reality must correspond.

The genetic reasons for the common-sense view—and also for the logical view (see above, *Logical*)—that goes by the term 'correspondence' appear to be plain. By the historical growth of tradition, authority, science, &c., and by the reflection of great standard formulations in the congenital equipment of individuals, a system of realities is recognized into which all are educated and to which all minor statements and beliefs are made to conform. This body of established truths has certain characters—permanency, consistency, compelling quality, &c.—which in our hypostatizing of reality come to be criteria of truth. According as new formulations, items, reported facts stand tests by these criteria, they are brought into correspondence with the reality of which such tests are functions; so that they are said to be, and they are able to remain, *true*. In so far, therefore, the correspondence view has grounds to rest upon, and in this sense it applies to a very wide series of cases. But it still remains that, if these considerations be true to psychology, for purposes of definition, truth is the ultimate and reality the derived term.

Literature: that of EPISTEMOLOGY, and LOGIC; BIBLOG. B, 1, d, and C, 2, g; citations under SELECTIVE THINKING. (J.M.B., C.L.F.)

Truth (in theology): Ger. *Wahrheit*; Fr. *vérité*; Ital. *verità* (*di Dio*, &c.—E.M.). Truth as a divine attribute is to be understood as the exact correspondence between the divine thought and reality; or the exact correspondence between the divine promise and its fulfilment. Cf. ATTRIBUTE (of God).

The former constitutes God's thought the ultimate ground and criterion of truth, while the latter constitutes his word the ultimate standard of faithfulness. (A.T.O.)

Tschirnhausen, Graf von, Walther Ehrenfried, Herr von Kisslingswalde und Stolzenberg. (1651–1708.) Studied at Leyden, chiefly mathematics. Volunteer in Holland, where he met Huyghens and became

familiar with Cartesianism. Became acquainted, later, with Spinoza. Journeyed to England, to Italy, to Vienna, and for a second time to France, where he became member of the Academy. After 1695 he lived at his castle, ground lenses, made chemical experiments, and died deeply regretted by Leibnitz.

Tucker, Abraham. (1705-74.) Born in London, and educated at Merton College, Oxford. He entered the Inner Temple, but retired to private life at Betchworth, where he died.

Twofold Truth (doctrine of the): see SCHOLASTICISM, II (1).

Tychism [Gr. *τύχη*, chance]: not in use in the other languages. A term introduced by C. S. Peirce to denote the theories which give to chance an objective existence in the universe, instead of regarding it as due to our lack of knowledge; a theory which gives both chance and necessity share in the process of evolution.

'The mere proposition that absolute chance . . . is operative in the cosmos may receive the name of Tychism.' Evolution by fortuitous variation he calls tychasm, and the theory that regards this as of principal importance tychasticism (*Monist*, iii. 188). The term appears to be first used (*ibid.* ii. 533) as follows: 'I endeavoured to show what ideas ought to form the warp of a system of philosophy, and particularly emphasized that of absolute chance. In the number for April, 1892, I argued further in favour of that way of thinking, which it will be convenient to christen *tychism* (from *τύχη*, chance).' (J.D.)

Type (in biology) [Gr. *τύπος*, a print, impression]: Ger. *Typus*; Fr. *type*; Ital. *tipo*. (1) The central form about which the VARIATIONS (q. v.) centre.

(2) In systematic botany and zoology: the individual specimen upon which the first description of a species is based.

The modern idea of type is essentially statistical. It was first established by Quetelet (*Anthropométrie*) and has been greatly developed by Francis Galton. For a discussion of the statistical type as applied to species see C. B. Davenport, in *Science*, vii. 685, and xiv. 315; also *Statistical Methods* (1900). (C.S.M.)

The older philosophical conception of type, which meaning (1) above puts into mathematical form, is that of a perfect or universal example or *idée*, to which particular instances more or less fully approximate. This existed either as a pattern in the creator's mind or as an immanent teleological principle. Agassiz,

among naturalists, made the type a 'divine thought.' Cf. ARCHETYPE (with citations).

Literature: PLATO, *Rep.*, 379, 380 c, 388 b; ARISTOTLE, *De An.*, II. i. 413 a 9. (J.M.B.)

Type and Typical (in aesthetics). A concrete embodiment or exemplification of a characteristic quality.

Usually, the embodiment of a quality conceived to be characteristic of a species or group; hence, the ideal representative of a species or group. So the Greek gods as represented in sculpture were types of the various qualities characteristic of the Greek ideal world of intelligence and order.

The formation of a type by an artist (or people) may take any one of three methods: (1) the accidental may be neglected and only the central emphasized; or (2) this may be pushed further and the complex reduced to the simple, as a character in literature may be simply avarice personified; or (3) a certain average or normal example may be sought, as if to portray what nature seems to be aiming at in the species in question. See IDEAL, and IDEALIZATION.

Literature: VOLKELT, *Aesth. Zeitfragen* (1895), 134 ff.; BROWN, *Fine Arts* (1891), 54-70; SANTAYANA, *Sense of Beauty* (1896), 112-63; HERCKENRATH, *Problèmes d'Esthétique et de Morale* (1898), 1-66. (J.H.T.)

Type (and **Typology**) (in theology). An object in the Old Testament dispensation which symbolized or prefigured something in the Christian dispensation; the former is called also the 'prototype' of the latter.

Typology is the system of such symbols and prefigurations as are found in the Old Testament. The Paschal Lamb, for example, symbolizes the sacrifice of Christ in the new dispensation, and more specifically the Sacrament of the Eucharist, which has taken its place.

Literature: HILLER, *Neues Syst. alter Vorbilder* (1858); HOFMANN, *Wahrsagung und Erfahrung* (1841); ED. BÖHMER, *Die Offenbarung* (1855). (A.T.O.)

Types (mental): Ger. (*Gemüths*-, &c.) *Typen*, *geistige Eigenarten*; Fr. *types mentaux*; Ital. *tipi mentali*. A term employed in VARIATIONAL PSYCHOLOGY (q. v.) to designate certain well-marked differences of mental constitution, or certain modes of mental functioning, which characterize groups of individuals. The characters are thus 'typical' rather than 'individual.' (E.B.T.-J.M.B.)

Thus we speak of the adolescent type, the criminal type, the South German type, &c.

TYPE-THEORY

Since, however, 'individuality' or 'character' or 'personality' forms a whole of great complexity, it is better to narrow the use of the word 'type' to a single department of the mental life. We then have 'memory types,' 'types of volition,' 'emotional types,' &c.

As an instance of the use of 'type' in a broad sense, we may cite Stern's classification of the observers in the psychological laboratory as 'objective' (yielding themselves to the stimulus) and 'subjective' (expectant, suggestive); *Zeitsch. f. Psychol.*, xxii. (1899) 13; cf. Bolton, *Amer. J. of Psychol.*, vi. (1893) 208. Stern distinguishes, in the narrower sense, types of sensitivity, of 'thought' (*Anschauung*; the ordinary 'memory type'), of memory, of association, of apprehension, of attention, of power of combination, of judgment, of reaction, of feeling, of mental *tempo*, and of mental energy. See his work, *Ueber Psychol. d.*

individuellen Differenzen (1900, with a bibliography of 190 titles); Titchener, *Exper. Psychol.*, i. Pt. II. xxv. ff., 387 ff. (E.B.T.)

The theory of mental types owes much of its development to the work of the pathologists, notably the French investigators of SPEECH AND ITS DISORDERS (q.v.). They have found differences in the brain mechanism of speech and its localization according to the type of preferred function of the individual (see the literature of APHASIA and of INTERNAL SPEECH). Various tests have also been devised for determining an individual's type (see TESTS, psychophysical). Attempts have been made to base methods of instruction upon the type differences of children (see e.g. the writer's *Story of the Mind*, chap. viii). Cf. TEMPERAMENT, and REACTION TIME. (J.M.B.)

Type-theory (of reaction): see REACTION TIME, *passim*.

U

UBICATION — ULTIMATE

Ubication [Lat. *ubicatio*, from *ubi*, where]: Ger. and Fr. the same; Ital. *ubicazione*. A term of scholastic philosophy to express the placing of an entity.

It includes minds in its reference as well as bodies; in the former sense it signifies the point where mind is regarded as acting on body. See Harper, *The Metaphysics of the School*, 413-4. (J.D.)

Ubiquity [Lat. *ubique*, everywhere, from *ubi*, where, through Fr.]: Ger. *Allgegenwart* (omnipresence); Fr. *ubiquité*; Ital. *ubiquità*. (1) Presence in an indefinite number of places at the same time.

(2) OMNIPRESENCE (q. v.). (J.M.B.)

Ugly [Icel. *uggligr*, fearful, dreadful]: Ger. *hässlich*; Fr. *laide*; Ital. *laido*. Applied to that which is aesthetically repellent or offensive. (J.R.A.—J.M.B.)

The relation of the ugly to beauty and its right to a place in aesthetic experience have been questions of constantly increasing interest to aestheticians. Aristotle admitted the ugly in painting, as did Plutarch; the latter because of the admiration aroused for the skill of the artist, the former because of the interest and pleasure felt by the spectator in the recognition of the object represented. Plotinus, regarding beauty as the intrinsically rational, excluded the ugly as the irrational, leaving open the question whether in reality anything is absolutely irrational and so really ugly. Augustine admits the ugly as enhancing by its apparent contrast the richness and harmony of beauty. Modern writers in aesthetics have accorded the ugly relatively much more attention than did the ancients. The general tendency has been away from the doctrine of the purely ugly as a mere

foil and counterpart of beauty or an incidental element in aesthetic experience, towards a recognition of it as a feature without which art could not be true to life in its larger meaning, and could not adequately present the intrinsic rationality of a world like ours, in which so much of irrationality inheres. (Thus Rosenkranz, writing under the influence of Kant and Hegel; also from an antithetic standpoint, Hartmann.) In its character as disagreeable, the ugly is generally recognized as entering legitimately into the conflicts involved in the tragic and the comic, occurring also in the plastic forms closely related to the comic, e. g. the grotesque and fantastic.

Literature: BOSANQUET, *Hist. of Aesthetic* (1892); HARTMANN, *Aesthetik*, i (1886), ii (1887); ROSENKRANZ, *Aesthetik d. Hässlichen* (1853). (J.R.A.)

Ulrici, Hermann. (1806-84.) Born at Pforten, in Brandenburg, Germany, he was educated in law at Halle and Berlin. After 1829 he studied philosophy, and (1834) became professor of philosophy at Halle, where he died. He was for many years editor of the *Zeitsch. f. Philos. u. philos. Kritik*.

Ultimate [Lat. *ultimus*, furthest]: Ger. *allerletzt*, *End-(glied, &c.)*; Fr. *dernier*, *ultime*, *final*; Ital. *ultimo*. (1) Last in a series; especially, in a series of purposes each, except the last, subsidiary to an *ulterior* one following it in the arrangement considered, or of actions each of which, except the last, leads to the performance of another.

Thus, the phrase *ultimate signification* implies that a sign determines another sign of the same object, and this another; and so on until something is reached which is a sign only for itself. *Ultimate fact* implies that

there is a series of facts each explicable by the one following it, until a fact is reached utterly inexplicable. (Cf. Hamilton's *Reid*, Note A, § 5, II vi. et seq.).

(2) Applied also to the limiting state of an endless series of states which approach indefinitely near to the limiting state, and on the whole nearer and nearer, without necessarily ever reaching it; although the word ultimate does not imply a denial of actual attainment.

Thus, it has been held that a real object is that which will be represented in the ultimate opinion about it. This implies that a series of opinions succeed one another, and that it is hoped that they may ultimately tend more and more towards some limiting opinion, even if they do not reach and rest in a last opinion. Cf. TRUTH AND ERROR, Logical. (C.S.P.)

Ultra- [Lat. *ultra*, beyond]. Extreme; used in compounds, as ultra-sensational, ultra-idealism, &c. (J.M.B.)

Ultramontanism [Lat. *ultramontanus*, beyond the mountain]: Ger. *Ultramontanismus*; Fr. *ultramontanisme*; Ital. *ultramontanismo*. In the Roman Catholic Church, the principles and tendencies of those who aim to increase and consolidate the power of the pope, and especially to maintain his temporal power intact.

Ultramontanism is opposed to GALRICANISM (q.v.) and constitutes a centralizing tendency in the Church. The dogma of the infallibility of the pope was regarded as a triumph of the Ultramontane influence. In recent years Ultramontanism and Gallicanism have lost a large measure of their party significance and have come to stand for opposing tendencies within the Catholic Church. (A.T.O.)

Unbelief (religious): Ger. *Unglaube*; Fr. *incrédulité*; Ital. *miscredenza*. That attitude of mind towards religion which is not simply negative but involves positive disbelief of some of the doctrines or practices of religion.

Unbelief presupposes the positive rejection of the claims of religion, and in the minds of most religious persons is associated with a degree of moral obliquity. In the popular mind it is identified with infidelity. Cf. BELIEF (especially in theology and religion). (A.T.O.)

Unconditional: see ABSOLUTE, and CONDITIONED.

Unconscious: Ger. *unbewusst*; Fr. *inconscient*; Ital. *inconscio*, *incosciente*. (1) In general, not conscious, non-mental; not possessed of mind or consciousness.

The word is thus used, in psychology, of bodily states in or during which consciousness lapses. So James speaks of 'sleep, coma, fainting, epilepsy, and other unconscious conditions' (*Princ. of Psychol.*, i. 199).

(2) The word is sometimes used, in experimental psychology, to cover psychophysical (i.e. presumably cortical) processes which, for various reasons, lack their normal conscious correlates.

This use is not well defined; the following instances will, however, illustrate it fairly well. (a) A lecturer goes on the platform with a severe neuralgia. He 'forgets' the pain in the excitement of his topic; but the neuralgia 'returns' at the conclusion of his address (W. B. Carpenter, *Princ. of Mental Physiol.*, 1888, 6th ed., 138 f.). (b) 'All the separately imperceptible overtones of a clang contribute something . . . to the perception of the whole; and the sum of these contributions constitutes what we call clang-tint.' This 'co-operation of unnoticed components in the total effect of a connection of conscious processes' is characteristic of fusion and of attention (O. Külpe, *Outlines of Psychol.*, Eng. trans., 1895, 290 f.). (c) Fechner's experiment. Hold a tuning-fork to the ear, until the tonal sensation has entirely ceased. Remove the fork: the silence is deeper than before. Bring the fork to the ear again: a faint tone may be heard.

(3) Specifically, a postulate of the Herbartian psychology. 'Unconscious mental excitations (*seelische Erregungen*), of whose nature we are ignorant, are interposed between our conscious ideas; every conscious idea arises out of, and dies away into, such an unconscious excitation' (T. Lipps, *Grundthatsachen des Seelenlebens*, 1883, 125 ff.; cf. *Ber. u. d. 3. int. Cong. f. Psychol.*, 1897, 146 ff.).

Historically important are (a) the doctrine of unconscious cerebration (Hamilton, Carpenter, J. S. Mill; see Carpenter's *Mental Physiol.*, 515 ff.), and (b) the more specific Helmholtzian doctrine of unconscious inference (*Physiol. Optik*, 2nd ed., 602, 962).

For a general discussion of the 'unconscious' in psychology see Baldwin, *Senses and Intellect*, 1890, 45-58, 68; Höfler, *Psychologie*, § 43, 270 ff. (E.B.T.)

Unconscious (the, philosophy of): Ger. *Philosophie des Unbewussten*; Fr. *philosophie de l'inconscient*; Ital. *filosofia dell' Inconscio*. The metaphysical system of E. v. Hartmann, by whom the absolute principle is called 'the Unconscious.'

'According to v. Hartmann (*Philos. d. Unbewussten*, 3) the unconscious is the absolute principle, active in all things, the force which is operative in the inorganic, organic, and mental alike, yet not revealed in consciousness (ibid., 365). It is the unity of unconscious presentation and will (ibid., 380) of the logical (idea) and the alogical (will). The unconscious exists independently of space, time, and individual existence, timeless before the being of the world (ibid., 376). For us it is unconscious, in itself it is superconscious (überbewusst)' (cf. Eisler, *Wörterb. d. philos. Begriffe*, 'Unbewusst'). (J.M.B.)

Unconscious Mental States. Supposed factors of experience which are not discoverable as states of consciousness. Cf. UNCONSCIOUS, SUBCONSCIOUS, and UNCONSCIOUS (the, philosophy of).

Literature: see UNCONSCIOUS; also HAMILTON, *Lects. on Met.*; TAINE, *Intelligence*; RABIER, *Leçons de Psychol.* (J.M.B.)

Unconscious Selection: see SELECTION (in biology), and ARTIFICIAL SELECTION.

Unconscious State (in pathology): Ger. *unbewusster Zustand*; Fr. *état inconscient*; Ital. *incoscienza, stato incosciente* (or *inconscio*), *inconsapevolezza* (E.M.). A condition of little or no consciousness.

Abnormal deviations from ordinary conditions of consciousness are of various kinds, degree, and import. They may be roughly distinguished according as there is an absence or abeyance of consciousness, a subnormal degree of consciousness, or a marked modification of consciousness; but such distinction cannot be consistently maintained, as many conditions present variations from the normal in more than one of these respects. In general, sleep or drowsiness, the action of a hypnotic, a faint, illustrate the kind of change referred to in the first; hypnotic suggestion, reverie, ecstasy, that of the second; and changes of personality, hysteria, mania, delusions, that of the third group. (For descriptions of these see especially SLEEP, DREAMS, HYPNOSIS, TRANCE, PERSONALITY (alterations of), and HALLUCINATIONS.) In a strict sense unconsciousness refers to the absence of consciousness, but the actual use includes all subconscious states, or those in which there is a limited sensitiveness to ordinary impressions. Normal states of subconsciousness may thus be found in a condition of abstraction, reverie, 'absent-mindedness,' the transition from sleep to wakefulness, while profound sleep represents normal unconsciousness. As

more or less abnormal instances of subconscious states may be cited somnambulism, certain forms of trance, the condition resulting from slight doses of certain drugs (see PSYCHIC EFFECT OF DRUGS), while unconsciousness appears in deep narcosis, stupor, faint, coma, &c. Cf. SUBCONSCIOUS, and UNCONSCIOUS.

In true insanity unconscious states appear in the profound self-absorption of melancholia, while in the mental condition of idiocy or dementia there is an insensibility to outer impressions of different origin but like appearance. (J.J.)

Understanding and Reason: Ger. *Verstand und Vernunft*; Fr. *entendement et raison*; Ital. *intendimento e ragione*. This pair of correlative terms is used to distinguish two forms of knowledge, one of which, UNDERSTANDING (q.v.), is discursive, and hence based on premises and hypotheses themselves not subjected to reflection, while the other, REASON (q.v.), apprehends in one immediate act the whole system, both premise and inference, and thus has complete or unconditioned validity.

Accordingly, to those who hold to this distinction, the understanding is the instrument of scientific knowledge, the reason the instrument of philosophic. The need of the distinction was felt as early as Plato. He defines the comprehensive and self-sufficing knowledge as *νόσις* (see NOUS); the conditional as *διάνοια*—reflective, 'knowing through' another, and hence mediate (*ἐπιστήμη* is used differently, sometimes as including both; sometimes as reflective or mediate; sometimes as original and intuitive). Aristotle uses the term *νόσις* in the same sense, with a more technical consideration of the axiomatic or self-evident. For mediate knowledge which yet arrives at certainty (as distinct from that of mere probability, *δόξα*, OPINION, q.v.), he uses the term *ἐρένη* (this is empirical knowledge, plus a knowledge of its reason or ground. As pointed out by Erdmann, *Hist. of Philos.*, i. 134, the use of this term meaning also 'art,' as against the *διάνοια* of Plato, is due to the fact that mathematics is its type to Plato, while to Aristotle it is trained skill, like that of the physician. It is experience rationalized).

The Neo-Platonic thinkers, here as elsewhere, multiply distinctions; but, in essence, they are true to Plato. Scholasticism keeps the ideas, and derives its terms from Boethius (Eucken, *Philos. Terminol.*, 59). *Intellectus*

is synonymous with *noesis*, and *ratio* with reflective knowledge. (Hence the ambiguity of 'reason' in English: meaning often reasoning, or reflective thought, and less often intuitive and certain knowledge; *raison* in French is so filled with the concept of logical process that it is hardly fit at all to translate the German *Vernunft*.) But the significance of the modern distinction is due to Kant. The understanding is thought working according to the schematized categories, and so having validity in relation to experience; reason is thought working without reference to the application of concepts to the material of sense, hence soaring into the supersensuous, and so, while giving us certain ideals of a regulative value, sharing no positive (or constitutive) worth. Coleridge made much of the distinction in English, but without any regard to Kant's careful and critical limitations. Hegel developed the ideas so that reason should express a knowledge which is immediate in certainty and grasp, but the result of the development of the understanding to its full implications (*Lesser Logic*, chap. vi). See SPECULATION. He seems to follow Nicholas of Cusa, who defines understanding as distinguishing and naming, separating opposites according to the principle of contradiction, and reason as that which recognizes the compatibility of opposites. (J.D.)

Under-statement: Ger. *Unteraussage*; Fr. *jugement subordonné, proposition subalterne*; Ital. *subalterna* (or *subordinata*) *proposizione*. A proposition derived from another as an immediate inference, but not equivalent to it; the proposition *q*, if *p* implies *q*, but *q* does not imply *p*.

Thus *No a is both b and c* is an under-statement to *No a is b*; it states only half as much, for *No a is b* affirms that *No a is bc* and also that *No a is b̄c̄*. From *Whoever breaks, pays*, we can infer *Some who break (if there are any who break) pay*, but not conversely. (C.L.F.)

Undertaker: see ENTREPRENEUR.

Undulation: see VIBRATION.

Unfitness: Ger. *Unangemessenheit*; Fr. *disconvenance* (most general and most philosophical term in use—T.F.); Ital. *incapacità*. See FIT, and FITNESS (various topics).

Unicellular Organisms: Ger. *einzelige Organismen*; Fr. *organismes unicellulaires*; Ital. *organismi unicellulari*. Living creatures of a single cell.

They comprise the unicellular animals (the

PROTOZOA, q. v.), unicellular (Protophytic) plants, and the undeveloped ovules of the (multicellular) METAZOA (q. v.). Cf. AMOEBA for certain details. Interesting work has been done in investigating the behaviour of unicellular organisms under various experimental conditions, for which see the literature.

Literature: DAVENPORT, Compar. Morphol.; JENNINGS, series of papers, i-vii, in the Amer. J. of Physiol., 1899 ff.; CALKINS, The Protozoa (1901). (J.M.B., E.B.P.)

Unification of Knowledge: not in use in other languages. A phrase used by Herbert Spencer to define philosophy. He distinguishes three stages of knowledge. The first is ordinary unscientific knowledge, in which each fact stands detached and unconnected. It is ununified. Science generalizes related truths of various departments, but does not attempt to bring these generalizations into a single whole. It is partially unified knowledge. 'The truth of philosophy bears the same relation to the highest scientific truths that each of these bears to lower scientific truths. . . . It is completely unified knowledge.' That is, it takes the generalizations of, say, physics, psychology, and sociology, and reduces them to special cases of a still more general law. In Spencer's theory this highest generalization, through which knowledge is completely unified, is that of evolution and dissolution considered as the formula of the redistribution of matter and motion, and derived from the persistence of force (*First Princ.*, Pt. II. chap. i; see also Guthrie, *On Spencer's Unification of Knowledge*). (J.D.)

Uniformitarianism: Ger. (*Theorie der Stetigkeit der Naturentwicklung*; Fr. *naturalisme unitaire* (not exact—T.F.); Ital. (*dottrina di*) *uniformità di Natura* (E.M.). The theory that the world as a whole, including the mental and moral, is (1) the outcome of a single system of forces, or (2) the realization of a single principle or law operative without breaks and without interference from without. Cf. UNIFORMITY (2), (3), (4), and CONTINUITY.

This view is often hit off by the motto *Natura non facit saltum*. The term has come into wider use since the rise of the doctrine of evolution, on the one hand, and the philosophy of Hegel, on the other hand. It is a point of view common to naturalism, idealism, and monism; but it is opposed to occasionalism, supernaturalism, and dualism (in metaphysics). (J.M.B., G.F.S.)

Uniformity [Lat. *unus*, one, + *forma*, shape]: Ger. *Ein- (or Gleich-) förmigkeit*;

Fr. *uniformité*; Ital. *uniformità*. (1) A fact consisting in this: that, of a certain genus of facts, a proportion approaching unity (the whole) belong, in the course of experience, to a certain species; so that, though of itself the knowledge of this uniformity gives no information concerning a certain thing or character, yet it will strengthen any inductive conclusion of a certain kind.

It is, therefore, a high objective probability concerning an objective probability. There are, in particular, four classes of uniformities, the knowledge of any of which, or of its falsity, may deductively strengthen or weaken an inductive conclusion. These four kinds of uniformity are as follows:—

i. The members of a class may present an extraordinary resemblance to one another in regard to a certain line of characters. Thus, the Icelanders are said to resemble one another most strikingly in their opinions about general subjects. Knowing this, we should not need to question many Icelanders, if we found that the first few whom we met all shared a common superstition, in order to conclude with considerable confidence that nearly all Icelanders were of the same way of thinking. Philodemus insists strongly upon this kind of uniformity as a support of induction.

ii. A character may be such that, in whatever genus it occurs at all, it almost always belongs to all the species of that genus; or this uniformity may be lacking. Thus, when only white swans were known, it would have been hazardous to assert that all swans were white, because whiteness is not usually a generic character. It is considerably more safe to assert that all crows are black, because blackness is oftener a generic character. This kind of uniformity is especially emphasized by J. S. Mill as important in inductive inquiries.

iii. A certain set of characters may be intimately connected so as to be usually all present or all absent from certain kinds of objects. Thus, the different chemical reactions of gold are so inseparable that a chemist need only to succeed in getting, say, the purple of Cassius, to be confident that the body under examination will show every reaction of gold.

iv. Of a certain object it may be known that its characteristic is that when it possesses one of a set of characters within a certain group of such sets, it possesses the rest. Thus, it may be known of a certain man that to whatever party he belongs, he is apt to

embrace without reserve the entire creed of that party. We shall not, then, need to know many of his opinions, say in regard to politics, in order to infer with great confidence his position upon other political questions.

(2) The word 'uniformity' plays such a singular and prominent rôle in the logic of J. S. Mill that it is proper to note it. He was apt to be greatly influenced by Ockham's razor in forming theories which he defended with great logical acumen; but he differed from other men of that way of thinking in that his natural candour led to his making many admissions without perceiving how fatal they were to his negative theories. In addition to that, perhaps more than other philosophers, in endeavouring to embrace several ideas under a common term, he often leaves us at a loss to find any other character common and peculiar to those notions except that of their having received from him that common designation. In one passage of his *System of Logic* (1842), he declares, in reference to the difference in strength between two inductive conclusions, that whoever shall discover the cause of that difference will have discovered the secret of inductive reasoning. When, therefore, he shortly afterwards points out that the distinction between those two inductions is that one of them is supported by a uniformity of the second of the above four classes, while the other is met by a distinct diversity of the same kind, and when he himself gives to that uniformity this designation when he afterwards declares that the validity of induction depends upon uniformity, his reader naturally supposes he means uniformity in that sense. But we find that he employs the word for quite another purpose. Namely, he does not like the word *law*, as applied to an inductive generalization of natural facts—such as the 'law' of gravitation—because it implies an element in nature, the reality of a general, which no nominalist can admit. He, therefore, desires to call the reality to which a true universal proposition about natural phenomena corresponds, a 'uniformity.' The implication of the word, thus used, is that the facts are, in themselves, entirely disconnected, and that it is the mind alone which unites them. One stone dropping to the earth has no real connection with another stone dropping to the earth. It is, surely, not difficult to see that this theory of uniformities, far from helping to establish the validity of induction, would be, if consistently admitted, an insuperable objection to such validity.

For if two facts, *A* and *B*, are entirely independent in their real nature, then the truth of *B* cannot follow, either necessarily or probably, from the truth of *A*. If I have tried the experiment with a million stones and have found that every one of them fell when allowed to drop, it may be very natural for me to believe that almost any stone will act in the same way. But if it can be proved that there is no real connection between the behaviour of different stones, then there is nothing for it but to say that it was a chance coincidence that those million stones all behaved in the same way; for if there was any reason for it, and they *really* dropped, there was a *real reason*, that is, a real general. Now, if it is mere chance that they all dropped, that affords no more reason for supposing that the next will drop, than my throwing three double-sixes successively with a pair of dice is a reason for thinking that the next throw will be double-sixes.

(3) But now we find that Mill's good sense and candour will not allow him to take the course which a Hobbes would have taken, and utterly deny the validity of induction; and this leads to a new use of the word *uniformity*, in which he speaks of the 'uniformity of nature.' Before asking exactly what this phrase means, it may be noted that, whatever it means, the assertion of it is an assent to scholastic realism, except for a difference of emphasis. For to say that throughout the whole course of experience, events always, or even only usually, happen alike under the same conditions (what is usually called the 'invariability' of nature), is to assert an agreement (complete or partial) which could not be ascribed to chance without self-contradiction. For chance is merely the possible discrepancy between the character of the limited experience to which it belongs and the whole course of experience. Hence, to say that of the *real*, objective facts some *general* character can be predicated, is to assert the reality of a general. It only differs from scholastic realism in that Mill and his followers treat this aspect of the matter lightly—that is to say, the objective reality of the general—while the Scholastics regarded it as a great and vital feature of the universe. Instead of 'uniformity' now importing that what others call 'laws' are fabrications of the human mind, this 'uniformity of nature' is erected by Mill into the greatest of laws and absolutely objective and real.

Let us now inquire what the 'uniformity

of nature,' with its synonymous expressions that 'the future resembles the past,' and so forth, can mean. Mill says that it means that if all the circumstances attending two phenomena are the same, they will be alike. But taken strictly this means absolutely nothing, since no two phenomena ever can happen in circumstances precisely alike, nor are two phenomena precisely alike. It is, therefore, necessary to modify the statement in order to give it any meaning at all; and it will be found that, however it may be so modified, the moment it begins to carry a definite meaning, one of three things results: it becomes either, first, grossly false, or, second, an assertion which there is really no good reason to believe even approximately true, or thirdly, it becomes a quasi-subjective truth, not lending any colour of validity to induction proper. If, for example, we were to say that under any given species of circumstances presenting any similarity, phenomena of any given genus would be found to have a specific general resemblance in contrast with the specific character of phenomena of the same genus occurring under a different species of circumstances of the same genus, this would be monstrously false, whether intended as an absolutely universal proposition or merely as one approximately true. Let, for example, the genus of phenomena be the values of the throws of a pair of dice in a given series of successive throws indefinitely continued. Let the first species of circumstances be that the ordinal number of a throw in the series is *prime*. It is pretty certain that there would be no general character in the corresponding values of throws to distinguish them from those which would result when the ordinal number is divisible by 2, or by 3, or by any other prime. It thus appears that when we take *any* genus of circumstances, the law turns out false. Suppose, then, that we modify it by saying that, taking any genus of phenomena and separating this into two species, there will be found in the discoverable circumstances *some* general resemblance for all those attending phenomena of the same species in contrast to those attending phenomena of the other species. This is a proposition which there is not the slightest reason to believe. Take, for example, as the genus of phenomena, the many thousands of Latin descriptions of American species of plants by Aca Gray and his scholars. Now consider the species of this genus of phenomena which agree in this respect, that the

two first words of the description have their first vowels the same. There is no reason to suppose that there was any general respect in which the circumstances of that species of the genus of phenomena agree with one another and differ from others, either universally or usually. It is a mere chance result. It is true that some persons will not be inclined to assent to this judgment; but they cannot prove it otherwise. It can afford no adequate basis for induction. We see, then, that when we consider *all* phenomena, there is no way of making the statement sufficiently definite and certain. Suppose, then, that we attempt still another modification of the law, that, of *interesting* resemblances and differences between phenomena, some considerable proportion are accompanied by corresponding resemblances and differences between those of the circumstances which appear to us to be *pertinent*. The proposition is now rather psychological than metaphysical. It would be impossible, with any evidentiary basis, to strengthen the expression 'some considerable proportion'; and in other respects the statement is vague enough. Still, there is sufficient truth in it, perhaps, to warrant the presumptive adoption of hypotheses, provided this adoption merely means that they are taken as sufficiently reasonable to justify some expense in experimentation to test their truth by induction; but it gives no warrant at all to induction itself. For, in the first place, induction needs no such dubious support, since it is mathematically certain that the general character of a limited experience will, as that experience is prolonged, approximate to the character of what will be true in the long run, if anything is true in the long run. Now all that induction infers is what would be found true in the usual course of experience, if it were indefinitely prolonged. Since the method of induction must generally approximate to that truth, that is a sufficient justification for the use of that method, although no definite probability attaches to the inductive conclusion. In the second place, the law, as now formulated, neither helps nor hinders the validity of induction proper; for induction proper consists in judging of the relative frequency of a character among all the individuals of a class by the relative frequency of that character among the individuals of a random sample of that class. Now the law, as thus formulated, may tend to make our hypothesis approximately true; but that advantage has been gained before the

operation of induction, which merely tests the hypothesis, begins. This inductive operation is just as valid when the hypothesis is bad as when it is good, when the character dealt with is trivial as when it is interesting. The ratio which induction ascertains may be nearer $\frac{1}{2}$, and more remote from 1 or 0, when the characters are uninteresting; and in that case a larger number of instances will usually be requisite for obtaining the ratio with any given degree of precision (for if the ratio is really 1 or 0, it will be almost a miracle if in the sample it is far from that ratio, although this will not be impossible, if the whole class is infinite), but the essential validity of the process of induction remains unaffected by that circumstance.

What is usually meant by the uniformity of nature probably is that in proportion as the circumstances are alike or unlike, so are any phenomena connected with them alike or unlike. It may be asked to what degree nature is uniform in that sense. The only tenable answer is that it is as little uniform as it possibly could be imagined to be; for were any considerable proportion of existing uniformities, or laws, of nature destroyed, others would necessarily thereby result.

In fact, the great characteristic of nature is its diversity. For every uniformity known, there would be no difficulty in pointing out thousands of non-uniformities; but the diversities are usually of small use to us, and attract the attention of poets mainly, while the uniformities are the very staff of life. Hence, the higher and wider are our desires, the greater will be the general impression of uniformity produced upon us by the contemplation of nature as it interests us.

(4) There are senses in which nature may not irrationally be held to be uniform; but opinions differ very widely as to the extent and nature of this uniformity. The chief of these are as follows:—

(a) The majority of physicists, at least of the older generation, hold, with regard to the physical universe, that its elements are masses, their positions, and the variations of these positions with time. It is believed that every motion exactly obeys certain laws of attraction and repulsion; and there is no other kind of law, except that each atom or corpuscle is a centre of energy arranged in equipotential surfaces about it, which follow a regular law; and that this is a permanency. But the equations of motion are differential equations of the second order, involving,

therefore, two arbitrary constants for each moving atom or corpuscle, and there is no uniformity connected with these constants. At least, no such uniformity is, with the least probability, discoverable. As for the distribution of potential about an atom or corpuscle, it is regular; but there is no ulterior reason for that regularity, or, at least, none is probably discoverable. What is absolutely beyond discovery, whether direct and specific or indirect and general, may be considered to be non-existent.

From this usual and in some sense standard opinion there are many divergences in both directions. First, in the direction of greater uniformity.

(b) Some hold that there is some exact uniformity in the arbitrary constants of the motion of the atoms, so that, for example, perhaps at some initial instant they all had some symmetrical or regular arrangement, like a pack of cards unshuffled; and that the velocities at that instant were regular also. But this regularity being of a purely aesthetic or formal kind, and the laws of motion equally formal and unrelated to any purpose, it follows that all kinds of arrangements will be produced, ungoverned by any uniformity, but mere effects of chance. Three stars may, for example, at some instant form an equilateral triangle; but there would be no particular reason for this: it would be merely a casual coincidence.

(c) Others go further and maintain that the constants of position and velocity are subject to a law not merely formal, but are governed by final causes in such a way that there is no arrangement or coincidence whatever which was not specially intended by the Creator. To this theory, such words as *providence* and *fore-knowledge* are ill adapted; because the two constants which each atom or corpuscle has, remain constant throughout all time, and ought not to be considered as having been fixed at any particular epoch. The very idea is that the arrangement is determined by what would be the result of different arrangements at each period of time. If, for example, a given prayer effects rain, it must be supposed that in view of that prayer, and as its consequence, the different atoms had the appropriate constants; but that these were not given to the atoms at any particular epoch, being permanent values. Any intentional action on the part of a free agent is to be explained in the same way. If an agent is to be supposed really free, it is difficult to

see what other physical explanation is compatible with the exactitude of law. This seems to be substantially the notion of most of those who have supported free-will.

On the other hand, many philosophers suppose a less degree of uniformity in nature than is supposed in opinion (a). Of these the following have come to the present writer's notice as being actually defended.

(d) Some suppose that while law is absolute, yet there are constantly arising cases analogous to unstable equilibrium in which, owing to a passage of a velocity through infinity or otherwise, the law does not determine what the motion shall be. Thus if one Boscovichian point attracts another inversely as the square of the distance, and they move in one straight line, then when they come together they may move through one another, or move backwards on the same line, or may separate along any other line, without violating the differential equation. Such 'singularities,' as the mathematicians say, are theoretically possible; and may be supposed to occur very often. But to suppose that free action becomes possible in such a way is very illogical. In the first place, it supposes a direct interaction between 'mind' and matter; infinitesimal, no doubt, but none the less real. Why not better suppose a slight but finite action of this kind, and so avoid the following objections? Namely, in the second place, this is to put faith, not scientific credence, in the inductive laws of matter infinitely beyond what induction can ever warrant. We know very well that mind, in some sense, acts on matter, and matter on mind: the question is *how*. It is not in speculations of this fanciful kind that the true answer is likely to be found. In the third place, although this speculation wanders so far beyond all present knowledge, it nevertheless comes into conflict with a legitimate induction, namely, the supposition of any real 'singularity' or breach of continuity in nature is in as distinct conflict with all our knowledge as is a miracle.

(e) Sundry far less tenable hypotheses of lacunae between inviolable laws have often been proposed. One opinion frequently met with is that the law of energy does not prescribe the direction of velocity, but only its amount; so that the mind may cause atoms to 'swerve,' in regular Lucretian fashion. This singular notion has even been embraced by mathematicians, who are thinking of a projectile shot into a curved tube, or other case of an equation of condition. Of course,

if mind can construct absolute constraints, it can much easier exert force that is finite. Other writers suppose lacunae, without telling us of what particular description they are; they seem to think law is absolute as far as it goes, but that its jurisdiction is limited.

(f) Much more philosophical and less logically objectionable is the notion of St. Augustine and others (it is near to the opinion of Aristotle) that the only fundamental kind of causation is the action of final causes, and that efficient causation is, in all cases, secondary. Accordingly, when a miracle occurs there is no violation of the real *cursus naturae*, but only of the apparent course of things.

(g) The hypothesis suggested by the present writer is that all laws are results of evolution; that underlying all other laws is the only tendency which can grow by its own virtue, the tendency of all things to take habits. Now since this same tendency is the one sole fundamental law of mind, it follows that the physical evolution works towards ends in the same way that mental action works towards ends, and thus in one aspect of the matter it would be perfectly true to say that final causation is alone primary. Yet, on the other hand, the law of habit is a simple formal law, a law of efficient causation; so that either way of regarding the matter is equally true, although the former is more fully intelligent. Meantime, if law is a result of evolution, which is a process lasting through all time, it follows that no law is absolute. That is, we must suppose that the phenomena themselves involve departures from law analogous to errors of observation. But the writer has not supposed that this phenomenon had any connection with free-will. In so far as evolution follows a law, the law of habit, instead of being a movement from homogeneity to heterogeneity, is growth from difformity to uniformity. But the chance divergences from law are perpetually acting to increase the variety of the world, and are checked by a sort of natural selection and otherwise (for the writer does not think the selective principle sufficient), so that the general result may be described as 'organized heterogeneity,' or better rationalized variety. In view of the principle of continuity, the supreme guide in framing philosophical hypotheses, we must, under this theory, regard matter as mind whose habits have become fixed so as to lose the powers of forming them and losing them,

while mind is to be regarded as a chemical genus of extreme complexity and instability. It has acquired in a remarkable degree a habit of taking and laying aside habits. The fundamental divergences from law must here be most extraordinarily high, although probably very far indeed from attaining any directly observable magnitude. But their effect is to cause the laws of mind to be themselves of so fluid a character as to simulate divergences from law. All this, according to the writer, constitutes a hypothesis capable of being tested by experiment.

Literature: besides most treatises on LOGIC (q. v., especially inductive) see RENOUVIER and PRAT, *La nouvelle Monadologie* (1899). (C.S.P.)

Uniformity (notion of). The objective regularity and orderliness presupposed in the possibility of representing the real world by an ideal construction. 'Whenever any two or more attributes are repeatedly to be connected together, closely or remotely in time or in space, there we have a uniformity. And the general expression, the uniformity of nature, is intended to cover all such partial connections, and to imply that their existence may be detected or reasonably inferred throughout all phenomena whatever' (Venn, *Empirical Logic*, 93).

All contrivance of means towards ends, and indeed all adjustment of action in accordance with previous experience, presupposes as the condition of effectiveness more or less uniformity of coexistence and sequence in natural phenomena. Practical needs lead us to seek for uniformities, and the world is so constituted that we find them. With the development of experience these uniformities assume the form of a system, and a theoretical interest arises in the extension of this system. Finally, the conception of natural process as determined, everywhere and in every minutest detail, by fixed laws comes into being.

(G.E.S., J.M.B., C.L.F.)

Uniformity of Nature: see UNIFORMITY (3, 4).

Unison [Lat. *unus*, one, + *sonus*, sound]: Ger. *Einklang*; Fr. *unisson*; Ital. *unisono*. The most perfect chord, in which both tones have the same pitch. See Helmholtz, *Sensations of Tone* (Eng. trans.), 187. (E.B.T.)

Unit (of physical measurement) [Lat. *unitas*]: Ger. *Einheit*; Fr. *unité*; Ital. *unità*. A portion of any magnitude or quantity employed to express the value of any other portion *P* of the same magnitude or quantity

by stating the ratio of P to the unit. Cf. MEASUREMENT.

If P contains the unit an integral number of times, the ratio is that number. If P and the unit are commensurable, the ratio may be expressed by subdividing the unit into a number n of such parts that P shall contain a part an exact number of times. If m is this number, the ratio is then expressed by the fraction $\frac{m}{n}$. If P and the unit are incom-

mensurable, a fraction can still be found which shall express the ratio with an error as small as we choose to make it, by increasing the number of parts, because the error will always be less than one-half a part.

The ratios which thus fix the values of quantities are ordinarily expressed by algebraic literal symbols, a, b, c , &c. In order that they may have any meaning, the unit must be of the same kind as the quantity to be expressed. There can be no ratio between quantities of unlike kinds, as a *day* and a *mile*.

Apart from this condition, the magnitude of a unit is arbitrary. But the choice may be so made as to simplify investigation; indeed, an important factor in the advance of physics has been the definition of a clear and simple system of units. In this system a limited number of quantities, generally three, have arbitrary units assigned them, and the units of all other quantities are defined in terms of these in such ways as to simplify the expression of results to be obtained. These are called *derived units*.

In physics there are three arbitrary units called fundamental:

- (a) That of *length*, represented by the symbol L ;
- (b) That of *time*, represented by the symbol T ;
- (c) That of *mass*, represented by the symbol M .

In constructing the metric system an attempt was made to make the unit of mass a derived one by defining it as the mass of a cubic decimetre of water at maximum density. But it would be objectionable to use as absolute a unit which depends on the result of an experiment, because its value would never be definitive, and would require constant correction as more exact determinations are made. Hence the practical kilogram is simply a certain mass of metal, which the founders of the metric system made as near as possible to that of a cubic decimetre of water.

In recent times a system of units in which, for

Length, $L = 1$ centimetre,
Time, $T = 1$ second,
Mass, $M = 1$ gramme,

has come into extensive use, and is known as the C. G. S. system, from the initial letters of the three units. Some of these units have received special names, which we shall give in connection with the definitions, but others have not.

The derived units of the more common physical quantities are defined as follows:—

The unit of *velocity* is that velocity which, if uniform, will carry a body over unit length in unit time (C. G. S., 1 centimetre per second).

The unit of *acceleration* (of velocity) is that acceleration which will increase the velocity by a unit in unit of time.

The unit of *force* is that force which, acting on a body of unit mass, free to move, will impress upon it unit velocity in unit of time (called the *dyne* in the C. G. S. system).

The unit of *surface* or *area* is a square whose sides are of unit length (C. G. S., a square centimetre).

The unit of *volume* is a cube whose edges are each of unit length (C. G. S., a cubic centimetre).

The unit of *work* is the work done by unit of force acting on a body in the direction of its motion as it moves through unit length (C. G. S., the *erg*).

The unit of *kinetic energy* is the energy of a mass of *two* units moving with unit velocity (when $m = 2$ and $v = 1$ we have $\frac{1}{2}mv^2 = 1$). This unit is, in the C. G. S. system, also called the *erg*.

The unit of *heat* is that amount of heat which will raise the temperature of unit mass of water 1°C . As the amount of heat necessary to produce this effect varies with the temperature of the water, there is a small range of uncertainty in this definition, on the best way of avoiding which there is, as yet, no general consensus among physicists. The theoretically best unit of heat would be that generated by the transformation of a unit of kinetic energy or of work into heat; for example, the heat generated by the friction of dragging a weight by a force of one unit through a unit of length. This unit would be an *erg*, but would not be of ready practical use. The most common practical unit of heat is the *calorie*, being the amount of heat required to raise the temperature of 1 kilo-

gram of water 1°C . In the C. G. S. system the mass of water supposed in the definition should be 1 gramme. The C. G. S. unit of heat is therefore $\frac{1}{1000}$ of a calorie, but it has not received any special name.

Electrical units. In *electricity* two systems of measuring quantities of electricity are used. In the electrostatic system the unit of electricity is that quantity which will repel an equal quantity at unit distance with unit force. In the electromagnetic system the measure depends on the magnetic effect produced by an electric current. The latter system best serves ordinary purposes, and is therefore generally used. It is adopted in the following statements and definitions, in which we begin with those relating to magnetism.

A magnetic pole of unit strength is that pole which repels an equal pole at unit distance with unit force.

The unit of intensity of a magnetic field is the intensity of that field in which a unit pole is acted on by unit force.

The electric current of unit strength is, in the C. G. S. system, that current which, moving along a circular arc of radius and length both unity, will produce at the centre of the circle a field of unit intensity. It follows that if a current of strength C moves around a coil of radius r , each turn of the coil will produce, at its centre, a field intensity of

$$\frac{2\pi C}{r}.$$

The unit of quantity of electricity is the quantity conveyed by unit current in unit time.

A conductor has unit capacity when a charge of unit electricity produces unit of potential on its surface.

The difference of potential between any two points is the work required to move unit quantity of electricity from one point to the other, the algebraic sign being so taken that positive electricity tends to move from points of greater to points of smaller potential. The potential produced by positive electricity is therefore positive, and that produced by an infinitesimal quantity dq of electricity at a distance r is algebraically expressed by dq/r . Its unit may therefore be defined as the potential produced by unit of electricity at unit distance.

The electromotive force between two adjacent points is the difference of potential between those points, and has therefore the same unit as potential.

A conducting wire has unit of resistance when, with unit difference of potential between its ends, a current of unit strength passes through it.

Ohm's law is that between the electromotive force E , the strength C of a current, and the resistance R of a conductor subsists the relation

$$E = CR.$$

Some of the preceding units are either too small or too large for convenient general use. Others are therefore introduced in practice, named and defined as follows:—

The practical unit of resistance called the *ohm* is theoretically defined as

$$\text{the C. G. S. unit} \times 10^9,$$

and practically defined as the resistance of a column of mercury of uniform cross section, of mass 14.4521 grams, and 1.063 millimetres in length, at temperature 0°C . The cross section of this column is one square millimetre.

The practical unit of electromotive force, called the *volt*, is

$$\text{the C. G. S. unit of potential} \times 10^8.$$

The practical unit of current, called the *ampère*, is

$$\text{the C. G. S. unit} \div 10.$$

The practical unit of quantity of electricity, called the *coulomb*, is

$$\text{the C. G. S. unit} \div 10.$$

The practical units of capacity, called the *farad* and the *microfarad*, are:—

$$\text{Farad} = \text{C. G. S. unit} \div 10^9,$$

$$\begin{aligned} \text{Microfarad} &= \text{C. G. S. unit} \div 10^{15}, \\ &= \text{Farad} \div 10^6. \end{aligned}$$

The practical unit of work, called the *joule*, is 10^7 ergs.

The practical unit of power, called the *watt*, is the power which does one joule of work per second.

The *horse-power* is about 746 watts.

The *kilowatt* is 1000 watts.

The C. G. S. electrical units to be used in the preceding definitions are electro-magnetic. They are equal to the corresponding electro-static units multiplied or divided by numbers approximately equal to 3×10^{10} , or its powers, as follows:—

Unit of Resistance,	$\div 3^2.10^{20}$,
„ Potential,	$\div 3.10^{10}$,
„ Current,	$\times 3.10^{10}$,
„ Quantity,	$\times 3.10^{10}$,
„ Capacity,	$\times 3^2.10^{20}$.

The number $3 \cdot 10^{10}$ is so near to the velocity of light in the C. G. S. system that it is supposed to be identical with it.

Literature: EVERETT, *Units and Physical Constants*. (S.N.)

Unit (social): see SOCIAL UNIT.

Unitarianism [Lat. *unus*, one]: Ger. *Unitarianismus*; Fr. *unitarianisme*; Ital. *unitarianismo*. (1) A term used by Sir William Hamilton alone (*Lects. on Met.*, i. 295) as equivalent to monism. One who denies dualism in favour of either mind or matter as the sole reality is a unitarian. (J.D.)

(2) The doctrine of a Christian sect which denies the Trinity and the divinity of Christ, thus emphasizing the oneness of God.

Unitarianism in this sense is widespread in England and the United States. (J.M.B.)

Unities (the dramatic): see UNITY AND PLURALITY, *passim*.

Unity (and **Plurality**) [Lat. *unitas*, oneness]: Ger. *Einheit* (and *Mehrheit*); Fr. *unité* (and *pluralité*); Ital. *unità* (and *pluralità*). Formally, unity means whatever exists, or is considered, as a single, indivisible reality, and by whose repetition composite beings, or through whose agency derived beings, exist. (J.D.)

(1) A universally accepted understanding as to the formation of Latin words would require *unity* to mean that which is essential to the number one.

If we consider the number one, irrespective of the possibility of two, three, &c., it involves no idea of number (and therefore not of totality or collection), nor even any idea of relation. The idea would, therefore, be found in a pure state only in an immediate consciousness which should make no distinction of any kind, whether between subject and object, or of the parts of the object. But the term is never used in this sense, unless with an accompanying explanation.

(2) The oneness element of experience which involves a positive assignment of the number one, and which must be originally one, and not a total.

Much may be said for the opinion that we are thus brought to the event of acting and being acted upon; for that must be *one*, and is the only element of experience whose essential peculiarity is entirely lost in any generalization of it. The negative oneness of immediate consciousness—as, for example, it appears in the idea of any particular colour—does not resist generalization, the idea of

redness in general having the same sort of unity as that of the scarlet of mercuric iodide or the colour of aniline red (magenta). But the moment I pass from the idea of a particular item of my experience, such as seeing a boat with a couple of men going over Niagara, to the slightest generalization of it, such as that of the *memory* of seeing the event, or the general conception of going over Niagara, the positive oneness entirely disappears.

Nevertheless, the word unity is seldom applied to this sort of oneness, which goes by the name of *individuality*. There is no individuality in a quality of immediate consciousness such as magenta or solferino, because there is no setting of object over against subject, which is requisite before oneness can be positively assigned to an idea (positive oneness thus involving duality); but neither is there any generality in the immediate consciousness, as long as it remains nothing more than what it first was. The purest oneness does not involve the least reference to plurality, and is therefore not positively opposed to generalization, and is not destroyed when generalization takes place. But positive and insistent oneness necessarily involves, or rather springs out of, the idea of duality, and distinctly denies it; so that generalization destroys it; it is the otherness of otherness, the negation of negation.

(3) The idea which the word unity is usually employed in philosophy to express is that of a general (in the most general sense) in its relation to particulars, which would be much more accurately called 'totality.'

Unity is thus used, not to express pure oneness, nor yet positive oneness, but to express the negation of multitude in the object to which it is attributed. Thus it involves a distinct reference to the possibility, not of duality merely, as positive unity does, but of *plurality* (in the sense of more than two). The first unity might be named *simplicity* or *firstness*; the second is very appropriately termed *individuality*; the third, which is nearly what Kant terms *synthetical unity*, ought to have some better designation than *totality* or *universality*.

Unity in certain old books (as in the *Institutiones Metaphysicae* of Burgersdicius, 1647) is divided into *singular* and *universal unity*, the former belonging to singulars, the latter to universals. Singular unity is either *material* (or *numerical*) or *formal*. *Material unity* is defined as that which belongs to the

singulars in so far as they are considered as units with individualizing differences; which is an awkward attempt to define individuality. *Formal unity* is 'the unity which belongs to singulars abstractedly from their individualizing differences.' These definitions depend upon a particular theory of individuation. *Universal unity* is distinguished from *communicability*, which is the reference to the plurality of singulars; and these two elements together make up *universality*. *Numerical unity* implies repugnance to multiplication; *formal unity*, indifference to multiplication; *universal unity*, non-repugnance to multiplication. The nature of the *fundamentum universalitatis* distinguishes the mediaeval realist from the nominalist. The nominalists generally do not admit that there is any similarity in things apart from the mind; but they may admit that this exists, provided they deny that it constitutes any unity among the things apart from the mind. They cannot admit the latter and remain consistent nominalists. Thus, a nominalist may admit that there is in the events themselves an agreement consisting in the uniformity with which all stones dropped from the hand fall to the ground; but if he admits that there is anything at all, except the mere fact that they happen to do so, that should in any sense *determine* the different stones to fall every time they are dropped, he ceases to be a good nominalist and becomes a mediaeval realist. *Unity* is further divided (by Burgersdicius, whom we continue to follow) into *unity of simplicity* and *unity of composition*. *Simplicity* is said to be unity devoid of all multitude; *composition* is the union of a plurality of things. This definition of simplicity is confessedly defective in representing this mode of unity as having a reference to multitude. *Composition* is divided into *real*, *rational*, and *modal*. *Real composition* is the union of distinct entities in the real thing itself. It is either *actual* or *potential*. *Actual composition* is either *per compositionem*, as when water and alcohol are mixed, or *per aggregationem* (as in an army). *Potential composition* is when one thing is united in *potentia* to another. It is either *per informationem* or *per inhaerentiam*; a distinction peculiar to a certain kind of Aristotelianism. *Rational composition* is either of things which differ by reason alone, or of things brought together in one concept; it includes, firstly, genera, species, &c.; secondly, equality, similitude, &c.; thirdly, agreement in effects, external

causes, &c. *Modal composition* is composition from a thing and a mode. Most of the above distinctions go back to Scotus, and a few are still earlier.

Unity is divided by Kant into *analytical* and *synthetical*. He never defines or explains these terms; but if we remember that, in his use of words, multiplicity of elements is essential to unity, it is easy to see that what he means by analytical unity is the unity of that which is given in its combined state and is analysed by ordinary reflection. Thus we perceive a fact; and in order to express or think it, we analyse it, and the relation of the percept to the elements resulting from this analysis is very inappropriately called *analytical unity*. But when in the formation of the percept different sense impressions are put together, so that ordinary thought cannot proceed from whole to parts, but an operation more or less subconscious is supposed to manufacture the whole out of the parts, the relation of the whole to the parts is called *synthetical unity*. Three kinds of transcendental synthesis are recognized in the first edition of the *Krit. d. reinen Vernunft*, each resulting in a *synthetical unity*: they are the synthesis of apprehension in the intuition, which produces one representation; the synthesis of reproduction in the imagination; and the synthesis of recognition in the concept, which gives the unity of the rule. The *transcendental unity of apperception* is the unity which belongs to all my cognitions arising from a correlative *unity* of consciousness. It is transcendental, objective, and original. Besides these modes of transcendental unity, Kant recognizes other kinds of synthetical unity, some of which are empirical and contingent. There are also different modes of rational unity, some speculative, others moral.

That which the Scholastics meant by *transcendental unity* was unity in the sense in which it is said *Quodlibet ens est unum*, that is, is self-consistent.

We must not forget the three *dramatic unities* of *time*, *place*, and *action*, requiring the events represented to be included in one day, in one scene, and all to relate to one plot. Unity of action is set forth by Aristotle (*Poetics*, chaps. viii, ix, xviii). Unity of time is mentioned by him. That is, the action of a tragedy should, when convenient, be compressed into one day (*Poetics*, chap. v). The unity of place was remarked by French critics to have been observed by the Greek tragedians.

A *unity* in mathematics is a quantity which multiplied by any other gives that other. There can thus be but one unity in an algebra, although there may be many units. (C.S.P.)

Aesthetic unity: singleness or congruousness of effect immediately produced through sensuous presentation.

Formal and material unity: scholastic terms, derived from Aristotle. Material unity is that which pertains to an individual as such, and which cannot be abstracted even in thought from the individual; the material unity of Socrates is just that which constitutes him Socrates. Formal unity is that which pertains to an individual in such a way as to be distinguishable from his individuality; the humanity of Socrates can be conceived apart from Socrates, and as such constitutes a formal unity. Cf. *IDENTITY* (formal, and material).

Functional unity: a unity which consists not in the composition of elements or parts of structure as such, but in the conspiring or working together of these various parts—a unity of value effected—also termed teleological unity. The term ideal unity properly has the same meaning.

Logical unity: that which is constituted by the mutual support given to one another by the various terms and propositions of reasoning in the process of establishing a conclusion.

Metaphysical unity: that whose identity is inherent, having within itself a principle of being or action which makes it essentially distinct from all other beings.

Moral unity: that which is produced by a variety of factors co-operating intentionally, and under the control of some consciously regulating principle, to bring about a particular result; in this sense the state, as well as the person, may be a moral unity.

Numerical unity: that the identity of which is external, rather than intrinsic; whatever is sufficiently marked off or separate from other things to be counted as one; also termed physical or mechanical unity. Cf. *NUMBER* (different topics).

Organic unity: a unity which is constituted in and through diversity, since it requires a manifold of parts or members which are mutually dependent upon one another; opposed to a mechanical unity or unity of an aggregate in which every part is so homogeneous with the other parts and with the whole as to be capable of being itself a unity,

which in quality (though not in quantity) is regarded as the same as the original unit. Cf. *ORGANISM*.

The Kantian philosophy also supplies a number of technical distinctions (see *KANTIAN TERMINOLOGY*,—especially the synthetic or transcendental unity of apperception—and above).

We owe most of the main distinctions to Aristotle, who differentiated absolute and relative unity; the former being continuous and indivisible within itself, the latter complex and diversified, as of an orchestra. Unity proper he subdivided into four forms: first, that of continuity, not due to contact; second, natural unity of form and figure—that is, original, not due to violence or external force; third, individual, that which is numerically distinct; fourth, unity of the universal, that constituted by thought as present in a variety of objects—practically equivalent to the formal unity of the Scholastics.

But the philosophic interest of the idea of unity cannot be gathered from any cluster of formal definitions or distinctions. It attaches to the content of the idea. All philosophy is a search for unity, or, if this cannot be found, for unities; and it is the nature and quality ascribed to unity or unities, together with the reasons given for selecting it as such, that constitute the true philosophic history of the term. See *MONISM*, *MONADS*, *PLURALISM*, *ONE AND MANY*.

Moreover, *unum* was with the Scholastics one of the three ultimate predicates of being, and it was an axiom of philosophy that every real being is unity, and every true (not artificial) unity is being. Hence the standard and definition of unity and substance are the same. See *SUBSTANCE*, and *TRANSCENDENT*. The whole question of the philosophic ground of mathematics (on the side of arithmetic and algebra) is connected with the question of unity. (J.D.)

Unity in Variety: Ger. *Einheit in der Mannigfaltigkeit*; Fr. *unité dans la variété*; Ital. *unità nella varietà*. An agreement in certain respects of several objects or parts of one object, which differ in other respects, thus capable of being grasped as a whole, while at the same time they are distinguished.

This is the objective correlate of the law of all intelligence which is a synthetic process of discrimination and identification or relation. The unity may be that of a spatial or temporal whole, that of identity of quality, that of conformity to some idea or law, or

that of co-operation to a single end. It relates to both form and content of the aesthetic object. While absolute unity becomes emptiness or monotony, and absolute variety would be chaos, the varying degrees in which unity or variety is prominent give rise to a range of aesthetic values. In addition to the formal element of adjustment or adaptation, and the connected free play of mental powers in apprehending objects where unity in variety is conspicuous, there seems to be involved to some extent in 'unity' the value attaching to the maintenance and recognition of one's own identity, while variety tends to enlargement and freedom.

The principle was enunciated by Plato and Aristotle in reference to literary composition, and has been given recognition as at least an important condition of formal beauty by nearly all aestheticians.

Literature: see titles under AESTHETICS, ART, and BEAUTY; see especially FECHNER, *Vorschule d. Aesth.* (1876), chap. vi; KÖSTLIN, *Aesthetik* (1869); DONKIN, *Mind*, 1897, 511 ff. (J.H.T.)

Unity of God (in theology): Ger. *Gottes-einheit*; Fr. *unité de Dieu*; Ital. *unità di Dio*. The doctrine that in the last analysis God is one and not many, and that the distinctions in the divine nature presuppose its substantial oneness.

Unity is the principle of monotheism. The Christian doctrine of tripersonality made it necessary to emphasize the unitary side of the divine nature. Unity may be asserted in such a way as to be inconsistent with personal distinctions. This gives abstract monotheism. Judaism rests on the monotheistic conception of Jahveh or Jehovah, which is consistent with internal distinction if not with a plurality of persons.

Literature: see MONOTHEISM, JEHOVAH, TRINITARIANISM, and UNITARIANISM. (A.T.O.)

Universal (and **Universality**) [Lat. *universalis*, pertaining to all]: Ger. *allgemein*; Fr. *universel*; Ital. *universale*. (1) This word was used in the middle ages where we should now use the word GENERAL (q. v.). Another synonym was *praedicabile*: 'Praedicabile est quod aptum natum est praedicari de pluribus,' says Petrus Hispanus. Albertus Magnus says, 'Universale est quod cum sit in uno aptum natum est esse in pluribus.' Burgersdicius, literally translating from Aristotle, says, 'Universale (τὸ καθ' ὅλον) appello, quod de pluribus suapte natura praedicari aptum est,' i. e. ὁ ἐπὶ πλείονων πέφυκε κατηγορεῖσθαι. When the

Scholastics talk of universals, they merely mean general terms (which are said to be *simple universals*), with the exception here following.

(2) The five terms of second intention, or more accurately the five classes of predicates, *genus, species, difference, property, accident*, were in the middle ages (as they still are) called 'the predicables.' But since predicable also means fit to be a predicate, in which sense it is almost an exact synonym of universal in the first sense, the five predicables came to be often referred to as 'the universals.'

(3) Predicated, or asserted, in a proposition *de omni*; said to be true, without exception, whatever there may be of which the subject term is predicable. See QUANTITY (in logic).

Thus 'any phoenix rises from its ashes' is a universal proposition. This is called the *complex* sense of universal. The subject must be taken in the distributive sense and not in the collective sense. Thus, 'All man is all redeemed,' which is Hamilton's 'toti-total proposition,' is not a universal proposition, or assertion *de omni*, in the sense defined by Aristotle in the *dictum de omni*; for it means that the collection of men is identical with the collection of the redeemed, and not that each man without exception is all redeemed. Leibnitz rightly insists that a universal proposition does not assert, or imply, the existence of its subject. The first reason for this is that it accords with the definition; that is, the *dictum de omni*, which is that that is asserted universally of a subject which is said to be predicable of whatever that subject may be predicable. For this may be done without asserting that the subject is predicable of anything in the universe. The second reason is that the term *universal proposition* is a term of formal logic. Now the principal, or at least the most essential, business of formal logic is so to formulate direct syllogism as not to represent it as requiring more or less than it really does. Now the major premise of a direct syllogism must be universal, but need not imply the existence of anything of which the subject should be predicable. Hence a form of universal proposition not asserting the existence of the subject is indispensable. Now that no second kind of universal proposition is needed will presently appear. The third reason is that it is necessary that formal logic should be provided with a form of proposition precisely denying every proposition coming

under each of its simple forms. Now, if a universal proposition asserting the existence of its subject is regarded as a simple form of proposition—as, for example, ‘There are inhabitants of Mars and every one of them without exception has red hair’—its precise denial would be a particular proposition not asserting the existence of the subject, which would be a most singular form, hardly ever wanted, and manifestly complex, such as, ‘Either there is no inhabitant of Mars, or if there be, there is one at least who has not red hair.’ It is obviously far better to make the simple particular proposition assert the existence of its subject, ‘There is an inhabitant of Mars who has red hair,’ when the universal form will not make the same assertion, or imply it: ‘Whatever inhabitant of Mars there may be must, without exception, have red hair.’ If every particular proposition asserts the existence of its subject, then an affirmative particular proposition *implies* the existence of its predicate also. It would be a contradiction in terms to say that a proposition *asserted* the existence of its predicate, since that of which a proposition *asserts* anything is its subject, not its predicate. But perhaps it is not quite accurate to say that the particular proposition *asserts* the existence of its subject. At any rate, this must not be understood as if, in such assertion, *existence* were a predicate not implied in a proposition which does not make this assertion (see Kant, *Krit. d. reinen Vernunft*, 1st ed., 599).

Every proposition refers to some index: universal propositions to the universe, through the environment common to speaker and auditor, which is an index of what the speaker is talking about. But the particular proposition asserts that, with sufficient means, in that universe would be found an object to which the subject term would be applicable, and to which further examination would prove that the image called up by the predicate was also applicable. That having been ascertained, it is an *immediate inference*, though not exactly *asserted* in the proposition, that there is some *indicable object* (that is, something *existent*) to which the predicate itself applies; so that the predicate also may be considered as referring to an index. Of course, it is perfectly legitimate, and in some aspects preferable, to formulate the particular proposition thus: ‘Something is, at once, an inhabitant of Mars and is red haired,’ and the universal proposition thus: ‘Everything that exists in

the universe is, if an inhabitant of Mars, then also red haired.’ In this case, the universal proposition *asserts* nothing about existence; since it must already be well understood between speaker and auditor that the universe is *there*. The particular proposition in the new form asserts the existence of a vague something to which it pronounces ‘inhabitant of Mars’ and ‘red haired’ to be applicable. See the remarks on ‘existence’ under PROPOSITION.

The universal proposition must be understood as strictly excluding any single exception. It is thus distinguished from the proposition ‘The ratio of the number of *A*’s to that of the *A*’s that are *B* is as 1 : 1,’ not merely in being distributive in form instead of collective, but also in asserting much more. Thus the ratio of the multitude of all real numbers to those of them that are incommensurable is as 1 : 1; yet that does not prevent the commensurable numbers from existing, nor from being infinite in multitude. Were it proved that the ratio of frequency of all events to such of them as were due to natural causation was 1 : 1, that would be no argument whatever against the existence of miracles; although it might (or might not, according to circumstances) be an argument against explaining any given event as miraculous, if such a hypothesis can be called an explanation. Now induction may conclude that the ratio of frequency of a specific to a generic event is 1 : 1, in the same approximate sense in which all inductive conclusions are to be accepted. Indeed, the ratios 1 : 1 and 0 : 1 may be inductively concluded with stronger confidence in their accuracy than any other ratio can be so concluded. But under no circumstances whatsoever can induction establish the accuracy or approximate accuracy of a strictly universal proposition, or that any given series of phenomenal events is, properly speaking, general (and therefore represents a possibly infinite class), or is even approximately general. Such propositions, outside of mathematics (taking this word so as to include all definitions and deductions from them), must either be entirely unwarranted, or must derive their warrant from some other source than observation and experiment. It might conceivably be established by testimony, as, for example, by a promise by a possibly immortal being to act in a certain way upon every occasion of a certain description; and thus it would not need to be an *a priori* judgment. (C.S.P.)

(4) The logical use (3) passes easily into the metaphysical. Provided the common attribute is regarded as important or essential, provided it is regarded as constituting a 'natural' genus or class, it expresses the *essence* of the thing under consideration—its permanent and abiding reality as distinct from transitory accidents. But since this essence is also what is *common* to a number of individuals, the class itself taken as an objective whole is regarded as a universal. When a predicate of this sort is applied to a subject, it expresses not merely an empirical, but a necessary, application to the whole of the subject-matter; the relationship ceases to be simply a quantitative one, and becomes qualitative or essential; e.g. 'All swans are white' would be a quantitative universal judgment, and so empirical. But 'all events must have a cause' is a qualitative universal—it is the 'essence' of an event to be caused. Now mediaeval thought was thus led to identify the universalia or generic notions with essences and with classes. Thus arose the discussion regarding the relation of universals to individual things (see *REALISM*, 1). Cf. *ABSTRACT IDEAS*.

(5) Aristotle had illustrated the common as the basis of a 'natural' class, by the common strain in various members of a family—those of common descent. This aspect of the term tends to identify the universal not merely with the static qualities or essence, but with the productive force—the generic is the generative—by which numerically distinct individuals are really connected with one another. This meaning presents a picture of what is meant by the objective reality of a universal. With modern science and the growth of the conception of force, causation, and the tendency to define (as in geometry) by reference to mode of production, this dynamic sense got the upper hand of the static. It is used in this sense in the school of Hegel to mean the general which, as function or activity, exists only in the specific differences to which it determines itself. (J.D.)

(6) Kant, in sundry places (as in *Logik* by Jäsche, § 21), draws a rather insignificant distinction between 'generale' or 'gemeine' Sätze and 'universale' or 'allgemeine' Sätze. The former are what are ordinarily called universal propositions. The latter are something more, apparently relating to any object whatsoever.

(7) Descartes, Leibnitz, Kant, and others appeal to the universality of certain truths

as proving that they are not derived from observation, either directly or by legitimate probable inference. There is only one such passage in Descartes; and even Leibnitz, though he frequently alleges the *necessity* of certain truths (that is, their being propositions of necessary mode) against Locke's opinion, yet in only one place (the 'Avant-Propos' of the *Nouveaux Essais*) distinctly adds the criterion of universality. Descartes, Leibnitz, and Kant more or less explicitly state that that which they say cannot be derived from observation, or legitimate probable inference from observation, is a universal proposition in sense (3), that is, an assertion concerning every member of a general class without exception. Descartes (*Letter xcix*) argues that no legitimate inference can be made from external phenomena to the proposition that 'Things equal to the same are equal to each other,' since that would be to infer a 'universal' from a 'particular.' Leibnitz uses almost the same language: 'D'où il nait une autre question, savoir, si toutes les vérités dépendent de l'expérience, c'est-à-dire de l'induction et des exemples, ou s'il y a un autre fondement. . . Or, tous les exemples qui confirment une vérité générale, de quelque nombre qu'ils soient, ne suffisent pas pour établir la nécessité universelle de cette même vérité: car il ne suit pas que ce qui est arrivé arrivera toujours de même.' Kant expresses himself still more unmistakably (*Krit. d. reinen Vernunft*, 2nd ed., Einleitung, ii): 'Erfahrung giebt niemals ihren Urtheilen wahre und strenge, sondern nur angenommene und comparative Allgemeinheit (durch Induction), so dass es eigentlich heissen muss: so viel wir bisher wahrgenommen haben, findet sich von dieser oder jener Regel keine Ausnahme. Wird also ein Urtheil in strenger Allgemeinheit gedacht, d. i. so, dass gar keine Ausnahme als möglich verstattet wird, so ist es nicht von der Erfahrung abgeleitet, sondern schlechterdings *a priori* gültig. Die empirische Allgemeinheit ist also nur eine willkührliche Steigerung der Gültigkeit, von der, welche in den meisten Fällen, zu der, die in allen gilt, wie z. B. in dem Satze: alle Körper sind schwer; wo dagegen strenge Allgemeinheit zu einem Urtheile wesentlich gehört, da zeigt diese auf einem besonderen Erkenntnisquell derselben, nämlich ein Vermögen des Erkenntnisses *a priori*. Nothwendigkeit und strenge Allgemeinheit sind also sichere Kennzeichen einer Erkenntnis *a priori*, und gehören auch unzertrennlich zu einander.' But notwithstanding

ing the fact that the whole logic of all these writers, especially Kant, requires the word universal to be understood in that sense, yet there are, in the works of all of them, some passages which lend a certain colour of excuse to the stupid blunder of some interpreters who teach that by necessity they mean the irresistible psychical force with which the proposition demands our assent, and that by universality they mean catholicity, i.e. the catholic acceptance of it *semper, ubique, et ab omnibus*. Descartes in particular, and Leibnitz in some measure, perhaps even Kant (though it would be very illogical for him to do so), did more or less attach weight to the irresistible apparent evidence, and to some degree to the catholic acceptance, of propositions as tending to persuade us of their truth; but not as criteria of their origin. It is, however, to be noticed that false interpreters of Kant have used the word universal in the sense of being accepted by all men—the sense of *κοινός* in the phrase *κοινὰ ἔννοια*.

The words universal and universality enter into various technical phrases:—

Aesthetic universality: a term of Kant for a universality not formally stated but illustrated by examples.

Complex universality: see above.

Natural universal: a natural sign predicable of a plurality of things, as smoke is a sign of fire. The nominalistic doctrine is that nothing out of the mind is universal in that sense. See Ockham, *Logica*, I. xiv. *ad fin.*

Objective universality: the universality of a concept or rule; a Kantian phrase.

Posterioristic dictum de omni and *Posterioristic universal*: universal predication as defined by Aristotle in the fourth chapter of the first book of the *Posterior Analytics*, where it is defined as the negative of the particular: *Κατὰ παντὸς μὲν οὖν τοῦτο λέγω ὃ ἂν ᾖ μὴ ἐπὶ τινὸς μὲν τινὸς δὲ μὴ μηδὲ ποτὲ μὲν ποτὲ δὲ μὴ*—‘I call that universally predicated (*de omni*) which is not in something, in something not, nor now is, now is not.’

Prioristic dictum de omni and *Prioristic universal*: universal predication as defined by Aristotle at the end of the first chapter of the first book of the *Prior Analytics*: *λέγομεν τὸ κατὰ παντὸς κατηγορεῖσθαι ὅταν μηδὲν ᾖ λαβεῖν τῶν τοῦ ὑποκειμένου καθ’ οὗ θάτερον οὐ λεχθήσεται*—‘We say that anything, *P*, is predicated universally (*dictum de omni*) when nothing can be subsumed under the subject of which *P* is not intended to be predicated.’

Simple universality: the generality of a general term. See (1) above.

Universal cause: a cause which with one and the same efficiency concurs with others in producing different effects. The idea is that ‘particular causes,’ that is, finite beings, generate only their own kind. But God and heaven produce all sorts of results natural and moral in one and the same manner.

Universal consent: catholicity (see above).

Universal conversion: the conversion of a proposition into a universal proposition. See Hamilton, *Lect. on Logic*, Appendix V, iii. footnote 14.

Universal grammar: grammar so far as it applies to every possible language. The ordinary doctrine of the middle ages was that in its main features, and even in great detail, one grammar was common to all languages. See Thurot, in *Notices et Extraits*, xxii. 125 ff.

Universal logic: the unusual division of logic into a universal and a particular part is due to Avicenna, who makes the former to consist of the matter of the *Predicaments*, *Peri hermeneias*, and *Prior Analytics*, while the latter, treating of special kinds of reasoning, demonstrative, probable, and sophistical, embraces the matter of the *Posterior Analytics*, *Topics*, and *Sophistici Elenchi*. Kant uses precisely the same division in the introduction to the transcendental logic (*Krit. d. reinen Vernunft*, 1st ed., 53).

Universal moods of syllogism: those in which both premises and the conclusion are universal.

Universal parts and whole: the parts and whole of the logical breadth of a term, proposition, or argument.

Universal unity is that sort of unity which belongs to generalness. Burgersdicius (*Instit. Metaph.*, I. xiii. § 1) explains it in these words: ‘Unitas universalis est quae convenit rebus quatenus indivisae sunt in plures res eiusdem nominis et essentiae, et apta in eas dividatur. Universalitas enim haec duo postulat, unitatem sive indivisionem, et communitatem sive aptitudinem ad divisionem et multitudinem. Sic *animal*, ut est universale, in se *unum* est, una enim definitione potest explicari, et aptum est dividi in hominem et bestiam.’

Universal validity: according to some logicians is the validity of such reasonings as are ‘calculated to operate conviction on all reasonable minds’ (Hamilton, *Lect. on Logic*, xxvi). If he had omitted the word reason-

able, and said 'calculated to work conviction on all minds,' this would not have proved they had any validity at all; for the validity of a reasoning depends upon whether it really will lead to the truth, and not upon whether it be believed that it will. Thus the word reasonable is the only pertinent word in the definition. But in fact there is no division of logical validity into universal and particular.

Universal ante rem: Albertus Magnus, in his commentary on the *Organum*, which is valuable on account of being largely drawn from Algazeli, Alfarabius, and Avicenna (*Liber de Praedicabilibus*, chapter beginning, 'Quamvis autem haec determinata sint supra vires logicae'), says after an explanation too long to quote: 'Et hoc est quod dixerunt antiqui, triplices esse formas, *ante rem*, scilicet, quae sunt formae secundum se acceptae principia rerum existentes, et *in re*, sive cum re ipsa, quae sunt formae existentes in ipsis dantes eis nomen et rationem per id quod sunt aptae esse in multis et universales (non tamen secundum quod sunt in illis; secundum enim quod sunt in illis particularizatae et individuitatae et ad singularitatem ductae sunt). Sunt etiam formae *post rem* quae sunt formae per abstractionem intellectus ab individuantibus separatae, et in quibus intellectus agit universalitatem. Et primae quidem substantialia rerum principia sunt. Secundae autem rerum substantiae. Tertiae autem accidentia et qualitates, quae notae rerum in anima acceptae vocantur et dispositiones vel habitus.' There is much more. They are also called *ante multa*, *in multis*, and *post multa*.

Universal in causando: same as *Universal cause* (above).

Universals in essendo: according to the Conimbricenses are common natures existing in many inferiors. Burgersdicius and others identify them with universals *ante rem*, otherwise called the metaphysical universals, or Platonic ideas.

Universals in praedicando, otherwise called *logical universals*: the universals concerning which the principal dispute between the sects in the 12th century took place. Tataretus, whose tendencies are Scotistic, says: 'Universale in praedicando potest capi dupliciter, uno modo prime-intentionaliter, alio modo secunde-intentionaliter seu pro per se significato. Unde universale prime-intentionaliter captum non est aliud quam aliquid cognitum ut unum in multis et de multis cui ex natura rei non repugnat sic esse, cuius

modi sunt significata adaequata terminorum communium. Sed universale secunde-intentionaliter captum non est aliud quam quidam respectus rationis causatus per actum comparativum intellectus comparantis aliquid in ordine ad sua inferiora, ut unum in multis et de multis.'

Universal in significando: a sign which signifies a number of things. The Conimbricenses instance a comet, which presages that many persons are to be seized with maladies, also general words, whether spoken, written, or thought.

Universal per voluntariam institutionem: a term of Ockham's, opposed to natural universal. A conventional sign having a general signification.

Universal simpliciter and *secundum quid*: a proposition is said to be *universal simpliciter* which asserts itself of any individual object of the subject term; that is, an ordinary universal proposition. A proposition is *universal secundum quid* if it is asserted not of every object individually, but of some *representative* (in some definite sense) of each individual, as *Omnia animalia fuerunt in arca Noachi*. (C.S.P., C.L.F.)

Universal Consent or Catholicity (in philosophy): see UNIVERSAL, and TESTS OF TRUTH.

Universal Happiness: Ger. *allgemeine Glückseligkeit*; Fr. *félicité universelle*; Ital. *felicità universale*. The 'happiness of the greatest number.' See HAPPINESS, GREATEST HAPPINESS, and ETHICAL THEORIES (Hedonism). (J.M.B.)

Universal Postulate: no foreign equivalents in use. The term is used as a technical one by Spencer, to denote the 'inconceivableness of the negative' of any proposition as the supreme test of the necessary coexistence of a given subject and predicate. It has psychological necessity—the necessity of thinking the proposition in such and such a way; and also logical—the reason for holding it valid. This criterion is in effect nothing but the criterion of RATIONALISM (q. v.) as stated by Leibnitz—the impossibility of the opposite. As such, it was shown by Kant to be applicable only to 'analytic judgments.' Cf. TESTS OF TRUTH. (J.D.)

Universalism: Ger. *Lehre der Universalisten*; Fr. *universalisme*; Ital. *universalismo*. The doctrine of the final salvation of all men, founded by its advocates on the following postulates. (1) God's essential goodness and love; (2) the unlimited scope of Christ's redemption;

- (3) the extension of probation beyond death;
 (4) the perfectibility of human nature.

Universalism was held by some of the early Church Fathers, and found advocates among the reformed thinkers in Germany, France, and England. Its great American apostle was John Murray, who crossed from England in 1770. The creed took institutional form for the first time on American soil, being organized into a church in 1803 at Winchester, New Hampshire, by the adoption of a confession and the acquisition of legal status. It is at present a large and flourishing sect.

Literature: The Universalist Register, Boston; HOSEA BIGLOW, *The Ancient Hist. of Universalism*; TRAYER, *Theol. of Universalism* (1873); DODGE, *The Purpose of God* (1894); O. CONE, *Gospel Criticism and Historical Christianity* (1891). (A.T.O.)

Universalistic Hedonism: Ger. *universalistischer Hedonismus*; Fr. *hédonisme universaliste*; Ital. *edonismo universalista*. The doctrine that the moral end is 'the greatest happiness of the greatest number.' See ETHICAL THEORIES (Hedonism), and UTILITARIANISM. (J.M.B.)

Universality: Ger. *Allgemeingültigkeit*; Fr. *universalité*; Ital. *universalità*. See UNIVERSAL, and TESTS OF TRUTH; and cf. ABSTRACT IDEA.

Universe [Lat. *unus*, one, + *vertere*, to turn]: Ger. *Weltall*, *All*; Fr. *univers*; Ital. *universo*. The term is often used as synonymous with WORLD (q. v.), but is distinguished from it by the idea of completeness, all-inclusiveness.

So the German *Weltall* is distinguished from *Welt*. It, rather than world, is the equivalent of the Latin *MUNDUS* (q. v.). It is sometimes restricted to the entire created system, but is also used, like the Greek one-and-all (*én kai tò pân*), to include God as well. In this last sense it is equivalent to nature as used by Spinoza. It is also used in logic to denote the subject or topic taken as a whole—the UNIVERSE (q. v.) of discourse. (J.D.)

Universe (the) [Lat. *universum*, combined, from *unus*, one, + *vertere*, to turn]: Ger. *(das) Weltall*; Fr. *(l')univers*; Ital. *(l')universo*. (1) The collection of all material things, *tò pân*; the word *universum* occurs in this sense in Cicero.

'Par l'espace,' says Pascal (*Pensées*, i. 6), 'l'univers me comprend et m'engloutit comme un point. Par la pensée, je le comprends.' It is used by some writers to include the spiritual world; by others to include God.

(2) *Universe* (in logic) of discourse, of a proposition, &c. In every proposition the circumstances of its enunciation show that it refers to some collection of individuals or of possibilities, which cannot be adequately described, but can only be indicated as something familiar to both speaker and auditor. At one time it may be the physical universe of sense (1), at another it may be the imaginary 'world' of some play or novel, at another a range of possibilities.

The term was introduced by De Morgan in 1846 (*Cambr. Philos. Trans.*, viii. 380), but De Morgan never showed that he fully comprehended it. It does not seem to be absolutely necessary in all cases that there should be an index proper outside the symbolic terms of the proposition to show what it is that is referred to; but in general there is such an index in the environment common to speaker and auditor. This De Morgan has not remarked; but what he has remarked has likewise its importance, namely, that for the purposes of logic it makes no difference whether the universe be wide or narrow. The idea of a limited logical universe was adopted by Boole and has been employed by all subsequent exact logicians. There is besides a universe of marks or characters, whenever marks are considered substantively, that is, as abstractions, as they commonly are in ordinary speech, even though the forms of language do not show it. Thus only, there comes to be a material difference between an affirmative and a negative proposition; and a meaning can thus alone be attached to Kant's limitative form of proposition. For it will then alone be one thing to say that an object wants some character common to all men, and another to say that it possesses every character common to all non-men. Only instead of this giving three qualities it gives four, for the assertion may be that an object wants some character common to all non-men; a point made by ancient writers.

In 1882 O. C. Mitchell extended the theory of the logical universe by the introduction of the idea of 'dimension' (see LOGIC, exact, ad fin.). (C.S.P., C.L.F.)

Unknowable (the) [Lat. *in + gnosceret*, to know]: Ger. *das Unerkennbare*; Fr. *l'inconnaissable, ce qu'on ne peut connaître*; Ital. *l'inconoscibile*. That which is not and cannot be known; that whose nature is such as to transcend or defy apprehension by any of the processes by which mind apprehends its objects. (J.D.—J.M.B.)

Of cognate terms 'inconceivable' is narrower, being rather equivalent to UNTHINKABLE (q. v.); that is, not to be apprehended by the cognitive or the conceptual processes. 'Incomprehensible' is still narrower, i. e. not to be apprehended mediately or by the discursive processes. (J.M.B.)

The existence of something unknowable is postulated from two different standpoints, one of which (roughly speaking) is that of ancient, the other that of modern thought. In the ancient view it is the essential nature and dignity of being which renders it unknowable; mind and knowledge are derivatives from the absolute reality which accordingly remains ineffably above them. Indeed, this absolute reality is the source of being which it also transcends. It is above distinctions of being and non-being as well as of knowledge and ignorance. This is the attitude of the Neo-Platonists. In modern thought the assumption of the existence of the unknowable is a consequence of the limitations of the faculty of knowledge. Kant, with his thing-in-itself contrasted with the phenomenon; Spencer, with his absolute contrasted with the related; and v. Hartmann, with his identification of the absolute with the unconscious, are the typical representatives of modern conceptions of the unknowable. Such theories differ from those of the agnostics and positivists in that the assertion of the absolute reality as unknowable is an integral part of the system, while in agnosticism and positivism it is a matter of pure indifference whether there be such hyper-phenomenal existences or not. They differ from phenomenalism in that the latter positively deny any such unknowable entity behind the knowable congeries of facts and series of events. (J.D.)

Unproductive Consumption: Ger. *unproduktive Consumption*; Fr. *consommation improductive*; Ital. *consumo non produttivo*. A cost which is not adequately compensated by the RETURN (q. v.).

This definition may be applied either from the private or from the public standpoint; but the latter method is much more common and more useful. If a man spends his income for NECESSARIES (q. v.), as defined in this work, his consumption is productive; i. e. the efficiency outweighs the waste. If he spends it for luxuries (see LUXURY), the case is reversed.

Many of the English economists attempted to confine the term productive to the produc-

tion of material objects; but this limitation is now regarded as impracticable.

The distinction between productive and unproductive consumption is more important than the distinction between productive and unproductive labour, because the amount consumed furnishes a standard of comparison to determine whether the production is or is not adequate. (A.T.H.)

Unpsychological Ethics: see IDEOPSYCHOLOGICAL ETHICS.

Unreal [*un* + REAL (q. v.)]: Ger. *unwirklich*; Fr. *sans réalité, irréel*; Ital. *irreale*. Lacking in those marks which to our apprehension or thought constitute REALITY (q. v.). Cf. REAL AND REALITY.

If the possession of such marks constitutes the reality of an object, their lack constitutes its unreality. It is sometimes held, however, that unreality has its own positive marks and is not merely the absence of reality. (J.M.B., G.F.S.)

Unreality: see UNREAL.

Unreality Feeling: see REALITY FEELING.

Unstable Equilibrium (in economics): Ger. *unbeständiges Gleichgewicht*; Fr. *équilibre instable*; Ital. *equilibrio instabile*. A balance of economic motives of such a character that any disturbance of the equilibrium, instead of producing a reaction that tends to drive matters back to the old adjustment, may tend to perpetuate and intensify itself.

The price of an article represents a stable equilibrium when a fall in price forms a motive for contracting the supply. If the conditions of production are such that the competitors must continue to produce at prices much lower than the old point of adjustment (OVERPRODUCTION, q. v.), the price equilibrium is an unstable one, and the value of the commodity is subject to violent fluctuations. (A.T.H.)

Unthinkable (the) [for derivation see THOUGHT]: Ger. (*das*) *Undenkbare*; Fr. (*l'*) *inconcevable, (l')* *impensable*; Ital. (*l'*) *impensabile*. As a technical term the word grows out of Sir William Hamilton's philosophy of the conditioned, especially as developed by Mansel, and borrowed by Herbert Spencer. According to his theory to think is to relate, or to condition. Hence anything which is absolute, or infinite, or unconditioned is, of necessity, unthinkable. It is inconceivable, and hence can be neither affirmed nor denied (Hamilton, *Discussions*, 13-6). (J.D.)

Unwritten Law: Ger. *ungeschriebenes*

Recht, Gemeinrecht; Fr. *droit non écrit*; Ital. *diritto consuetudinario*. (1) All law not made by or under legislative authority.

(2) In English and American law, the common law.

'In legislation both the contents of the rule are devised, and legal force is given to it, by simultaneous acts of the sovereign power, which produce "written law." All the other law sources produce what is called "unwritten law," to which the sovereign authority gives its whole legal force, but not its contents, which are derived from popular tendency, professional discussion, judicial ingenuity, or otherwise, as the case may be' (Holland, *Jurisprudence*, chap. v. 65). Law as formulated by judicial decision, although contained in the official law reports, is unwritten law; it is expository, and not in the nature of an original command by an authorized law-maker (Pollock, *Jurisprudence*, chap. i. 219).

The Roman law, differing from the English, classed as written law all that was received as law and contained in authentic written form, although it might not be derived from legislative authority (*Inst. of Just.*, i. 2, *De iure naturali, gentium, et civili*, 3, 9).

In France, before the Revolution, the Roman law was described as the *Droit écrit*, because it was originally the only form of written law there, and those provinces where it remained in force as common law were termed *pays de droit écrit* (Merlin, *Répertoire de Jurisprudence*, *Droit*).

Literature: BLACKSTONE, Commentaries, *Introd.*, § 3. (S.E.B.)

Upham, Thomas Cogswell. (1799-1872.) Educated at Dartmouth College and Andover Theological Seminary. Became assistant in Hebrew in the seminary, 1821; ordained as pastor of the Congregational Church at Rochester, N. H., 1823; professor of mental and moral philosophy in Bowdoin College, 1825.

Uprightness [Eng. *up + right*]: Ger. *Auf-richtigkeit, Rechtschaffenheit*; Fr. *droiture*; Ital. *dirittura*. The disposition which issues in the habitual practice of virtue; the ethical DISPOSITION (q. v.) as such.

It is opposed to goodness as an emotion which may be capricious, and to legality as observance which may not be ethical. (J.M.B.)

Use [Lat. *usus*]: Ger. (1) *Zweck*, (2) *Nutzen*, (3) *Gebrauch*; Fr. (1) *emploi*, (2) *utilité*, (3) *usage*; Ital. *uso*. (1) The end for which a thing is the appropriate means; as 'the use this is put to, or good for.'

(2) UTILITY (q. v., various topics).

(3) Actual employment or operation. Cf. USE AND DISUSE. (J.M.B.)

Use and Disuse: Ger. *Gebrauch und Nicht-Gebrauch*; Fr. *usage et désuétude* (Delage); Ital. *uso e disuso*. The actual employment or non-employment of a character or function more or less habitually in daily life.

Employed to indicate the part a function or character plays in the life and development of an individual creature and also as possibly affecting the next generation (cf. USE-INHERITANCE). (J.M.B., E.B.P.)

Use - inheritance: Ger. *Gebrauchsvererbung, Erbübung* (K.G.); Fr. *hérédité par l'usage* (Delage); Ital. *ereditarietà dall'uso*. Suggested by Ball for the Lamarckian theory (cf. LAMARCKISM) which holds that the effects of USE AND DISUSE (q. v.) of organs, or individually acquired MODIFICATIONS (q. v.) generally, are inherited. See Ball, *Are the Effects of Use and Disuse inherited?*

It is important to distinguish what is called 'definite' inheritance of particular effects, or true heredity, from the transmission of 'general effects' (on the distinction see Ewart, Pres. Address, *Nature*, Sept. 12, 1901). The latter all admit; but not the former. See ACQUIRED AND CONGENITAL CHARACTERS, and HEREDITY. Cope proposed (*Prim. Factors of Organic Evolution*, 192) the terms 'Genesisiology' for the science of heredity, 'Ctetology' for that of acquired characters, and 'Kinetogenesis' (development by motion) for use-inheritance; but none of them is in common use. (J.M.B., C.L.L.M.)

Usucaption: see PRESCRIPTION.

Usufruct [Lat. *usufructus*]: Ger. *Niessbrauch*; Fr. *usufruit*; Ital. *usufrutto*. A right during a certain time to the fruits of property belonging to another; a personal servitude, extending to the use and enjoyment of property for a certain term, without otherwise diminishing its substantial value.

A usufruct in land gave rights much like those of a tenant by lease in Anglo-American law.

'Usufructus est ius alienis rebus utendi, fruendi, salva rerum substantia' (*Dig.*, vii. 1, *De usufructu*, 1). Being a personal servitude, it died with the person, nor could he during his life transfer it to another.

It may be created by private grant, or by law as an incident of *status*, e.g. that of a parent (*Code Civil français*, Art. 384, 578 ff.). (S.E.B.)

Usury [Lat. *usura*, a charge for use]: Ger. *Wucher*; Fr. *usure*; Ital. *usura*. An exorbitant rate of interest.

In mediaeval times the name usury was applied to all payments for loans in excess of the return of the principal; while INTEREST (q. v.) was a phrase to justify certain specially excusable forms of usury. To-day, interest has become the general term, and the name usury is applied only to the specially unjustifiable cases of interest taking. (A.T.H.)

Uti possidetis (in international law) [Lat.]. The principle that the party in possession should be protected.

The term is generally used to describe a provision in a treaty, after a war, that conquered territory shall remain in the hands of the conqueror, either provisionally or permanently (see Calvo, *Le Droit international*, § 3150).

Uti possidetis ('as you possess') was the name given to one of the interdicts, or legal processes, of Roman law. It ran in favour of a possessor of land, to protect him against forcible dispossession by one claiming under an adverse title (*Dig.*, xliii. 17, *Uti possidetis*). (S.E.B.)

Utilitarianism: Ger. *Utilitarismus*; Fr. *utilitarisme*; Ital. *utilitarismo*. The ethical theory which regards adaptation to an end as the criterion of moral worth, the end being interpreted as the general happiness. Those who uphold this theory are called utilitarians.

'By the principle of utility,' says Bentham, 'is meant that principle which approves or disapproves of every action whatsoever, according to the tendency which it appears to have to augment or diminish the happiness of the party whose interest is in question.' 'To this denomination has of late been added or substituted the greatest happiness or greatest felicity principle.' 'The word utility does not so clearly point to the ideas of pleasure and pain as the words happiness and felicity do; nor does it lead us to the consideration of the number of the interests affected. . . . This want of a sufficiently manifest connection between the ideas of happiness and pleasure on the one hand and the idea of utility on the other, I have every now and then found operating, and with but too much efficiency, as a bar to the acceptance that might otherwise have been given to this principle' (*Princ. of Mor. and Legisl.*, chap. i). Mill says he 'has reason for believing himself to be the first person who brought the word utilitarian into use. He did not invent it, but

adopted it from a passing expression in Mr. Galt's *Annals of the Parish*.' The term is suggested by Bentham in a letter to Dumont, June 28, 1802 (see *Works*, x. 390). 'The creed which accepts as the foundation of morals utility, or the greatest happiness principle, holds that actions are right in proportion as they tend to promote happiness, wrong as they tend to produce the reverse of happiness' (Mill, *Utilitarianism*, chap. ii). Sidgwick restricts the term utilitarianism to 'Universalistic Hedonism, as taught by Bentham and his successors,' and as distinguished from the Egoistic Hedonism or 'Egoism' of earlier thinkers. 'I have made as marked a separation as possible between Epicureanism or Egoistic Hedonism, and the Universalistic or Benthamite Hedonism, to which I propose to restrict the term Utilitarianism' (*Meth. of Eth.*, 5th ed., 83 f.). 'By Utilitarianism is here meant the ethical theory that the conduct which, under any given circumstances, is objectively right, is that which will produce the greatest amount of happiness on the whole; that is, taking into account all whose happiness is affected by the conduct' (*Meth. of Eth.*, 411, 5th ed.). Cf. ETHICAL THEORIES (with literature). [Sidgwick called himself a 'modified utilitarian.' The school of English utilitarians—Bentham, James Mill, John Stuart Mill—has found its special historian and expositor in Leslie Stephen, *The English Utilitarians* (1900).—J.M.B.] (J.S.)

Utilitarians: Ger. *Utilitarier*; Fr. *utilitaires*; Ital. *utilitaristi*. Upholders of the theory of UTILITARIANISM (q. v.).

Utility (in aesthetics): Ger. *Nützlichkeit*; Fr. *utilité*; Ital. *utilità*. Value belonging to an object because it subserves some external end, as opposed to intrinsic or immediate value.

As an aesthetic principle it is used to explain aesthetic value (beauty) by showing that the beautiful object serves some desirable end (as a column to support a burden), and that its aesthetic value is due to this, wholly or in part. It has been admitted as aesthetic principle chiefly in architecture and the lesser arts—the 'dependent arts.'

Utility has been recognized as contributing to aesthetic value by Socrates, Plato, Home, Fechner, Guyau, and in special relation to natural selection in forming types by Hartmann and Santayana. It was rejected by Kant. See FITNESS (in aesthetics).

Literature: KANT, Critique of Judgment, §§ 2 ff.; FECHNER, Aesthetik (1876), chap.

xv; SANTAYANA, *Sense of Beauty* (1896), 155 ff.; HARTMANN, *Asthetik*, ii (Ausz. Werke, 4), 133-86, 594 ff., 599 ff.; BROWN, *Fine Arts* (1891), §§ 127 ff.; GUYAU, *Les Problèmes de l'Esthétique contemporaine* (4th ed., 1897), chap. ii. (J.H.T.)

Utility (in biology): value or advantage accruing to an organism from the possession of a character; the character is said to have utility, while the organism, by reason of the utility, is said to be 'fit' to survive. Cf. FIT-TEST (survival of), EXISTENCE (struggle for), and NATURAL SELECTION.

Cases in which an organism, organ, or function survives because of its fitness from the point of view of utility are covered by the term utility selection. NATURAL SELECTION, ORGANIC SELECTION, FUNCTIONAL SELECTION, GERMINAL SELECTION, SEXUAL SELECTION (see those terms) are all cases of utility selection. Degrees of utility, giving degrees of fitness to the organism, have given rise to the theory of SELECTION (q. v., in biology) value. (J.M.B., E.B.P.)

Utility (in economics). (1) The power of satisfying human desire.

(2) The measure of such power.

The old term, now obsolete, was 'value-in-use.'

It has been a long-established understanding that 'useful' in economics does not mean

'beneficial.' The most precise way of stating this, and one which implies more than appears upon its face, is, that the measure of utility is to be sought in intensity of motive, and not in quantity of happiness.

A clear understanding of the form in which utility measurement could be expressed was first attained by Jevons (see FINAL UTILITY). The writers of the Austrian school of political economy have carried this kind of analysis even further than Jevons. (A.T.H.)

Utility (in ethics): see UTILITARIANISM.

Utility Selection: see UTILITY (in biology), and SELECTION (in biology, ad fin.).

Utopia [Gr. οὐ, not, + τόπος, place]: Ger. *Utopie*; Fr. *Utopie*; Ital. *Utopia*. A place or state of complete perfection or happiness: an imaginary island described by Sir Thomas More in his romance *Utopia* (1516).

This island was perfectly governed and enjoyed perfect liberty and happiness. The term has come to be applied to any similar creations of the imagination, such as Plato's *Republic* and the modern pictures, by George (*Progress and Poverty*) and Bellamy (*Looking Backward*), of ideal social condition. The term carries an insinuation as indicating fanciful rather than logical thought, and thus as applying to the visionary and unpractical. Cf. SOCIALISM, passim. (J.M.B.)

V

VACHEROT — VACUUM

Vacherot, Étienne. (1809-97.) Born at Longres, France, he studied at Paris and became professor of philosophy at the Sorbonne in 1839. Attacked by the clerical party for his views, he was for political reasons deprived of his office in 1852, and imprisoned for three months in 1859. In 1871 he was elected member of the National Assembly for the Department of the Seine.

Vacuum [Lat. *vacuus*, empty]: Ger. (*das*) *Leere*; Fr. (*le*) *vide*; Ital. (*il*) *vacuo*, (*il*) *vuoto*. The condition of empty space; space unfilled by matter. Cf. **PLENUM**, and **SPACE**.

The concepts of the full (plenum) and the empty (vacuum or void) originated very early in the cosmology of Pre-Socratic Philosophy. The Pythagoreans had asserted the existence of empty space beyond the confines of the world (Zeller, *Pre-Socratic Philos.*, i. 408-69, Eng. trans.). This was necessary in order that there might be movement, since to make room for bodies in motion something would have to be pushed outside the world; it was also necessary to account for the possibility of condensation and rarefaction; also to divide things (even numbers) from one another (i. e. if everything was a plenum there would be of necessity complete homogeneity and no distinction). At the same time, in accordance with the highly realistic character of Pre-Socratic philosophy, empty space was identified with air. Parmenides easily recognizes that air is, and, since it is Being, cannot be regarded as NON-BEING (q. v.), which the void would be. Hence everything is full, and accordingly one and homogeneous and at rest—thus admitting that the Pythagorean assertion of the void as necessary for motion and for distinction and plurality is valid (Zeller, op. cit., i. 506, 633-6).

The Atomists accordingly take up the opposite pole of the argument, and in asserting the multiplicity of distinct and moving atoms, assert also the existence of an empty space (*τὸ κενόν*) which separates them and in which they can move about (Zeller, op. cit., ii. 210-20). Empedocles, on the contrary, denied the existence of a vacuum, but supposed that the qualitatively different elements had pores in them, so that the elements are able to mix with one another indefinitely and thus produce the appearance of change and of indefinite variety. Anaxagoras attempts by a more thoroughgoing qualitative mixture of beings to deny the void and yet uphold change and distinction. Plato arrives at the abstract generalization of pure or empty space, which is Non-being, and as the void, the all-receptive (*πανδεχής*) background of the creative energy, which, through being first distinguished into geometrical figures, becomes the framework of the physical world (Zeller, *Plato*, 305-7, Eng. trans.). In the existent physical world there is no void, for the spherical limit of the universe, being continuous, holds all within pressed together (*Timaeus*, 58-60), so that as to nature Plato agrees with Empedocles and Anaxagoras, while returning to the Pythagoreans to get a metaphysical empty space. (This conception of it as correlative to geometry, and thus the mean term between the physical and mathematical, was largely influential in displacing the physico-metaphysical conception of the vacuum by the mathematico-metaphysical conception of pure SPACE, q. v.) Aristotle undertakes an explicit and extensive refutation of the atomic theory of the vacuum: according to him space is the limit of the

including body with reference to the included ; and hence, of course, where there is no body there can be no space. Specially ingenious is his statement (against the Atomists) that not the plenum but the void is incompatible with motion. The void would be absolutely homogeneous in all directions, without distinctions of place, and there would be in it, therefore, nothing which could give a body any definite movement (which implies place) and nothing to bring a body ever to rest (Zeller, *Gesch. d. griech. Philos.*, ii. 399-401). Strato agreed with Aristotle in his polemic against the Atomists, but still asserted the void as necessary to account for certain phenomena of light and heat. Outside the world, however, there is no empty space. The Stoics reversed this position. Space within the world is simply the limits of bodies, or the distance between the limits of a body ; but beyond the world there exists an absolutely empty and infinite space. After this time, the conception is best treated in connection with that of space, save to remark that Descartes, by identifying matter with extension, reduced the conception of the vacuum to a self-contradictory absurdity. In general, it may be remarked that the conflict regarding plenum and void is part of the larger conflict between a mathematical-logical construction of nature which tends to identify space with the ultimate basis of the material (as Plato and Descartes), and a mechanico-physical one, like Atomism ; or, logically, it has to do with the relation of the discrete and continuous ; metaphysically, with the question of the finite and infinite. (J.D.)

Vague (in logic) [Lat. *vagus*, rambling, indefinite]: Ger. *unbestimmt*; Fr. *vague*; Ital. *vago*. Indeterminate in intention.

A proposition is vague when there are possible states of things concerning which it is intrinsically uncertain whether, had they been contemplated by the speaker, he would have regarded them as excluded or allowed by the proposition. By intrinsically uncertain we mean not uncertain in consequence of any ignorance of the interpreter, but because the speaker's habits of language were indeterminate; so that one day he would regard the proposition as excluding, another as admitting, those states of things. Yet this must be understood to have reference to what might be deduced from a perfect knowledge of his state of mind; for it is precisely because these questions never did, or did not fre-

quently, present themselves that his habit remained indeterminate. (C.S.P.)

Vaiçeshika Philosophy: see ORIENTAL PHILOSOPHY (India).

Valentinus. Supposed to be an Egyptian, who lived in Alexandria and Cyprus. Taught in Rome, 140-60 A.D. He was founder of the Gnostic sect of Valentinians. He taught, among many others, Ptolemaeus, Axionicus, Heracleon, and Secundus.

Validity [Lat. *validus*, strong]: Ger. *Gültigkeit*; Fr. *validité*; Ital. *validità*. The possession by an argumentation or inference of that sort of efficiency in leading to the truth, which it professes to have; it is also said to be valid.

Every argument or inference professes to conform to a general method or type of reasoning, which method, it is held, has one kind of virtue or another in producing truth. In order to be valid the argument or inference must really pursue the method it professes to pursue, and furthermore, that method must have the kind of truth-producing virtue which it is supposed to have. For example, an induction may conform to the formula of induction; but it may be conceived, and often is conceived, that induction lends a probability to its conclusion. Now that is not the way in which induction leads to the truth. It lends no definite probability to its conclusion. It is nonsense to talk of the probability of a law, as if we could pick universes out of a grab-bag and find in what proportion of them the law held good. Therefore, such an induction is not valid; for it does not do what it professes to do, namely, to make its conclusion probable. But yet if it had only professed to do what induction does (namely, to commence a proceeding which must in the long run approximate to the truth), which is infinitely more to the purpose than what it professes, it would have been valid. Validity must not be confounded with *strength*. For an argument may be perfectly valid and yet excessively weak. I wish to know whether a given coin is so accurately made that it will turn up heads and tails in approximately equal proportions. I therefore pitch it five times and note the results, say three heads and two tails; and from this I conclude that the coin is approximately correct in its form. Now this is a valid induction; but it is contemptibly weak. All simple arguments about matters of fact are weak. The strength of an argument might be theoretically defined as the number of *independent* equal standard

unit arguments upon the other side which would balance it. But since it is next to impossible to imagine independent arguments upon any question, or to compare them with accuracy, and since moreover the 'other side' is a vague expression, this definition only serves to convey a rough idea of what is meant by the strength of an argument. It is doubtful whether the idea of strength can be made less vague. But we may say that an induction from more instances is, other things being equal, stronger than an induction from fewer instances. Of probable deductions the more probable conclusion is the stronger. In the case of hypotheses adopted presumptively on probation, one of the very elements of their strength lies in the absence of any other hypothesis; so that the above definition of strength cannot be applied, even in imagination, without imagining the strength of the presumption to be considerably reduced. Perhaps we might conceive the strength, or urgency, of a hypothesis as measured by the amount of wealth, in time, thought, money, &c., that we ought to have at our disposal before it would be worth while to take up that hypothesis for examination. In that case it would be a quantity dependent upon many factors. Thus a strong instinctive inclination towards it must be allowed to be a favouring circumstance, and a disinclination an unfavourable one. Yet the fact that it would throw a great light upon many things, if it were established, would be in its favour; and the more surprising and unexpected it would be to find it true, the more light it would generally throw. The expense which the examination of it would involve must be one of the main factors of its urgency.

Returning to the matter of validity, an argument professing to be necessary is valid in case the premises could not under any hypothesis, not involving contradiction, be true, without the conclusion being also true. If this is so in fact, while the argument fails to make it evident, it is a bad argument rhetorically, and yet is valid; for it absolutely leads to the truth if the premises are true. It is thus possible for an argument to be valid and yet bad. Yet an argument ought not to be called bad because it does not elucidate steps with which readers may be assumed to be familiar. A probable deductive argument is valid, if the conclusions of precisely such arguments (from true premises) would be true, in the long run, in a proportion of times equal to the probability which this

argument assigns to its conclusion; for that is all that is pretended. Thus, an argument that out of a certain set of sixty throws of a pair of dice about to be thrown, about ten will probably be doublets, is rendered valid by the fact that if a great number of just such arguments were made, the immense majority of the conclusions would be true, and indeed ten would be indefinitely near the actual average number in the long run. The validity of induction is entirely different; for it is by no means certain that the conclusion actually drawn in any given case would turn out true in the majority of cases where precisely such a method was followed; but what is certain is that, in the majority of cases, the method would lead to *some* conclusion that was true, and that in the individual case in hand, if there is any error in the conclusion, that error will get corrected by simply persisting in the employment of the same method. The validity of an inductive argument consists, then, in the fact that it pursues a method which, if duly persisted in, must, in the very nature of things, lead to a result indefinitely approximating to the truth in the long run. The validity of a presumptive adoption of a hypothesis for examination consists in this, that the hypothesis being such that its consequences are capable of being tested by experimentation, and being such that the observed facts would follow from it as necessary conclusions, that hypothesis is selected according to a method which must ultimately lead to the discovery of the truth, so far as the truth is capable of being discovered, with an indefinite approximation to accuracy. (C.S.P., C.L.F.)

Value: see WORTH.

Value (economic) [OF. *value*, from Lat. *valere*, to be worth]: Ger. *Werth*; Fr. *valeur*; Ital. *valore*. An estimate of what a price ought to be.

The word value is used in a number of different meanings, but this idea of a permanent standard or cause of price, as distinguished from a temporary or accidental phenomenon, lies at the basis of them all. Sometimes value is used in the sense of utility; for instance, when we say that an article has a value to the owner out of all proportion to the amount for which he can sell it. This sense of the term was characterized by Smith as 'value-in-use.' Modern writers avoid this term of Smith's, and say 'degree of utility' (Jevons) or OPHELMITY (q.v., Pareto). The marginal degree of utility, or

value-in-use, is by many called 'subjective value.'

Sometimes value means purchasing power in the abstract as distinct from concrete measures of that power; for instance, we may say that an article has value, though we do not know what its price may be. Sometimes it means purchasing power measured in commodities instead of in money (Fawcett). Sometimes it means average probable price. When we say that a certain article is selling at present below its real value, we may thereby mean that in the long run it will generally command a higher price than at present. But in the commonest sense of the term (which is present in the minds of many reasoners who think they are using other definitions) the word value means a proper and legitimate price as distinct from an unfair or extortionate one. Value thus becomes an ethical term—as distinct from price, which is a purely economic one. A price is a fact; a value, a judgment. A theory of prices puts us in a position to explain the transactions of commercial life; a theory of value undertakes to determine their advisability or morality. Cf. WORTH.

We may thus have as many different theories of value as there are theories of business ethics. But these views fall under two main heads: the commercial theory, which bases value upon what the buyer is willing and able to offer for an article; and the socialistic theory, which bases its estimate of value upon what the article has cost the seller in toil and sacrifice. Down to the time of Jevons the advocates of the socialistic theory had the advantage of offering a clear standard instead of a confused one. There must be, said Aristotle and all the Aristotelians, some common element in the different things whose value is measured one against another; and the only discoverable common element is labour. This, said they, is the real standard. This view was brought out with great emphasis by Karl Marx. But Jevons and his successors, by giving precision to the conception of marginal utility, showed that there was another standard or common element, just as good from a metaphysical standpoint and far more consonant with the facts of commercial life. This so-called Austrian theory of value is nothing more than the commercial theory carried out to its logical conclusion. It holds that the value of an article is the price which it will command under a system of free and intelligent competition. Under these circumstances the

market price represents the temporary value of the article, and the 'normal price' its permanent value.

Literature: HADLEY, Economics, chap. iii; MARX, Das Kapital, i. (1867); WIESER, Der natürliche Werth (1889). (A.T.H.)

Value (ethical): see WORTH (ethical).

Value (in physical science). A number or symbol which expresses the amount or measure of a mathematical quantity; especially a quantity represented by an algebraic symbol; that which answers the question how great is a magnitude or how much is a quantity.

It is distinguished from the word quantity in that the latter is used for the concept in general, as time, space, or weight; while value designates the number or symbol which specifies some definite amount of the quantity. Thus, if t represents a time, we should say that 7 seconds, or n seconds, was the value of t in a special case. Cf. QUANTITY. (S.N.)

Vanity: see PRIDE.

Variable Error: see ERRORS OF OBSERVATION.

Variable (and **Constant**) **Quantity** [Lat. *variabilis*, apt to change]: Ger. *variabel*; Fr. *variable*; Ital. *variabile*. A magnitude or quantity which is conceived to be indeterminate or capable of assuming an indefinite number of values, while some other quantities remain constant (called invariables). (S.N.)

If x may have any one of a specified set of values, it is called an *indeterminate*. If, on the other hand, it is supposed to take these values successively in any specified order, it is called a *variable*.

The assemblage of the values which an indeterminate or variable is free to take is sometimes called its *domain*.

Thus if x is free to take any of the values 1, 2, 3, and these only, it is an indeterminate, and the assemblage 1, 2, 3 is its domain; it becomes a variable if we think of it as taking successively the value 1, the value 2, the value 3, the value 1, &c.

We are free at any time to assign to an indeterminate or variable any particular value which belongs to its domain; but it then ceases to be an indeterminate or a variable and becomes a *constant*.

It should be added that the distinction between indeterminates and variables is not always regarded. Both are commonly called variables, and are covered by the definition given above. (H.B.F.)

Variation [Lat. *varius*, different]: Ger. *Variation*; Fr. *variation*; Ital. *variazione*.

VARIATION

(1) CHANGE (q. v.); (2) DIFFERENCE (q. v.). See the other topics VARIATION, also MODIFICATION AND VARIATION (mental), and VARIATIONAL PSYCHOLOGY. (J.M.B.)

Variation (in biology). Diversity or dissimilarity between organs or qualities that are homologous.

The importance of variation in biology depends on the fact that differentiation of organisms, which is the essence of evolution, must originate in individual dissimilarities. Out of one species several can arise just because every species varies in several directions. Some authors use the term variation in a slightly different sense. Starting with the assumption of a stable specific centre or type, variation is, for them, deviation from that type. It is better to adopt the term deviation for this idea of departure from the type, and to reserve the term variation for the broader conception of unlikeness. Variation is sometimes contrasted with MUTATION (q. v.), mutation being employed for such variation as is of phylogenetic importance. But this distinction is a theoretical one which cannot be utilized in ordinary discussions; for we do not always know what variations are and what are not of phylogenetic importance. Variation as an abstract term is not commonly used in the plural. It is, however, common to speak of one variation or more, by which is meant one differing condition or more: we shall let the word variant stand in this meaning. The term 'a variation' (variant) is sometimes confounded with a variety. While a variant is a particular condition, a variety is a community or an incipient species all the members of which deviate in the same direction from the typical species. Thus, the woodland bison is a variety of the American bison.

The variants of organisms are of a number of types, and may be classified in several ways. Perhaps the most significant classification is into trivial variants and sport variants. Trivial variants are the slight differences that distinguish man from man, or one leaf of a tree from another leaf. Sport variants are those great differences that occasionally crop out and impress themselves strongly upon the progeny of the sport. As examples may be cited hornless cattle, hairless mice, and long-tailed horses. The sport variant may be either 'normal' or 'abnormal'; but there is no sharp distinction to be drawn between these words, as we shall see later, for what is abnormal for one species is often normal for another species.

A second method of classifying variants is into meristic and substantive. Meristic variants have to do with the number of parts and their symmetry; whereas substantive variants relate to the actual constitution or substance of the parts themselves. This classification is that of Bateson. It is, however, not altogether satisfactory, because variation in number is frequently correlated with variation in quality. Thus, variation in number of the teeth of mammals is also a variation in quality, and the number of vertebrae in a fish is correlated with the size of the fish. A third method of classifying variants is into integral and graduated. Integral characters are such as can be counted; graduated variants are such as are expressed by measurement; e.g. the spines on the back of a prawn, the grooves on a scallop-shell, the rows of scales on a fish, are integral variants. The stature or weight of man, the colour of the eye, the strength of the arm, are graduated variants. Finally, variation may be either individual or partial. Individual variation deals with the differences between the characters of individuals. Partial variation deals with the differences between the multiple organs of a single individual. For example, the stature of man is a case of individual variation; the diameter of the scales of an individual fish is a case of partial variation.

The method of studying trivial variation is, in general, the method of measurement or of counting, and the statistical treatment of the data so obtained. See VARIATION (statistical treatment of). The method of studying sport variation is rather that of description and comparison. The facts of extra vertebrae and ribs, of supernumerary fingers and toes in man, of extra digits on the horse's leg, first become significant when we compare the abnormal with the normal conditions in other species. For nothing is more striking than the fact that what is abnormal for one species is often normal for some other. The human abnormality of thirteen ribs is a normal condition in the chimpanzee. The hairless house-mouse finds its counterpart in *Heterocephalus*, a hairless rodent of South Africa.

The two classes of variation, trivial and sportive, have distinct meanings for evolution. Trivial variation is universal, and that very universality makes it *a priori* probable that it has a significance for evolution. The modern selectionist believes that it affords sufficient material to permit, in time and under careful selection, of all those differences

among animals and plants with which we are acquainted. In favour of the theory that evolution takes place by the selection of the ordinary fluctuations about the type, we have (a) the experience of breeders of domesticated animals and plants, (b) the facts of specific or racial difference among some animals in nature, and (c) certain facts of paleontology. (a) The experience of breeders demonstrates that extremely careful selection of minute differences can bring about considerable changes. We see in America the process of selection taking place at fanciers' shows, where each animal is scrutinized with great care, its 'defects' or deviations from an ideal type marked against it on a score card, and then the individual having fewest defects given a prize, as a result of which the price it can command for breeding purposes is greatly increased. Within a few generations any ideal, within limits, provided it remains constant, can be reached. As a result of selection, the proportion of sugar in the sugar beet has been raised unit by unit, from ten per cent. to eighteen per cent. and over. But the process has been a slow one. (b) The fact that the variation of certain animals is correlated with their distribution in nature supports the view of the importance of trivial variation in evolution. As we pass from the east coast to the north-central States of America we find the individuals of various species of birds, mammals, and insects changing gradually from section to section. This has been shown for the fox squirrel, for certain mice, for wasps, and various other insects. There is little question but that climatic conditions have caused the variation in these cases. The qualities of colour are as graduated as the climate is. (c) Many paleontologists are able to construct series of fossils showing almost infinitesimal gradations from one species to others; and some prominent paleontologists have been led by the facts of their science to conclude that evolution proceeds by the selection of trivial variants. In view of all this evidence we can hardly deny the importance that such selection has for evolution.

Yet these trivial variants are not the only ones that play a rôle in evolution. De Vries (1901) has gone to the extreme of denying that trivial variations have any part to play in the origin of species. The improvement of the sugar beet has not made a new species of it. The moment selection, by which the improved condition is maintained, is abandoned

the form reverts to the primitive condition. The improvement of races of poultry or pigeons does not even carry us outside the race with which we started. Although the evidence is historically deficient, it is highly probable that the most striking characters of our domestic fowl have arisen suddenly as sports, which have been preserved by selection. Thus the Dorking fowl is polydactyl, the Polish fowl has a cerebral hernia, the Bantam breed is a dwarf, the rumpless fowl has a monstrous tail, the frizzled fowls have feathers that curl backwards, the sooty fowls are melanic. Darwin himself suggests the origin of these races from sports. He says (*Variation of Animals and Plants under Domestication*, i. 242), 'Fanciers . . . do not sufficiently regard the probability of the occasional birth, during the course of centuries, of birds with abnormal and hereditary peculiarities,' &c.

But we have more direct evidence in the known origin of varieties of plants from sports or 'bud variations.' Thus the nectarine arose suddenly from the peach; likewise the willow-leaved English cherry arose as a sport. Indeed, such a practical as well as theoretical horticulturist as Bailey (as below, 118) says, 'The person who is wishing for new varieties should look critically to all perennial plants . . . for bud variations or sports.' Bateson (as below) has laid great stress on sports as of phylogenetic importance among animals. He finds that in many cases the measurement of an organ fluctuates not about one mode merely, but about two, intergrades being few in number. Thus variation is often discontinuous, and this discontinuity is the beginning of that discontinuity which is typically found between two 'good' species. For example, Bateson finds that the length of the forceps in a lot of earwigs gathered in one restricted locality (Farne Islands) fluctuates about two centres or 'modes' at 3.5 mm. and 7 mm. respectively. I was interested to see whether naturalists have actually found distinct species of earwigs which differed chiefly in the length of the forceps. The recent synopsis of the Forficulidae by Bormans and Krauss (1900) afforded the opportunity. I find repeated cases where closely related species, inhabiting neighbouring but not coincident districts, are distinguished chiefly by the circumstance that the male in the one case has long forceps and in the other case short ones. Thus the potentiality of two species displayed by the earwigs of the Farne Islands has become realized in other species. Likewise, there is

in plants a tendency towards discontinuity in variation: for Ludwig has shown that the ray-flowers of the Compositae tend to group themselves around certain centres. That paleontological evidence cannot be called in to support the view of saltatory evolution is due, not to the fact that great breaks do not occur between fossil species (for such breaks are indeed the prevailing thing), but rather because it cannot be denied that intergrades may have existed.

[For the opposed view that 'sports' have little place in evolution, see MUTATION, and cf. NATURAL SELECTION.—J.M.B.]

Laws of Variation. These have been formulated by Darwin, and some have been added more recently by Bateson.

(1) *No part varies alone, but always in correlation with some other part.* This law of correlation in variation is of the greatest importance. It was early recognized by the French anatomists, and was the basis of their laws of compensation and balancing of growth, and was the justification of Cuvier's attempt to reconstruct the skeleton of an entire animal from a few bones. That Cuvier met with so little success was due rather to his lack of knowledge than to any difficulty in the law of correlation. Recently a method of measuring correlation exactly has been worked out by Galton and improved by Pearson. See VARIATION (statistical treatment of). We can now express precisely the degree of correlation and its sense, whether direct or inverse, between any two measured organs. And so far it appears that there is correlation between almost all organs of the body, even those that are morphologically remote. The index of correlation is an index of morphological kinship or of physiological interdependence.

(2) *Multiple, rudimentary, and lowly organized structures are especially variable.* Bateson has added the law that *the organs that stand at the end of a series are more variable than those that occupy a middle position*; for example, the back molar teeth of man are the most variable of the molars, also the last of the gill-slits of vertebrates, and the extremes in the series of ocellar markings of butterflies.

(3) *A part developed in any species in an extraordinary degree or manner, in comparison with the same part in allied species, tends to be highly variable.* This law has been tested quantitatively by W. L. W. Field (1898), in the case of the corrugated margin—an extraordinary character—of the hawk-moth,

Thyreus Abbotti. The corrugated margin was found to be the most variable dimension of the wing.

(4) *Specific characters are more variable than generic ones.* This has been tested quantitatively by E. T. Brewster, who has found that it holds in a large series of cases of human dimensions, as well as those of the lower animals.

(5) *The species of large genera and those species that have a wide range are especially variable.*

(6) *Secondary sexual characters are highly variable.* Darwin refers especially to the greater variability in the plumage of male gallinaceous birds, which exhibits marked sexual characters,—the females of these birds being without marked sexual plumage.

(7) *The variations of one species are often in the direction of a second species or of an ancestral species.* The latter phenomenon is very commonly seen when breeding domesticated animals, and is called reversion.

(8) *Abnormal outgrowths of bilaterally symmetrical animals tend to be symmetrical and often double.* Bateson has shown this to be true for the appendages of Crustacea and insects and for mammalian bones.

The foregoing laws are still empirical. The work of the future is not merely to multiply such laws, but to simplify their expression.

The causes of Variation. Under this head Bateson in his great work on variation has only the remark: 'Inquiry into the causes of variation is as yet, in my judgment, premature.' We can, in the opinion of the present writer, state certain causes of variation with the express reservation that they are not universal causes, but only partial ones.

(a) *The size of organs increases with use and diminishes with disuse.* This is a well-known fact, but the degree of dependence in any case has not been exactly determined, and it is an unsettled question whether the fact has any phylogenetic significance [i.e. by HEREDITY (q.v.) or otherwise: cf. ORGANIC SELECTION.—J.M.B.].

(b) *External factors, especially climate, modify the individual,* particularly its superficial colour. Cases have been already cited illustrating this law. The effect of poor nutrition is especially marked in the case of plants.

(c) *Crossing and hybridizing bring about new combinations and are thus causes of variation.* Often the combinations are not strictly intermediate between the parents, but are

in accordance with the law of reversion and other less well-recognized laws.

(d) *The very complexity of the developmental processes makes it impossible that the course of development should ever be twice exactly alike.* This is sufficient to account for trivial variation, which follows the law of probability. Some individuals fall short of the specific mode, others develop beyond it. Thus the variants may be merely different ontogenetic stages (Eimer).

All causes of variation fall, indeed, into three general categories; namely, causes inherent in the germ-plasm; causes dependent upon the complexity of the developmental processes; and external causes. The external causes act either directly—that is, chemically or physically—or indirectly as stimuli to which the protoplasm responds by more or less adaptive modifications. We cannot deny, in fact there is some reason for thinking, that all three of these categories take part in evolution; but the first and third are doubtless the more effective. (C.B.D.)

In the treatment of variation, confusion arises from failure to distinguish the following forms: (a) 'indefinite,' 'fortuitous,' or 'ataxic' (subject to 'chance' or following the law of probability); (b) 'definite' or 'determinate' (in some respect not following the law of probability as respects distribution). The latter may well be again divided into (1) 'autotaxic' (determinate variation due to intrinsic vital tendencies to development, as held by all forms of vitalism), and (2) 'taxonomic' (determinate variation caused by external causes of any sort). (J.M.B.)

Variation (statistical treatment of). Cf. VARIATION (in biology).

The characters by which a species of animals is defined are chosen by zoologists in one of two ways. In describing a species, of which many individuals can be examined, some attempt is made to formulate a plan of structure, common to all individuals of the species, and differing from that found among individuals of other species. In the case of rare species, the description is often a mere statement of the chief characters which distinguish a single individual from individuals of other species. The result in either case is the establishment of a mental diagram or 'type,' which can be compared with other mental diagrams of the same kind (cf. Huxley, *The Crayfish*, 1880, chaps. v, vi). For purposes of classification, and for most of the purposes of comparative morphology, these mental 'types' of species are necessary and sufficient; for other purposes they are altogether inadequate.

In a large series of individuals belonging to the same race or species, probably every one presents a general resemblance to the 'type,' but no single individual is *exactly* like it, each one differing from the type and from its fellows by larger or smaller peculiarities. Such individual peculiarities are called variations. The production of variations is a per-

VARIATION

fectly normal process, so that a race or species is characterized not only by the occurrence of a prevalent structural type, but by the extent and frequency of deviations from that type. In many cases it is possible to find a formula which expresses with considerable accuracy both the type and the variability of a species under given conditions of life. Such a formula will probably be found for all cases of variation; and it forms the proper basis for the study of selection, inheritance, and other factors of the process of evolution. The statement of the typical character of a species should also be based upon it.

Determination of the type. The 'typical' condition of a character in a species may be determined in various ways, which may be illustrated by an example. The prawn (*Palaemonetes varians*) occurs abundantly in fresh and brackish water throughout Europe. Examination of 1,434 specimens (male and female) from a small estuary near Plymouth (England) showed the following result:

3 individuals had 7 dorsal teeth.			
89	"	6	"
681	"	5	"
533	"	4	"
103	"	3	"
23	"	2	"
2	"	1	"

For many descriptive purposes it is useful to take as the type the condition which occurs most frequently, or the *mode* (Pearson), which is in this case about five teeth. For other purposes it is convenient to take the *mean* or *average*. In the 1,434 prawns recorded, there were altogether 6,449 dorsal teeth; the sum of all the dorsal teeth, divided by the number of prawns, gives the *mean* number of teeth, or the number which each prawn would have if the whole number of teeth in the group were equally divided among the individuals. In this case $\frac{6449}{1434} = 4.497$; and since any projection from the rostrum is called a tooth, this is an example of the very numerous cases in which individuals exactly like an average or mean type cannot occur. Another way of determining the type, which is useful in many cases, is to arrange all the individuals in order according to the condition of some character, and to determine the condition of that character in the individual at the middle of the series. The *median* value, obtained in this way, is intermediate between the *mean* and the *modal* values, except in special cases. (For examples of the use of median values see especially Francis Galton, *Natural In-*

heritance, 1889, and various papers by the same writer in *Proc. Roy. Soc.*)

The difference between the *mean* and the *modal* type is sometimes greater than in the case just mentioned. The clover (*Trifolium repens*) gives rise occasionally to flowers in which one or more florets are raised above the rest, by a prolongation of the axis of the flower. In a series examined by De Vries:

325 flowers had 0 florets raised above the rest.					
83	"	1	"	"	"
66	"	2	"	"	"
51	"	3	"	"	"
36	"	4	"	"	"
36	"	5	"	"	"
18	"	6	"	"	"
7	"	7	"	"	"
6	"	8	"	"	"
1	"	9	"	"	"
1	"	10	"	"	"

The *modal* number of raised florets is nearly 0; but the *mean* number is 1.454; and in this case a description, in which the *mean* is taken as the 'type,' conveys a totally different impression from a description of the *modal* type. The *median* type lies, of course, between these extremes.

When the variations from the type are distributed with sensible symmetry, the values of the *mean*, *median*, and *modal* types sensibly coincide. Examples of this condition are frequent in human characters (cf. Galton, loc. cit.; Quetelet, *Lettres sur la Théorie de Probabilité*, 1846, and others). J. H. Baxter has given measurements of the height of 25,878 recruits in the United States army; and in these men the *mean*, *modal*, and *median* heights are all sensibly 66.7 inches. (The table is too long for insertion. Cf. *Medical Statistics of the Provost-Marshal-General's Bureau*, i, 1875, and for a discussion cf. Pearson, *Philos. Trans.*, 1895, A, 385.)

The majority of races agree with the examples cited, in the fact that there is *only one modal type* (at least for each sex). In some animals and plants, however, there are two or more conditions of 'maximal' frequency in every race; examples are the long- and short-styled forms of many species of *Primula*, the two forms of male in many arthropods, the three forms of flower in the loosestrife (*Lythrum salicaria*), and many others. In some plants especially there seems to be a tendency to the production of a great number of 'modes.' As an example may be quoted the number of flowers with a given number of ray florets in 17,000 specimens of *Chrys-*

VARIATION

anthemum inodorum, counted by Ludwig (Botanisches Centralbl., lxiv, No. 1, 1895).

Ray Florets.	Frequency.	Ray Florets.	Frequency.
43	...	2	812
42	...	3	1147
41	...	0	1790
40	...	14	3650
39	...	16	1568
38	...	16	856
37	...	28	625
36	...	24	525
35	...	186	479
34	...	346	455
33	...	307	383
32	...	187	427
31	...	183	148
30	...	196	65
29	...	294	36
28	...	377	13
27	...	375	9
26	...	614	2
25	...	602	

These cases of multimodal variability cannot at present be described by any statistical formula, and they will therefore be neglected in what follows. It is important to remember that they exist, and that a statistical theory which fails to include them is incomplete.

Deviations from the type. In attempting to find a measure of the frequency and extent of deviations from the type, it is convenient to take the *mean* value of the character as type, rather than the *modal* or *median* value, when the three do not coincide. The methods adopted may be best illustrated by an imaginary example, chosen for simplicity of computation. Consider, therefore, three bundles of sticks, *A*, *B*, and *C*, each containing fifty sticks; and let sticks of various lengths occur in each bundle with the frequencies given in the table:

Length.	No. of sticks of given length.		
	<i>A</i>	<i>B</i>	<i>C</i>
16 inches	1	6	-
15 "	6	2	7
14 "	10	3	11
13 "	16	28	14
12 "	10	3	11
11 "	6	2	7
10 "	1	6	-

The distribution is in every case symmetrical, so that the *mean*, the *mode*, and the *median* are alike 13 inches in each case; but the extent and frequency of deviations from the type is not the same in any two groups. The frequency of deviations from the type in these groups may be compared by Galton's method of quartiles (see below), by the *mean deviation*, or by the *moment coefficients*. The mean deviation is the worst of these measures.

It is found by taking all the deviations from the mean which occur (*counting deviations as always positive*), and dividing the sum of the deviations by the whole number of observations. Thus in column *A*, the mean being 13 inches, a deviation of 3 inches occurs *twice*, a deviation of 2 inches occurs *twelve* times, and a deviation of 1 inch *twenty* times. The mean deviation is therefore

$$\frac{(3 \times 2) + (2 \times 12) + (1 \times 20)}{50} = 1 \text{ inch.}$$

Treating the other groups in the same way, it will be found that the mean deviation of *B* and *C* is also = 1 inch. The groups were chosen to illustrate the small value of the mean deviation, for purposes of comparison.

The 1st, 2nd,...*n*th *moment* of a series of observations about its mean is found by taking the 1st, 2nd,...*n*th power of every deviation which occurs, *having regard to sign*, and adding all the quantities so obtained together. The magnitude of the sum obtained depends partly on the range and relative frequency of variations, partly on the number of observations. The *moment coefficient*, found by dividing the moment by the number of observations, depends only on the range and frequency of variation. Moment coefficients are conveniently denoted by the letter μ , with a suffix indicating the moment referred to: thus μ_2 means the 2nd, μ_3 the 3rd moment coefficient, and so on. From the definition of the mean, $\mu_1 = 0$ in all cases; the frequency and extent of deviations from the mean are roughly indicated by the magnitude of μ_2 , while the symmetry of their distribution is indicated by μ_3 . Thus in the series *A* of sticks,

$$\mu_2 = \frac{(9 \times 2) + (4 \times 12) + (1 \times 20)}{50} = \frac{86}{50}; \text{ in}$$

$$B, \mu_2 = \frac{130}{50}; \text{ in } C, \mu_3 = \frac{78}{50}. \text{ It will be seen}$$

that these numbers are a better indication of the differences between the three groups than that given by the 'mean deviation.' In each of these groups, since a positive deviation is always balanced by a negative deviation of equal extent, μ_3 is clearly = 0; and this is the proper test of symmetrical distribution.

As examples of the way in which μ_3 approximates to the value 0 in biological statistics, we may take Baxter's data for human stature, already cited, as an example of nearly symmetrical distribution: in these measurements, $\mu_3 = -1.3$; in most observed cases it is much larger.

VARIATION

The direct calculation of moments about the mean becomes very laborious when the mean is not a whole number; for simple indirect methods of doing this, see Pearson, *Philos. Trans.* (1895), A, 345-51, or a summary of Pearson's formulae in Davenport, *Statistical Methods, with Special Reference to Biological Variation*, 1899.

A knowledge of the mean, the mode, and the first three moment coefficients about the mean, give some knowledge of 'typical' character, and of the way in which deviations from it occur: for many purposes, however, as in all questions of heredity, selection, &c., it is necessary to form a complete picture of the relative frequency with which all deviations from the type occur. A mere table of figures cannot be remembered, and few persons can grasp the significance of such a table, even when it is before them. It is easier, therefore, to represent the frequency of variations by means of a geometrical figure. As an example we may take the variations in the number of Müller's glands found by Davenport in the right fore-leg of 2,000 female pigs, observed in Chicago. Among these:

15 pigs had 0 Müller's gland on the r. fore-leg.					
209	"	1	"	"	"
365	"	2	"	"	"
482	"	3	"	"	"
414	"	4	"	"	"
277	"	5	"	"	"
134	"	6	"	"	"
72	"	7	"	"	"
22	"	8	"	"	"
8	"	9	"	"	"
2	"	10	"	"	"

In order to represent these results graphically, we proceed as follows: in a straight line *AB* (Fig. 1) we choose a fixed point *A*, and divide the line to the right of *A* into eleven equal parts, of convenient length, which we number from 0 to 10. Now, whenever we find a pig with no Müllerian glands, we construct a rectangle, of base equal to the length of one division of our scale, and of some convenient height. We place this rectangle with the middle of its base at the point 0 of our scale. If we find a second pig with no Müllerian gland, we erect a similar rectangle on the top of the first. If we find a pig with ten Müllerian glands, we erect a similar rectangle with the middle of its base over the number 10 on our scale, and so on in every case. The result is a series of rectangular columns, such that the *area* of every column represents a certain number of pigs, and the *position* of the column shows the number of Müller's glands possessed

by these pigs. The record of pigs with no Müller's gland, and of those with one, is given in Fig. 1, and a record of the whole series, on a smaller scale, by the continuous line in Fig. 2.

The only essential characters of the diagram formed by the continuous line in Fig. 2 are these: its whole area contains as many units of area as there are pigs in the observations recorded; and the horizontal distance of each unit of area from the point *A*, chosen as origin

Fig. 1.

Fig. 2.

of measurements, indicates the number of Müllerian glands possessed by the pig which the unit of area records; the rate at which the number of pigs changes in passing from the class with one number of Müller's glands to the class with another number may be estimated by the slope of the line joining the middle of the top of one column to the middle of the top of the next; that is, by the angle between *AB* and such a line as *CD* (Fig. 1). Now, by methods described in works on the Integral Calculus, it is possible to construct

a curved figure, such that its moment coefficients about its mean ordinate have fixed values, while the tangent to the curve at any point has a known inclination to the base-line. The curve, whose equation is

$$y = 47.24 \left(1 + \frac{x}{3.796}\right)^{3.784} \left(1 - \frac{x}{14.248}\right)^{14.201},$$

where x is measured from the modal value, has its first four moment coefficients about its mean identical with those of the observations, and its mean is in the same position; further, the tangent to this curve at any point makes an angle with the base-line very nearly equal to that made by a line joining the tops of the two appropriate rectangles. If this curve be divided into vertical strips, along the lines which separate the rectangles of Fig. 2, the area of a strip of the curve will be found to be very nearly equal to that of the corresponding rectangle. The curve is drawn as a dotted line in Fig. 2, but the scale of the diagram is too small to give a fair picture of the agreement between the two.

In terms of such a diagram as this, values of the mean, median, and mode, which cannot occur in actual animals, have a definite meaning. Thus the median number of Müller's glands is given by the abscissa of the ordinate which bisects the area of the curve; the modal number is the abscissa of the maximum ordinate of the curve; the mean number is the abscissa of that ordinate of the curve about which the first moment = 0; and the *quartile deviations* are given by the abscissae of the ordinates which bisect the two halves of the curve on each side of the median ordinate.

The advantage of replacing the system of rectangles, or the table of numbers, by a simple formula which depends upon only a few constants is clear. Such a formula is a means of economizing mental effort, and should be judged only as a means of expressing simply the facts of variation. There is, however, a relation between all those formulae which have hitherto been found to express the facts of organic variation. The characters of individual animals, belonging to any race or species, depend upon a complex series of circumstances, which we cannot know accurately in any given case, although we can learn with a determinable degree of accuracy how often any particular character will occur in a large series of animals. Phenomena of this degree of complexity are the subject-matter of the theory of chance; and for reasons developed in treatises on chance, the formulae ex-

pressing the frequency with which all magnitudes of a particular character occur among animals, in all cases which have yet been expressed in a simple way, are expressions for curves, such as that we have just discussed, the areas of successive vertical strips of the curve representing the successive values of the terms of the series

$$\frac{pn(pn-1)(pn-2)\dots(pn-r+1)}{n(n-1)(n-2)\dots(n-r+1)} \left\{ 1 + r \cdot \frac{qn}{pn-r+1} + \frac{r \cdot r-1}{1 \cdot 2} \cdot \frac{qn(qn-1)}{(pn-r+1)(pn-r+2)} + \frac{r \cdot r-1 \cdot r-2}{1 \cdot 2 \cdot 3} \cdot \frac{qn(qn-1)(qn-2)}{(pn-r+1)(pn-r+2)(pn-r+3)} + \dots \&c. \right\},$$

where $n > r$, and $p+q=1$.

The well-known binomial expression for certain kinds of chance is clearly a special case of this series; for when $n = \infty$, the series becomes $(p+q)^n$. When $p=q$, the terms of $(p+q)^n$ are given by the areas of successive strips of the simple symmetrical curve, so much used by physicists and others in tabulating errors of observation, whose equation is

$$y = \frac{1}{c \cdot \sqrt{\pi}} e^{-\frac{x^2}{c^2}},$$

where $c = \sqrt{2 pqr}$.

The more complicated expressions for cases in which p and q are not equal were first formulated by Karl Pearson (loc. cit.).

The theory of chance was first seriously applied to the formulation of human characters by Quetelet. Later, Francis Galton greatly extended Quetelet's work, and applied the theory of CORRELATION (q.v.) to the study of HEREDITY (q.v.). The treatment of inheritance, introduced by Galton, gave the first possibility of numerically estimating one of the most important factors in any theory of evolution: his work dealt at first only with those cases which could be formulated by the simple symmetrical 'law of error' just referred to. The more general expressions given by Pearson (*Philos. Trans.*, 1895, 1896, 1897; *Proc. Roy. Soc.*, 1898, and elsewhere) have made it possible to apply Galton's methods more generally, and to formulate in a fairly simple way a large number of facts concerning variation.

The formulae expressing the correlation between two or more organs in one body, or between an individual and two or more ancestors, cannot be discussed here. For these the reader should consult Galton's *Natural Inheritance*, in which the foundation of the

whole method is laid down, and Pearson's *Grammar of Science* (2nd ed., 1900), which contains an admirable account, in very simple form, of all numerical problems connected with the theory of evolution.

Literature: besides the indications given, see VARIATION (in biology). (W.F.R.W.)

Variational Psychology: Ger. *Variationspsychologie*; Fr. *psychologie variationnelle*, *psychologie des variations*; Ital. *psicologia variazionale*. That department of PSYCHOLOGY (q. v.) which treats of mental variations.

It is recommended that this term be used to cover the smaller fields of INDIVIDUAL and FOLK PSYCHOLOGY (see those terms), in which variations are respectively individual and racial or tribal, and also that of specific or typical differences. See TYPE (mental).

Among the greater general problems are (1) the correlation of variations, as illustrated in the work in CRIMINAL (q. v.) psychology and anthropology and the investigations of the GENIUS (q. v.); (2) the statistical treatment of mental variations in close connection with the corresponding work in biology and sociology; (3) investigation of the origin of mental variations and modifications through heredity, education, social environment, &c.; (4) the extent, origin, and tests of mental types. These classes of problems justify the use of a broader name; they have had little treatment, but considering the objective and quantitative methods which may be applied to variations, they offer, as do the analogous problems in biology, most important results. See VARIATION (different topics). (J.M.B., G.F.S.)

Variety (in biology) [Lat. *varietas*, difference]: Ger. *Varietät*; Fr. *variété*; Ital. *varietà*. A variety or race is a subdivision of a species, marked by certain recognizable characteristics, which are constant, so that the variety is more or less permanent. When the variety occurs in certain localities, and not in the whole territory inhabited by its species, it is called a 'geographical variety.'

Literature: CH. DARWIN, *Origin of Species*; and *Animals and Plants under Domestication*; DAVENPORT, *Statistical Methods in Biology* (1900); the literature of SPECIES (in biology). (C.S.M.)

Variety in Unity: see UNITY OF VARIETY.

Varro, Marcus Terentius. Lived between 115 and 25 B.C. The learned friend of Cicero, and representative of philosophical eclecticism with Stoicism especially prominent. He wrote forty-one books called 'Antiquitates.'

Vaso-constrictor: see VASO-MOTOR NERVES.

Vaso-dilator: see VASO-MOTOR NERVES.

Vaso-motor Centre: Ger. *Gefässzentrum*, *vasomotorisches Centrum*; Fr. *centre vasomoteur*; Ital. *centro vasomotore* (or *vasomotorio*). An ill-defined region of the medulla oblongata, laterally of the fourth ventricle, which is concerned in maintaining the arterial tone of the body.

It seems not to be concerned with vaso-dilator impulses, and must not be regarded as exclusively responsible for vaso-constrictor impulses, for this function is in part performed by the spinal cord at large. It is rather an initiatory and co-ordinating centre for all vaso-motor processes. Cf. VASO-MOTOR NERVES. (H.H.)

Vaso-motor Nerves: Ger. *Gefässnerven*, *vasomotorische Nerven*; Fr. *nerfs vasomoteurs*; Ital. *nervi vasomotori*. Nerves which are concerned with the regulation of the calibre of the arteries, by innervating the muscular coats of the blood-vessels, and hence with the distribution of the blood. (H.H.-C.F.H.)

We distinguish two kinds, vaso-dilator and vaso-constrictor fibres. The latter send impulses to the muscular coats of the arteries (especially the minute vessels) and normally keep them in a state of tonic contraction. They originate in the lateral cornu of the spinal cord, and pass out through the ventral roots to the sympathetic ganglia, from which they distribute to the arteries *via* the sympathetic nerves or along recurrent branches to the spinal nerves. See NERVOUS SYSTEM (sympathetic). Stimulation of these fibres produces pallor; their inhibition produces flushing. These vaso-constrictor impulses are more or less under the control of the VASO-MOTOR CENTRE (q. v.) of the medulla.

The vaso-dilator fibres are not so thoroughly integrated into a single system as the vaso-constrictor, nor do they have so important a part to play in controlling the circulation. They arise in various parts of the central nervous system and are distributed by way of the ventral roots.

Closely related to the general vaso-motor system are the nerves regulating the rate and strength of the heart-beat. Three classes here deserve mention.

The inhibitory nerves of the heart arise in the medulla, pass out through the vagal portion of the spinal accessory nerve, and then into the vagus. Their action is to suppress the action of the heart. They resemble the

vaso-constrictor nerves of the general vaso-motor system.

The accelerator or augmentor nerves to the heart arise in the spinal cord and pass out to the sympathetic ganglia and thence to the heart. They seem to correspond to the general vaso-dilator system.

The depressor nerves diminish blood-pressure by reflex action on the vaso-motor centres. More specifically, an afferent nerve passing from the heart to the vaso-motor centre of the medulla *via* the vagus. Its function is to inhibit the vaso-constrictor nerves of the body, thus lowering the blood-pressure and relieving the heart. (H.H.)

Vaso-motor System: Ger. *Gefäßsystem*; Fr. *système vasomoteur*; Ital. *sistema vasomotore*. The entire vaso-motor system consists of the following parts (cf. the preceding topics):

(1) Chief vaso-constrictor centres (and probably vaso-dilator centres) situated in the medulla, about the level of the seventh nerve (rabbit).

(2) Medullated nerve-fibres passing from this centre out *via* motor roots of nerves (white *rami communicantes*) to the ganglia of sympathetic system.

(3) Similar subordinate centres in the spinal cord.

(4) Vaso-motor nerves proper, which arise as neurites of sympathetic cells and pass as non-medullated fibres to be distributed to the blood-vessels.

It has thus far been impossible to demonstrate (physiologically) vaso-motor nerves in the brain or spinal cord.

Vaso-constrictor nerves were first discovered by Claude Bernard (1851) and Brown-Séquard (1852). Vaso-dilator nerves were first demonstrated (1855) by Schiff; and the whole subject relating to influence of nervous system over the circulation was most thoroughly studied by Ludwig. (C.F.H.)

Vedānta Philosophy: see ORIENTAL PHILOSOPHY (India).

Vedic Religion [Sansk. *veda*, knowledge]: Ger. *Religion der Vedas*; Fr. *religion védique*; Ital. *religione vedica*. The ancient religion of the Hindus, of which Brahmanism was the matured form, consisting in the worship of deities who were personifications of the forces or aspects of nature.

Literature: see BRAHMANISM, and ORIENTAL PHILOSOPHY (India). (A.T.O.)

Vegetable: see PLANT; and cf ANIMAL.

Velleity [Lat. *velle*, to be willing]: Ger.

Velleität; Fr. *velléité*; Ital. *velleità*. The conative aspect of a mental process or content. See CONATION.

A term not in general use. (J.M.B., G.F.S.)

Velocity [Lat. *velocitas*, from *velox*, swift]: Ger. *Schnelligkeit*; Fr. *vitesse*, *vélocité*; Ital. *velocità*. Rate of movement of a body in space.

For the unit of measurement of velocity, and the unit of acceleration of velocity, see UNIT (of physical measurement, velocity).

(J.M.B.)

Vengeance: Ger. *Rache*; Fr. *vengeance*; Ital. *vendetta*. The act or other circumstances in which REVENGE (q. v.) issues.

One may feel revenge but stop short of vengeance, which always terminates, or is intended to terminate, on the appropriate object. (J.M.B.)

Ventricle [Lat. *ventriculus*]: Ger. *Ventrikel*, *Hohlraum*; Fr. *ventricule*; Ital. *ventricolo*. One of the cavities or coelia within the brain derived from persistent portions of the original embryonic medullary cavity. Cf. the figures given under BRAIN.

In combination coele is preferable, as in diacoele (= third ventricle). There are the two paracoeles (lateral ventricles), the diacoele (third ventricle), the mesocoele (in mammals, &c., forming the aqueduct of Sylvius, or iter), the metacoele (fourth ventricle). The so-called pseudocoele (fifth ventricle) is not a true ventricle, but a cleft left by the partial concrescence of the two plates of the lamina terminalis.

In comparing the nervous elements of the brain with those of a peripheral sensory epithelium it is necessary to remember that the ventricular cavity, and hence the endymal surface, is morphologically an invaginated part of the original external epithelium. The apparent outer surface of the brain is thus morphologically internal and the ventricular aspect is external. (H.H.)

Ventriloquism [Lat. *venter*, belly, + *loqui*, to speak]: Ger. *Bauchreden*; Fr. *ventriloquie*; Ital. *ventriloquio*. The production of sounds, mainly by a modification of the respiration, by which the voice appears to come not from the person speaking, but from a distance, or from an opposite direction.

It is of interest as an illusion of the direction and quality of sound, and has probably been important in the history of magic, and the pronouncements of oracles. An assumed form of speech of similar character occurs as an occasional symptom in delusional insanity,

and seems connected with systematized delusions. (J.J.)

Veracity [Lat. *verax*, truthful]: Ger. *Wahrhaftigkeit*; Fr. *vérité*; Ital. *veracità*. The disposition not to deceive another by positive misrepresentation; that is, not to LIE (q. v.).

The appreciation of veracity, especially as regards speech, has varied much in ancient and modern ethics. The Greeks did not include it in the cardinal virtues, or regard it as absolutely and invariably obligatory. Plato gives expression to their estimate of it in the *Republic* (ii. 382), where he distinguishes between the 'true lie' or the 'lie in the soul,' which is hated by both gods and men, and the 'lie in words,' which is, in certain cases, useful and not hurtful, as in dealing with enemies or with friends in a fit of madness or illusion, and in mythology, where we do not know the truth. He also justifies the 'noble' or 'royal lie' (γενναῖον ψεῦδος): the rulers are privileged to lie for the public good (iii. 389, 414). The modern juridical conception of morality as obedience to law has led to a more rigorous enforcement of the duty of veracity. Kant, e.g. in his *Über ein vermeintes Recht, aus Menschenliebe zu lügen* (Abbott's trans., 361-5), maintains the absolute obligatoriness of veracity, since lying, if universalized, contradicts the presuppositions of human intercourse. 'To be truthful in all declarations is therefore a sacred unconditional command of reason, and not to be limited by any expediency.' A single exception would destroy that universality which is essential to a moral principle. On the Jesuitical depreciation of the virtue on the ground that the end justifies the means, see EQUIVOCATION. Cf. also CASUISTRY. (J.S.)

The principles involved in the discussion, besides the psychological and logical ones indicated by the word positive in the definition (explained under LIE) and in the article EQUIVOCATION, would seem to be, or at least to involve, the following: (1) the fact of ethical conflict, the possible dilemma of choosing the lesser of two violations of nominal duties, one of which is unavoidable. This raises the whole question of the relativity of ethical formulations. (2) The possible distinction between duties as social or not, the former springing from social relationships, and in so far getting their entire sanction from social utilities. This distinction would possibly open a door for a 'certain discrimination of higher and lower,' even to those who hold that there are absolute ethical principles. (J.M.B.)

Verbal (in logic) [Lat. *verbum*, a word]: Ger. *verbal*; Fr. *verbal*; Ital. *verbale*. Turning upon the use or meaning of words, as 'verbal argument.'

Applied mainly to arguments, definitions, &c., which involve distinctions of words merely, and are with reference to fact or truth fallacious or meaningless. (J.M.B.)

Veridical Hallucinations: see TELEPATHY, *passim*.

Verification [Lat. *verus*, true, + *facere*, to make]: Ger. *Bewährung, Bestätigung*; Fr. *vérification*; Ital. *verificazione*. It is desirable to understand by a verifiable hypothesis one which presents an abundance of necessary consequences open to experimental tests, and which involves no more than is necessary to furnish a source of those consequences. The verification will not consist in searching the facts in order to find features that accord or disagree with the hypothesis. That is to no purpose whatsoever. The verification, on the contrary, must consist in basing upon the hypothesis predictions as to the results of experiments, especially those of such predictions as appear to be otherwise least likely to be true, and in instituting experiments in order to ascertain whether they will be true or not.

These experiments need not be experiments in the narrow and technical sense, involving considerable preparation. That preparation may be as simple as it may. The essential thing is that it shall not be known beforehand, otherwise than through conviction of the truth of the hypothesis, how these experiments will turn out. It does not need any long series of experiments, so long as every feature of the hypothesis is covered, to render it worthy of positive scientific credence. What is of much greater importance is that the experiments should be independent, that is, such that from the results of some, the result of no other should be capable of reasonable surmise, except through the hypothesis. But throughout the process of verification the exigencies of the economy of research should be carefully studied from the point of view of its abstract theory.

When, in 1839, Auguste Comte laid down the rule that no hypothesis ought to be entertained which was not capable of verification, it was far from receiving general acceptance. But this was chiefly because Comte did not make it clear, nor did he apparently understand, what verification consisted in. He seemed to think, and it was generally under-

stood, that what was meant was that the hypothesis should contain no facts of a kind not open to direct observation. That position would leave the memory of the past as something not so much as to be entertained as plausible. (C.S.P.)

Vertebrate [Lat. *vertebra*, a joint]: Ger. *Wirbelthier*; Fr. *vertébré*; Ital. *vertebrato*. Strictly, an animal having vertebrae, but used to designate all members of the sub-kingdom to which animals with vertebrae belong. Cf. INVERTEBRATE.

The lowest fishes (myxinoids and amphioxus, a fish-like animal) present no trace of vertebrae, the axial skeleton comprising only the notochord. (C.S.M.)

The Vertebrata, sometimes called Chordata, all possess a dorsal skeletal notochord at some time in their development.

Literature: GEGENBAUR, Compar. Anat.; WIEDERSHEIM, Vergleichende Anat.; PARKER and HASWELL, Zoology; C. CLAUS, Textbook of Zoology (Eng. trans., 1890). (C.S.M.—E.S.G.)

Vertex [Lat., from *vertere*, to turn]: Ger. *Scheitel*; Fr. *sommet*, *vertex*; Ital. *vertice*, *bregma*. The top or crowning point of the head; the highest point of the human skull when the body is in a perfectly erect position.

It is usually just behind the bregma (*Bg*, in figure given under CRANIOLOGY, q. v.). (J.J.)

Vertigo [Lat. *vertigo*, a turning]: Ger. *Schwindel*; Fr. *vertige*; Ital. *vertigine*. Dizziness, with fear of falling, a confused sensation as of swimming of the head, and apparent motion of outward objects.

Vertigo as a sensation may vary in degree from a slight sense of confusion or instability up to violent reeling and actual falling in an attempt to correct the subjective sensations of apparent motion of surrounding objects. The mechanism, the disturbance of which produces vertigo, is a very complicated one. The special organs of EQUILIBRIUM (q. v.) are concerned, probably, the semicircular canals, and the brain centre for such co-ordinations of equilibrium, situated in the cerebellum. The sensations obtained from this source are co-ordinated with visual inferences of position and movement. Vertigo may be produced in most persons by unusual or violent locomotion, as oscillation in a swing, turning rapidly around on one's heels, ascent or descent in an elevator, the irregular movements of a ship, balloon, or train. Vertigo as the result of drug action is marked in the case of alcohol.

As a symptom of disease, vertigo is of

various significance. It has been associated with pressure upon the brain, concussion or injury of the brain (as by tumours, disturbances of circulation, blows, &c.), particularly in diseases of the cerebellum; with anaemia of the brain from general anaemia or arterosclerosis; its frequency in multiple sclerosis has been noted; it is often a characteristic factor in the epileptic seizure, and in some cases takes the place of such a seizure; it is particularly significant in aural, especially labyrinthine, difficulties, in one form of which (Ménière's disease) the vertigo forms the chief symptom; it is frequent in neurasthenia and related conditions; and it is connected with ocular as well as visceral disturbances.

Ocular vertigo is an unusual disorder, due generally to weakness or paralysis of an ocular muscle, and a consequent false orientation of the body with reference to seen objects. The ocular sensation (as of moving objects) is an important one in all forms of vertigo. Aural vertigo arises from disease in the internal ear, and includes Ménière's disease as one of its severer forms. This disorder, which is often preceded by earache, slight deafness, ringing in the ears, is of a paroxysmal nature. The patient is more or less suddenly seized with intense vertigo, may reel about or fall to the ground; objects seem to move about, and even slight loss of consciousness may occur. Some patients feel impelled to go through circular or backward movements, others are hurled to the ground as by an unseen force. In repeated attacks the same forms of movement are experienced, indicating in some cases a local affection of one canal or group of canals. In most cases there is a succeeding dazed period, often accompanied by pallor, vomiting, and severe physical depression.

The vertigo that is characteristic of neurasthenia is largely of a subjective character, a feeling of swimming and confusion, rarely amounting to reeling or the apparent moving of outward objects. It is generally relieved by assuming a horizontal position, and is associated with states of fatigue. Vertigo of gastric origin is probably not a frequent disorder, although an attack of indigestion, seasickness, and the like, is the occasion or predisposition to vertigo in those liable to these disorders.

Literature: GOWER, Diseases of the Nerv. Syst.; HITZIG, Der Schwindel, in Nothnagel's Spez. Ther., xvii. 2 (2nd ed., 1898). (J.J.)

Vested Rights: see RIGHTS.

Vestige [Lat. *vestigium*, a footprint]; Ger. *Spur*; Fr. *vestige*; Ital. *vestigio*. See VESTIGIAL ORGANS AND CHARACTERS.

Vestigial Organs and Characters. Reduced and often useless organs or characters which, on the theory of evolution, represent the fully functional and useful organs or characters of ancestral animals: a single such organ or character is called a vestige.

(C.L.L.M.—J.M.B.)

This phrase has largely replaced the earlier phrases rudimentary organs and rudiment. It thus distinguishes organs in process of DEGENERATION (q. v., in biology) from organs in process of evolution (cf. RUDIMENT). Darwin discussed the value of such organs as evidence of the transmutation of species. Cf. also ATROPHY.

Since the theory of evolution has become widely accepted, the method of suppression has been discussed. On the Lamarckian hypothesis disuse is itself sufficient to effect reduction of size and complexity, since the effects of disuse are on this hypothesis inherited. Those who reject this hypothesis account for the facts by reversed selection, assuming that the possession of the organ constitutes a disadvantage, by cessation of selection with PANMIXIA (q. v.), and by the principle of economy of growth with INTRASELECTION (q. v.). Weismann has added the hypothesis of GERMINAL SELECTION (q. v.) or a competition for nutriment in the waxing and waning determinants or structural units in the germinal substance, by which the stronger increase while the weaker diminish.

Literature: C. DARWIN, *Origin of Species*; J. G. ROMANES, *Darwin and after Darwin*, ii; WEISMANN, *The Germ-Plasm*; and *Germinal Selection*. (C.L.L.M.)

Veto: see FIAT, and NOLITION.

Vibration [Lat. *vibrare*, to shake]: Ger. *Vibration*; Fr. *vibration*; Ital. *vibrazione*. The rapid rhythmical movement of a body or parts of a body back and forth in a linear path or closed curve. In the latter case the vibration is called circular, elliptic, &c., according to the form of the path.

Movement in one direction is sometimes called a single, and that in both directions a complete vibration. Such a vibratory movement when propagated through a homogeneous medium is called an undulation or wave. Cf. ETHER. (S.N.)

Vicarious Atonement [Lat. *vicarius*, taking another's place]: Ger. *stellvertretendes Sühnopfer*; Fr. *expiation vicariale*; Ital.

espiazione vicaria. That theory of the Atonement which represents it as a substitutionary sacrifice for sin on the part of the Redeemer, by virtue of which the sinner's debt to the divine law is satisfied and the merit of Christ's obedience is imputed to him as the ground of his justification.

The vicarious theory is opposed to the moral theory and presupposes the necessity of expiation. It rests on the notion of substitution, and is the work which was accomplished by Christ in the stead of the sinner.

Literature: see ATONEMENT. (A.T.O.)

Vice [Lat. *vitium*]: Ger. *Laster*; Fr. *vice*; Ital. *vizio*. Gross, and more or less habitual, departure from VIRTUE (q. v.).

Like virtue, vice extends to character, disposition, and habit of life. It is contrasted in degree with moral defect and FAULT (q. v.). See also SIN. (J.M.B.)

Vico, Giovanni Battista. (1668–1744.) Born at Naples, and educated by the Jesuits. Private tutor for several years in the house of the bishop of Ischia; professor of rhetoric in Naples, 1697; royal historiographer, 1735. 'The bold and profound creator of the philosophy of history' (Falckenberg). See Cantoni, *G. B. Vico*.

Victorinus, Marius: see SCHOLASTICISM, I.

Virtual [Lat. *virtus*, strength, from *vir*, a man]: Ger. *virtuell*; Fr. (1) *virtuel*; Ital. (1) *virtuale*. (1) A virtual *X* (where *X* is a common noun) is something, not an *X*, which has the efficiency (*virtus*) of an *X*.

This is the proper meaning of the word; but (2) it has been seriously confounded with 'potential,' which is almost its contrary. For the potential *X* is of the nature of *X*, but is without actual efficiency. A virtual velocity is something *not* a velocity, but a displacement; but equivalent to a velocity in the formula, 'what is gained in velocity is lost in power.'

So *virtual representation* was the non-representation of the American colonies in the British Parliament, which was supposed to be replaced by something. So Milton asks whether the angels have *virtual* or immediate touch. So, too, the sun was said to be *virtualiter* on earth, that is, in its efficiency.

(3) *Virtual* is sometimes used to mean pertaining to virtue in the sense of an ethical habit.

Virtual knowledge: a term of Scotus defined by him (*Opus Oxon.*, Pt. I. iii. 3) as follows: 'Quantum ad notitiam habitualement sive virtu-

alem, primo expono quid intelligo per terminos. *Habitualement* notitiam voco, quando obiectum sic est praesens intellectui [i.e. to the thought] in ratione intelligibilis actu ut intellectus statim possit habere actum elicatum circa illud obiectum. Voco *virtualem*, quando aliquid intelligitur in aliquo, ut pars intellecti primi, non autem ut primum intellectum sive ut totale terminans intellectionem; sicut cum intelligitur homo intelligitur animal in nomine, ut pars intellecti, non ut intellectum primum, sive totale terminans intellectionem. Hoc satis proprie vocatur intellectum *virtualiter*, quia est satis proximum intellecto in actu. Non enim posset esse actualius intellectum, nisi esset propria intellectione intellectum, quae esse ipsius primi, ut termini totalis.

Virtual difference: a term of the doctrine of *formalitates* set forth by Scotus, *Opus Oxon.*, Pt. I. ii. 7. (C.S.P.)

Virtue [Lat. *virtus*, manliness, equivalent to Gr. ἀρετή, excellence]: Ger. *Tugend*; Fr. *vertu*; Ital. *virtù*. Excellence of character, disposition, and habit of life, with reference to generally accepted moral standards. (J.S.—J.M.B.)

The nature of virtue and the classification of the virtues engaged the attention of both the ancient and the mediaeval moralists. Socrates made the moving spring of virtue adequate knowledge of the good, that of vice ignorance of it; and from this view of the nature of virtue he deduced the unity of the virtues, which were simply the different applications of the knowledge of the good. Plato distinguished four cardinal virtues, wisdom (*σοφία*), courage (*ἀνδρεία*), temperance (*σωφροσύνη*), and righteousness (*δικαιοσύνη*). Aristotle, investigating more carefully the psychological nature of virtue, defined it as a habit (*ἔξω*), as distinguished from a mere activity (*ἐνέργεια*). This habit implies deliberate choice or preference, and is in accordance with right reason. Its object or content is the mean (*μεσότης*) between the two extremes of excess and defect. The application of this doctrine to the details of the moral life gives Aristotle his list of virtues, which includes, besides courage and temperance, liberality, munificence, high-mindedness, gentleness, agreeableness, truthfulness, wittiness, and modesty. In addition to these virtues of the individual life, Aristotle recognizes justice and friendship, as the virtues called for by the social relations in which the individual stands to the state and to other individuals. So far, however, account has been taken only of moral or practical virtue, which consists in an established or

habitual control of irrational impulse by reason. Intellectual virtue is the excellent or rational exercise of the rational soul itself. The chief intellectual virtues are speculative wisdom (*σοφία*), which deals with the absolute nature of things, and prudence or practical wisdom (*φρόνησις*), which deals with the relative and changing conditions of human conduct. Aristotle insists upon the intellectual nature of moral virtue, since the latter, in all its forms, presupposes rational insight (*φρόνησις*).

The mediaeval moralists followed Aristotle in his division of virtues into intellectual and moral. To the cardinal virtues of Plato they added the 'theological' virtues. The former they regarded as 'natural,' or 'acquired by human acts'; the latter as 'supernatural,' or 'infused by God.' The cardinal virtues lead only to natural or human happiness; the theological lead to supernatural or divine happiness. 'Habituation,' says Thomas Aquinas, 'contributes to both, but in different ways. It causes acquired virtue; it disposes to infused virtue; and where infused virtue exists, it preserves it and advances it' (*Summa Theol.*, i-ii. q. 92, art. 1, § 1; cf. i-ii. q. 65, art. 2; i-ii. q. 62). The theological virtues are faith, hope, and charity. Faith has special reference to the intellect, hope and charity to the will. The Christian Church further added to the classical list of virtues such additional phases of character as patience and humility.

The question of the fundamental nature and value of virtue was investigated by the Stoics and Epicureans, the former regarding it as an end-in-itself, the latter as the most important means to happiness. The early British moralists were also more concerned with this problem than with that of the good, raising the further questions of the 'sanctions' of virtue, and of its egoistic or altruistic content. Butler's contribution to this discussion is most important. In his view virtue is a following of human nature as a systematic whole, or acting in accordance with the guidance of the higher (rational or reflective) principles — conscience, self-love, and benevolence. Its obligation is intrinsic: man, as a rational being, is a law unto himself.

Literature: that of ETHICS; see also BIBLIOG. F, 2, e. (J.S.)

Virtue (in theology): Ger. *Kräfte* (plural), *Tugend*; Fr. *vertu*; Ital. *virtù*. Those elements of character are virtues which are distinctive of the Christian ideal, as faith, hope, love, submission to the divine will, &c., and which

presuppose, subjectively, the regenerate nature, and objectively, a kingdom of grace in which they are supreme ends.

In mediaeval thought a distinction was made between natural and theological or supernatural virtue, the latter being regarded as a function of divine grace. The Reformation resulted in the abolition of this distinction, and two lines of ethical thinking originated: (1) philosophical ethics, a development of morality on an extra-dogmatic basis; (2) Christian ethics, which sought to develop the science of duty or virtue as a branch of Christian dogmatics. Christian ethics aims at a reconstruction of the whole scheme of duty on a basis of divine grace. All virtues, according to it, are functions of the regenerate nature. See *ETHICS* (Christian, also for literature). (A.T.O.)

Vision¹ [Lat. *videre*, to see]: Ger. *Gesicht*, *Sehen*; Fr. *vision*, *vue*; Ital. *visione*. The sense whose organ is the eye, whose stimulus is light, and whose nerve is the *opticus*. (J.M.B.)

I. *General*. In the production of visual sensation, several distinct processes in the human organism are involved. In the retina the ether vibrations (which we know to be still ether vibrations when they reach this surface) are transformed into some other form of energy which can be conveyed along the nerves—we know not what form, but at least it must be something very different from light, because vibrations of that degree of rapidity would cause the destruction of delicate nervous tissues. In the occipital lobes of the cortex there takes place, under the influence of this conveyed excitation, some process which is the immediate condition of the visual sensation. Before reaching the cortex, the optic fibres pass through intermediate ganglionic stations (quadrigeminal bodies, optic thalamus), but it is not known that these have any essential part to play in the sensation that enters consciousness—they may have no other function than to effect reflexly the motions of pupil, ciliary muscle (accommodation), convergence, &c., which are essential to effective vision (Fig. 1). When the cortical centres have been destroyed, no visual sensation is possible, but the same thing is not true concerning the retina: the

basal ganglia and the retina may both be thrown out of action by disease, and sensation may nevertheless persist; as a preceding symptom of MIGRAINE (q. v.), which seems to be due to a spasm in the cerebral, or more rarely the retinal, circulation, and of epilepsy, there are very commonly experienced subjective visual sensations, which are sometimes in the form of rings and balls, like the pressure-phosphenes, or zigzags in incomplete curves (fortification-figures, scintillating scotomata), but which sometimes have the appearance of natural objects or of human figures. These frequently enter the field of vision at one side, and the patient instinctively turns the head and the eyes to follow them:

Fig. 1. Hypothetical scheme for the optical conducting paths. *OO*, cortical centre; *MM*, mid-brain; *Ch*, chiasm; *RR*, retinal terminations; \uparrow , centripetal paths; \downarrow , centrifugal paths; \rightarrow , lateral connecting paths.

this shows that the cortical process carries with it what is essential to spatial localization without the participation of the retina. But it also shows, as was plainly affirmed by Gowers before the recent work of Flechsig on the subject, that there are secondary cortical centres (association centres, or, as they may perhaps be designated, perception centres) where the immediate data of visual sensation are worked up into more complicated forms. As still more conclusive proof of the possible cortical origin of visual sensation may be mentioned a remarkable case in which a man stricken blind in both eyes saw a sudden flash of fire just before the on-coming of unconsciousness, and in which dissection showed

¹ In this article, points that are of special interest to the psychologist will be discussed at some length. For the ordinary details in regard to the working of the eye as an optical instrument, see the textbooks of physiology, as Bowditch in Howell's *Amer. Text-book of Physiol.* (2nd ed., 1900).

degeneration of the optical cortex, with everything below the cortex in a perfectly healthy condition (*Subj. Lichtempf. bei totalem Verluste des Sehvermögens, m. Zerstörung d. Rinde beider Hinterhauptslappen*, Diss., Marburg, 1895, P. Schirmer). This proves to perfection that chemical changes in the cortex, although not brought about by excitation coming in from below, suffice to affect consciousness (and with spatial attribute as well as simple sensation quality). On the other hand, there are cases on record of most disturbing visual sensations (rings and balls of colour) due to irritation of the cortex caused by a diseased retina which was entirely blind to light—as was proved by the fact that these disturbances ceased when the eye in question was enucleated. (It is therefore impossible to say that what is usually called IDIO-RETINAL LIGHT (q. v.), or the self-light of the retina, is or is not in reality cerebral light; most probably it is of both cerebral and retinal origin, since it is beyond question that internal irritations from either source do, upon occasion, enter consciousness.)

There are, then, aside from the conducting fibres, four separate stations, in general, in the affection of consciousness by external light—the retina, which is, indeed, not only a neuro-epithelial surface, but also a true nervous centre shifted to the periphery (cephalopods, which have, taken together, all the different nervous layers of the human eye, have some of them in the brain and not in the retina)¹; the basal ganglia; the primary visual centres in the occipital lobe; and the final association-centres. Each of these may apparently be excited to its characteristic activity by internal sources of activity, in the absence of incoming stimulation from below.

In the lower animals the visual process is certainly of much less complexity than in the human visual organ; all that is essential to such a process is that there should be some form of reaction to the transverse vibrations of the ether. Any animal in which a portion of the ectoderm is so differentiated as to be a receptive organ for this form of excitation may be said to possess an eye, whether the reaction to the excitation is conscious or unconscious; in certain of the lower forms of animal life the whole surface of the body is obscurely sensitive to light. Sensations of colour (as well as of form), as they exist in

the perfected eye, are modalities of the fundamental luminous sensations, which are without question of rather recent phylogenetic development. Wherever there is an eye with two distinct forms of visual elements, rods and cones, it is probable that there is a sense of colour. Below that, there is no evidence of this aspect of the luminous sensation: many observers have declared that the lower animals have a colour sense, and that they have strong colour-preferences (Graber); but this conclusion is not warranted, for a preference for one region of the spectrum over another may perfectly well be a preference for a particular degree of brightness. Since we have found out that the relative brightness of the different spectral regions is, for ourselves, totally different according as the illumination is faint or bright (the PURKINJE PHENOMENON, q. v.), there is no reason to infer that animals have any sense for actual colour from the fact that they go from one coloured apartment into another, even though these have been made equally bright for the normal human eye. It has lately been found, in fact, that even bees are attracted by odours rather than by any sense for colour: flowers when covered by paper are visited by them just as frequently as if they were exposed to view.

The eye is considered to be the most highly developed of the sense organs, not only because of its comparative perfection as an optical apparatus (the lens is a piece of living matter which approaches the regularity of a solid with mechanically perfected curved surfaces), but also because of the number of different forms in which it effects sensible discrimination. The pressure sense, the heat sense, the cold sense are senses with good local discrimination, but with variation within a single terminal organ for intensity only, without discrimination of quality—we cannot tell whether a given amount of heat comes to us from the infra-red or the red or the yellow rays of the spectrum. In the ear we have discrimination for different objective vibration-rates (the sound-waves) in the form of the different subjective quality attached to notes of different pitch, and to this discrimination is given up the physiological space-discrimination in the auditory organ—namely, the succession of fibres of the basilar membrane; there is left no means of acute local discrimination, and, in fact, in the auditory sense we have no space-discrimination other than by the greater loudness of a sound heard by one ear than by the other, or by a rough difference in quality

¹ The optic nerve is not a nerve, properly speaking, but a portion of cerebral white matter pushed forward (Greef, *Arch. f. Ophthalm.*, xxix. 85, 1900).

Fig. 2. Cones from the different retinal zones (Greef). I, close to the ora serrata; II, 3 mm. from the ora serrata; III, halfway between the ora serrata and the papilla; IV, periphery of the macula lutea; V, macula lutea; VI, fovea centralis.

according as one or another element of a tone is reinforced by the reflecting walls of the meatus auditorius (Angell, *Psychol. Rev.*, 1901).

In the eye we have a far more keen and dominating sense for space than in any other sense organ—so much so that the quality which stands pre-eminently in consciousness for space itself is the retinal spatial quality. In this organ, the distribution of rods and cones within the sense organ is the primary physiological intermediary between physical and subjective space; consequently there is left no very exact means for quality-discrimination within the sense, and, in fact, our subjective reactions to differences of vibration-period in light-waves are very inadequate. The whole gamut of light-waves is responded to by us subjectively with only four different sensation qualities—red, yellow, green, and blue. These are the sensations which are produced in their purity by, about, the wave-lengths $576 \mu\mu$, $505 \mu\mu$, $470 \mu\mu$, and a colour a little less yellow than the red end of the spectrum. For all intermediate wave-lengths we have nothing in sensation except combinations of these hues, or *colour-blends*, as reddish-yellow, blue-green, greenish-yellow, &c., but with this very singular peculiarity, that non-adjacent colour-pairs do *not* give colour-blends (red and green reproduce yellow, and blue and yellow give white, or grey); were it not for this latter circumstance, the confusion in the response to ether-radiation distinctions would be far greater than it is now. Hence we have no means of determining whether the sensation which we get from wave-length $486 \mu\mu$, say, is due to light of that wave-length as an objective cause or to a physical mixture of light of wave-lengths $492 \mu\mu$ and $470 \mu\mu$; in other words, our visual organ, as a means of giving us knowledge regarding the radiations reflected from or emitted by objects, is exceedingly inadequate. It follows from this that we can never have, in the play of colours, intricate aesthetic combinations and involutions corresponding to musical compositions in tones. The sensation elements are far too simple for that; they are like what we should get from a primitive musical instrument with only four strings.

Provision for vibration-period quality being so inadequate as this, and spatial distribution upon the retina being correlated with the highly developed spatial consciousness of the visual sense, what is the physiological mechanism by which four distinct sources of colour-sense are communicated from retina

to brain? Scattered sparsely among the rods (the primitive organ for a non-differentiated luminous sensation) are the cones, which alone, it is probable, provide for the sensation of colour; is a single cone the seat of all four colour-processes, and are all four sets of excitation conveyed from one cone along one optic nerve-fibre to the brain? The physiologists are strongly of the opinion at present that all nerve-fibres convey one and the same sort of excitation, and that conscious distinctions of quality are brought about by different reactions in the cortical cells in which they debouch. But, (1) they have chiefly in mind the simpler structures, where there is nothing against such a supposition (muscle, pressure, auditory sensations)—it is *only* in the sense for colour that occasion arises for making a different assumption, and hence analogy from other cases is entirely without force; (2) it has been too much the custom to think of a nerve-fibre as if it were a simple structure: the recent work of Apäthy has fastened attention upon the fact, apparently forgotten by the physiological theorists, that each nerve-fibre is composed of a number of fibrillae; hence there is nothing against the doctrine of specific energy, if that be applied to fibrillae instead of to fibres, in supposing that a single cone is a laboratory for, and a single fibre a conductor for, several different sorts of excitation; (3) the only anatomical difference that exists between the rods and the cones (for the long, fine, closely pressed together cones of the fovea are not cone-shaped) is exactly this—that communication with the continuous bi-polar cell is on the one hand by a simple knob, on the other by a group of distinct processes (Figs. 2, VI); this suggests that the difference between a black-white series, on the one hand¹, and sensations in

¹ Black may well be the sensation attached to the resting-stage of the cortical visual process. A state of non-excitation from the external world does not, in the case of the other senses, need to enter consciousness; but in the visual sense the spatial attribute is of extreme consequence, and if we were unconscious of objects which send to us no light there would be lacunae in the retinal spatial field which would be most disturbing. This state of things actually occurs in the case of localized lesions in the cortical visual field; the ophthalmologists distinguish between *negative* and *positive* scotomata—in the latter (disease of retina or optic fibres) a black spot is seen in place of a portion of the external field; in the former, nothing is seen. This fact alone goes far to prove that black is purely a cortical excitation, which enters consciousness as a *mark* of the absence of retinal excitation.

four different tones, on the other hand, has its physiologico-anatomical basis in the provision for disjunct communication between cone and bipolar cell, which is had by means of the several different fibrillae groups of the cone-base. If it were the case that one fibre could convey one form of excitation only, then the four simple colour-tones would have to be mediated by four different contiguous cones (three, in the original Young-Helmholtz theory, which was based solely upon physical, not at all upon psychological considerations). Helmholtz himself, in the last (second) edition of the *Physiologische Optik*, has given up this view, and regards the several photochemical processes which underlie colour as taking place all in a single cone. If one cone mediates one colour only, then a point of purple light, so small that its image falls upon a single cone, should look, as the image passes over the retina, now red and now blue according as it strikes one or another of the visual elements that are fitted to respond to it. This and similar phenomena were announced by Holmgren to occur, and were taken by him as being complete confirmation of the Young-Helmholtz theory, so far as this point is concerned; but later experiments from the laboratories of Hering and of König show that such loss of true colour does not take place. Schoute (*Zeitsch. f. Psychol.*, xix. 251) gives good reasons for believing that, in such experiments, the image formed is actually as small as calculation from the constants of the eye would imply. It is true that Graefe (who has examined two perfectly fresh human eyes with the aid of the most modern methods of staining, &c.) finds that the cross section of a foveal cone is $2\ \mu$; it has usually been given as $4\ \mu$, and hence it is possible that the images formed were not small enough to affect individual cones in the fovea. But, on the other hand, images so small as this cannot fall upon more than one cone at a time in the extra-macular region, and here, too, the phenomenon of incomplete response does not take place. The chief consideration by which the physiologists uphold the similar character of all nerve-fibre transmissions is the fact that only one set of electrical reactions occurs, no matter what nerve is involved; but it would be as safe to infer that any two chemical reactions were the same in kind because they were attended by the same production or abstraction of heat (Hering). The question is of fundamental consequence, and it is hardly worth while to devise colour theories

until after it has been settled; nevertheless, the physiologists proper and the physiologists for the eye rest content, seemingly, each in his own belief, with very little counter-discussion. It cannot be too much insisted upon, meantime, that the question as it regards the eye must be settled upon its own merits, and not from analogy with other sorts of nerve-fibre, where the assumption of such complexity is not demanded by the facts.

Literature (to I): v. HELMHOLTZ, Handb. d. physiol. Optik (2nd ed., 1896); see also under OPTICS. (C.L.F., E.B.T.)

II. LIGHT [ME. *light*, *liht*, AS. *leoht*]: Ger. *Licht*; Fr. *lumière*; Ital. *lume*. The sensation produced by the action upon the retina of a radiation in the ether consisting of trains of transverse waves called light. The sensation is not produced except by waves within a certain range of velocity.

The periods and wave-lengths of these waves may be measured by interference and diffraction methods. The velocity of the waves has been measured by various observers. It has been found that in order to produce the sensation light these waves in the ether must have periods lying between 13×10^{-16} and 25×10^{-16} of a second. Expressed in different words, the wave-lengths of these waves which affect the retina in the method described must lie between 750 and 390 millionths of a millimetre; for the velocity of the waves is nearly 3×10^{10} centimetres per second. A source which emits waves of such periods as to produce light is called a 'source of light'; for instance, a candle, the sun, an electric lamp, a glow-worm. The radiation itself is often, but incorrectly, called 'light.' If this radiation is examined by a spectroscope, it is noticed that the eye perceives different colours in different portions of the spectrum. Consequently, waves of different periods produce different colour-sensations. Four absolutely distinct colours (together with their intermediate colour-blends) are discernible in the spectrum; these are, in the order of decreasing wave-lengths, red, yellow, green, and blue.

In the radiation from any source of light there are also present waves whose periods do not lie within the limits necessary for the production of the sensation light. Some of these trains of waves have periods longer than those of 'light-waves'; others, shorter. The former are called infra-red radiations, and may in general be detected by the rise in temperature of such bodies as absorb them;

the latter are called ultra-violet radiations, and must in general be studied by some photographic process.

These waves in the ether all advance with the same velocity independent of their period or wave-length, provided there is not associated with the ether any form of ordinary matter, using this word in an everyday sense. This therefore is the case in interplanetary space. But if, on the other hand, matter is associated with the ether—for instance, if the waves are passing through any ordinary transparent substance such as glass or water—the velocity is not the same as for the pure ether, being less; and further, waves of different periods have different velocities, the shorter waves having in general the less velocity. This accounts for refraction and dispersion.

Waves in the ether are carrying energy; and, when they reach the retina and are absorbed, their energy is used in producing certain (probably chemical) changes which stimulate the nerve-ends. If the waves are emitted by a small source, their intensity at any point varies inversely as the square of the distance of the point from the source.

It should be noted further that the radiation from a source of light will produce definite physical and chemical effects in material bodies if it is absorbed by certain substances or instruments. Illustrations of this are afforded by photographic action or chemical action in general, phosphorescence and fluorescence, rise in temperature and other heat-effects, and so on.

In order to produce a source of light it is in general necessary to have a high temperature, as is shown by a flame, an incandescent or arc electric light, the sun, and so on. There are cases, however, where bodies may be rendered luminous in other ways than this. Illustrations are given by the Welsbach burners, glow-worms, and in general by phosphorescent and fluorescent substances. Other illustrations are given by the production of light by electrical discharges.

In distinction from trains of waves in the ether it is possible to have irregular transverse disturbances which may also affect the sense of sight. There is no doubt but that the Röntgen rays are illustrations of this kind of disturbance, and that they may under certain conditions affect the eye.

(J.S.A.—C.L.F.)

III. THE EYE [AS. *edge*, eye]: Ger. *Auge*; Fr. *œil*; Ital. *occhio*. The end-organ of vision; the mechanism by which vibrations of the luminiferous ether are transformed into the physiological stimulus of visual sensation. (C.F.H.—J.M.B.)

Two important pieces of apparatus for studying the eye are the ophthalmometer (for making various measurements—ophthalmometry—including the curvature of the cornea) and the ophthalmoscope (for viewing the interior of the eye, especially the retina—ophthalmoscopy). (J.M.B.)

A knowledge of both the anatomy and physiology of the eye may be best attained by studying its development in the animal series and in the vertebrate embryo.

Eye-spots in the Protozoa and lowest Metazoa are collections of pigment granules, commonly brownish or reddish, situated in the ectosarc, or (in the Metazoa) in conjunction usually with the cerebral ganglia, or in groups of epithelial cells on the surface of the body. These cells may occur on a level with the general surface, as in some coelenterates, be raised into pigmented papillae, as in the fringes about the mantles and siphons of bivalve molluscs, or drawn below the surface as pigmented sacs or pits, as found in echinoderms, many worms, and in the tips of the tentacles and papillae of numerous molluscs.

It is often stated to be doubtful whether these simple eye-spots give rise to definite sensations of light; the sensations which accompany their reactions to the rays of the spectrum may, for aught we know, be sensations of heat, though there are no known instances among the higher animals (where we can more reasonably infer by analogy their sensations from our own) of a special provision for the *absorption* of heat-producing rays. Moreover, the experiments of Romanes seem to indicate that certain jelly-fishes and echinoderms are sensitive to light and not to heat. It should also be borne in mind that dark pigment is rather an accessory than an essential to vision, as is proved by its absence in albinos as well as in many of the lower animals that are still sensitive to light.

The formation of the eye as a pit lined by epithelial cells lends itself to the development of the accessory structures, lens and other refractive media, iris and cornea, which render visual images possible. Even a simple pit with pin-hole aperture is capable of forming images on the principle of the simple

camera obscura. The secretion of refractive media by the cells forming the pit or sac, and the clearing up of the superficial cells to form a transparent cornea, and their convex thickening to make a corneal lens, are steps which are very easy and which are rapidly taken in the invertebrate series.

In the eyes of invertebrates generally, the cells of the retina, being specialized epithelial cells, retain their original position, i.e. the poles for receiving sensory stimuli point to the exterior, and the basal, or discharging, poles send fibres directly to the brain. In a few cases, notably those of *Pecten* (Patten) and of *Onchidium* (Carrière's Fig. 17), the retinal cells are inverted and the optic nerve-fibres spring from their superficial poles and reach the brain by breaking through the bottom of the optic cup (*Onchidium* and vertebrates), or flow over its rim and thus around to the brain (*Pecten*). These eyes are probably explained by a collapse of the primitive optic vesicle, such as occurs in vertebrates, to form a secondary optic vesicle with double wall. The cells of the external layer would thus be inverted; lens, cornea, and all accessory structures are then formed, as in vertebrates, by cells of the surrounding and overlying tissues.

Position of eyes in the body depends rather upon the animal's needs than on any fixed laws of structural organization. Ability to see food and natural enemies being a most important factor in fitness to survive, eyes are commonly developed in close association with the principal nerve ganglia. Thus eyes may be scattered over the entire back (*Onchidium*), where the chief enemies approach from above, or arranged along the mantle-edge or about the siphons of bivalve molluscs, in which retraction and closure of the shell are the important reactions. In the free-swimming embryos of bivalves eyes are present in the head, but atrophy as the shell closes over them. This is generally true of all the higher animals that live in total darkness, in the deep sea, in caves, in burrows and holes in rocks, showing that they are descended from seeing forms and have been crowded into the darkness. With animals that possess a head and move actively about, eyes are situated uniformly in front, paired, or otherwise grouped (insects and arachnids) about the brain. Their positions in the worms are especially instructive as pointing to the relations obtaining in the vertebrates. In the leeches, for example, the eye-spots occur

one pair in each of several of the anterior segments.

Morphologically the vertebrate retina is a specialized portion of the original wall of the primitive fore-brain vesicle. Since the neural tube in vertebrates is a strip of superficial epithelium folded in and covered over, its cavity represents the external world. The primary optic vesicles arise very early as paired outgrowths on either side of the first cerebral vesicle, carrying its cavity with them. As they reach the skin, the front wall caves inward, or is possibly pushed inward by the thickening of the epidermis to form the lens, and the secondary optic vesicle results with double wall and the cavity of the primary vesicle is obliterated. The location of this cavity is indicated by the surface of juncture of the two walls of the secondary optic vesicle, and it must be remembered that this surface between the rods and cones and the pigment epithelium represents the external world to the cells of the retina. See Plate A (BRAIN), Figs. 7, 8. The outer wall now thickens by growth and division of its cells to form the distinctively nervous layers, while the inner wall remains one cell thick and constitutes the pigment layer of the retina, classed with the choroid by earlier writers. The choroid coat then forms over the convex surface of the retinal cup, homologous with the pia, and is continued in front with the pigment layer of the retina, as the iris (Fig. 3). The epithelial cells immediately over the mouth of the optic vesicle elongate, and sinking below the surface, first as a pit and then as a hollow vesicle separated from the skin, give rise to the fibres of the crystalline lens. This takes its position in the optic cup, nearly filling it in the early embryonic stages. Below, the optic vesicle remains open for a time, a furrow in the stalk which attaches it to the brain continuing outward to the rim of the vesicle as the choroidal fissure. Through this the mesoblastic tissue which is to form the vitreous humour flows in behind the lens, and the fissure growing together completes the cup. From the surrounding mesoblast the sclerotic forms, enclosing the whole in a thick tough coat homologous with the dura of the brain and spinal cord. In front the sclerotic is continued as the cornea, a modified form of connective tissue, transparent and free from blood-vessels. The eyelids, when present, are formed by folds of the integument from above and below the cornea meeting along the

VISION

median horizontal line. These grow together early in the third month and open (man) shortly before birth.

The skin thus turns inward at the edge of each eyelid as the *conjunctiva*, which after following the lid back, palpebral conjunctiva, is reflected over the eyeball as the conjunctiva bulbi and over the cornea as the corneal epithelium. By everting, or by lifting

flow the lids in the form of tears. Ordinarily this is prevented by the oily secretion of the Meibomian glands situated within the lids, which is poured out along their edges. The lachrymal gland is developed in animals above the fishes. The lids are stiffened by dense plates of connective tissue, *tarsi*, and are supplied with muscles for closing, the orbicularis, and opening, the levator palpe-

Fig. 3. Diagram of a horizontal section of the left eye, drawn to scale. (Norris and Oliver.)

the lid away from the eyeball, the limits of the conjunctival sac may be seen. Into the upper temporal portion of this sac the lachrymal glands discharge their secretion, which, by the act of winking, keeps the front of the eyeball uniformly moist, and from the nasal angle the lachrymal duct carries off excess of moisture, except such as may over-

brave, which is a slender muscle attached at the back of the orbit and inserted by a thin flat tendon along the tarsus of the upper lid. Some animals have a similar muscle for the lower lid. A third eyelid, rudimentary in man, as the plica semilunaris, especially developed in birds, the nictitating membrane, consists of a reduplication of the conjunctiva,

situated in the anterior angle. By a special musculature it can be carried quickly back and forth over the exposed portion of the eyeball.

Movements of the eyes are effected in man by six muscles for each eye: four straight muscles, the superior, inferior, external and internal recti; and two oblique, the superior and inferior oblique. See Fig. 4. The eyeball rests on a soft cushion of fat, which fills the orbit, but is separated from it posteriorly by a lymph-sac, the *tunica vaginalis oculi*, or

In the normally formed eye at rest these media suffice to bring parallel rays, or those coming from objects more than two metres distant, to a focus on the retina. As an object approaches the eye, increased convexity of some refracting medium must be attained to bring the more and more divergent rays to the required retinal focus. This is accomplished by the act of ACCOMMODATION (q. v.), which affects chiefly the form of the lens, and is brought about by contraction of the ciliary muscle. This muscle consists of radial

Fig. 4. The muscles of the eye. *A*, axis of the eye; *n*, optic nerve; *o*, foramen opticum; *m*, chiasma nervorum opticorum. Beyond the chiasm the optic nerves become the optic tracts. *i, a, s*, the internal, external, superior recti muscles; *t*, superior oblique muscle; *u*, trochlea. *DD*, axis of rotation of the superior and inferior recti muscles; *BB*, that of the oblique muscles; these make angles respectively of 70° and 35° with the axis of the eye. The external and internal recti move the eye about a vertical axis. (Helmholtz.)

capsule of Tenon, in which it rotates on practically a surface of lymph.

The human eyeball is formed of segments of two spheres: the larger, about one inch in diameter (24 mm.), the posterior opaque sphere, corresponds to the area of the sclerotic, the smaller anterior sphere (16 mm. diameter) to that of the cornea. Beginning in front with the cornea, the refractive media are: the aqueous humour (practically lymph, the anterior chamber being thus a lymph space), the crystalline lens, and the vitreous humour.

and circular fibres, the latter acting as a sphincter for the suspensory ligament of the lens. The radial fibres are attached about the corneo-sclerotic junction and are inserted along the ciliary body of the choroid coat. The action of both parts of the ciliary muscle is thus to slacken the strain on the lens of the suspensory ligament, according to the theory of accommodation advanced by Helmholtz, and the lens, by its own elasticity, tends to assume a more spherical form. The front of the lens especially becomes more convex,

its radius of curvature changing from 10 mm. to 6 mm., while the back surface changes only from 6 mm. to 5.5 mm. More recently Schoen has advanced a quite different theory as to the operation of the mechanism of accommodation (Schoen, 'Der Accommodationsmechanismus,' *Arch. f. d. ges. Physiol.*, lix. 427). See Fig. 5, *a* and *b*.

Fig. 5. The actual mechanism (*b*) of accommodation, illustrated by the mechanical action of hand-pressure on a ball of flexible material (*a*). (Schoen.)

For the normally formed eye (see EMMETROPISM) the power of accommodation makes it possible to focus upon the retina rays of any degree of divergence from parallel to those coming from an object from 10 to 13 cm. from the eye. Nearer than this distance, which is known as the 'near point,' accommodation is unable to bring the rays to a focus. Not infrequently eyeballs are longer in the axis of vision, MYOPIC, or shorter, HYPERMETROPIC, than normal; in which cases parallel rays tend to focus, with the eye at rest, either in front of the retina, MYOPIA (q.v.), or beyond the retina, HYPERMETROPIA (q.v.). Hypermetropic eyes are able to focus parallel rays on the retina by an effort of accommodation, which often causes headaches and other nervous symptoms; but since there is no mechanism by which the lens can be rendered less convex, the myopic eye must be provided with concave glasses, to render the rays more divergent, in order to obtain clear images of distant objects. Practically all eyes are hypermetropic at birth, and generally grow emmetropic. Too great strain upon the mechanism of accommodation in early

years is probably one of the most serious causes in the development of myopia; heredity is another important factor.

Another important defect is due to irregularities in the cornea, or other refractive media. The corneal surface is the one commonly involved, and if it is not spherical, but ellipsoidal, i. e. flatter in one meridian than another, regular ASTIGMATISM (q.v.), rays penetrating it will not be brought with exactness to a focus, but will be united in two focal lines at right angles to each other and at different distances from the cornea. All except certain sectors of the visual field must therefore be represented, with a given accommodation, by indistinct images on the retina. Regular astigmatism may readily be corrected by cylindrically ground glasses. Irregular astigmatism exists when meridians of refracting surfaces are irregularly curved, i. e. are arcs of neither circles nor ellipses, or when the media themselves are not homogeneous. It is impossible to correct such astigmatism by optical means.

Fig. 5 c. Binocular diagram to illustrate astigmatism. By fixating a point a few inches in front of these figures and halfway between them, they can be made to fuse into a single tridimensional figure showing two focal lines at right angles to each other. (Bowditch.)

Spherical ABERRATION (q.v.) is a difficulty encountered in the construction of all optical instruments, arising from the fact that

rays penetrating a lens near its margin are brought to focus sooner than those penetrating near the centre. This is adjusted for in the eye by the iris, which cuts off the marginal rays, and by the structure of the lens itself, which becomes softer, i.e. less strongly refractive, as we pass from the centre towards the margin.

Chromatic aberration, due to the refrangibility of the rays of short wave-length (violet) of the spectrum being greater than that of those of long wave-length (red), is also a defect of the eye as an optical instrument. It may be readily demonstrated by covering one-half of the pupil, when a coloured fringe will appear along a dark line through a bright field, a window-bar against the sky, bluish on one side and reddish on the other. It is compensated for by the fact that, when the eye is accommodated for the middle rays of the spectrum, the violet rays (which will have crossed one another at a focus in front of the retina) will be overlapped by the red rays (which have not yet been brought to a focus), and hence the dispersion circle around the focus of medium rays will be approximately grey in colour, and so overlooked. But if the upper half of the pupil is cut off, only the violet rays from below and the red rays from above reach the retina, and hence coloured fringes are seen.

The retina, the innermost coat, extends over the posterior portion of the eyeball and forward almost to the ciliary body. Here the visual portion ends in a serrated margin, the *ora serrata*. The pigment layer of the retina extends over the ciliary body, and is continued over the back of the iris as the uvea. The colour of the retina in life is light pink, or purplish red, if kept in the dark, owing to the visual purple (Boll), or rhodopsin (Kühne), of the rods.

According to recent descriptions the human retina, and that of vertebrates generally, consists of eight distinct layers: (1) layer of pigment cells, next the choroid coat; (2) layer of rods and cones; (3) external nuclear layer; (4) external plexiform (a term proposed by Cajal and preferable to the term 'molecular' of earlier writers) layer; (5) internal nuclear layer; (6) internal plexiform layer; (7) ganglion-cell layer; (8) layer of nerve-fibres. The so-called internal and external limiting membranes which appear in sections between the nerve-fibre layer and the vitreous humour, and between the outer nuclear and rod and cone layers respectively, are merely the

planes of-termination of the supporting cells, fibres of Müller, of the retina; see Plate I (Vision), Fig. 6 B. The blood-vessels, a central artery and vein, enter and leave by the optic nerve. They are distributed to all layers except the outer nuclear and rod and cone layers; and since the shadows of the retinal capillaries are plainly visible, the actual mechanism for the transformation of light-vibrations into something which gives rise in the brain to visual sensations must lie within these layers. Structurally, the rods and cones are peripheral portions, receiving poles, comparable to sensory hairs or coalesced pencils of sensory cilia, of the originally superficial cells, whose nuclei are those of the external nuclear layer, and whose central, discharging, poles are fibres which break up into terminal brushes in the external plexiform layer. The rods and cones are thus, with little doubt, the real transformers of visual stimuli, the specialized receiving organs for all sensations of light and colour.

From the above description it is clear that light must penetrate six layers of the retina before reaching the rods and cones. This is not of great consequence, since, when alive, the retina is nearly transparent, but in animals generally a certain part of the retina is thickened either along a band corresponding to the image of the horizon line, as in some of the herbivora, or in a round or oval area near the axis of vision, where the retina is most used, the central area or *macula lutea* in man and primates. In man, primates, most birds, and a very few reptiles, amphibians, and fishes, a pit forms in the centre of the thickened area, in which the other intervening layers of the retina and all blood-vessels draw aside and leave the cones directly exposed to the light. The thickened portion is generally known as the *macula lutea*, from its yellow colour, and the pit or depression as the fovea or fovea centralis. While the rods greatly outnumber the cones in the peripheral portions of the retina, the cones grow proportionately more and more numerous as we approach the centre, and in the fovea itself only cones are present. A number of birds, notably among the raptorial and swallows, have two foveas, a temporal fovea for binocular vision and a nasal or median fovea for monocular vision. It is now well established that moving objects are more quickly perceived by the portions of retina rich in rods, and in animals, like the frog, which apparently only see objects in

PLATE I (Vision).

(By the Golgi method.)

motion, the rods greatly predominate even in the central portions of the retina. On the other hand, minute vision of stationary objects is only possible in the fovea.

Sömmerring (*Sm. Th.*, v. 1798) discovered the fovea and considered it a foramen. Buzzi (1796) thought the fovea to be a thin transparent part of the retina.

The optic nerve-fibres gain their medullary sheaths as they pass through the lamina cribrosa of the sclerotic coat. At this point, the porus opticus (optic disk, papilla), all the layers of the retina are forced aside to admit the passage of the nerve, and as vision is consequently also interrupted here, the spot is known as the 'blind spot' (Mariotte's spot, 1668).

Some (Quain) still describe the optic nerve as spreading out within the eyeball as the innermost layer of the retina. This is true (His, Cajal) of but a very few of its fibres, which have been proved to grow from the centres to the retina as possibly motor or associational fibres. Since the researches of His, Martin, and Mall (1890-3) have demonstrated that the optic nerve-fibres, in common with sensory nerves generally, arise as axones of the large ganglion cells and grow centripetally to the optic centres, it would seem advisable to reverse the older descriptions and consider the optic fibres as gathering from all points of the retina, uniting in the optic nerve, and distributing themselves to the optic centres in the brain. In line with this we should also reverse the numbering of the layers of the retina, as is done above.

The optic fibres from the right-hand half of each retina proceed to the right cortex, from the left-hand half to the left cortex, but a small portion of the retina, about coincident with the yellow spot, is doubly provided for, and may preserve its function when either half of the cortex is destroyed (Fig. 7).

The principal axis of the eye is a line joining the centres of curvature of its refractive media. The axis of vision is a line drawn from the fovea to the point looked at. For the eyes at rest or while looking at a distant object the axes of vision of the two eyes are nearly parallel; as the object approaches they converge, the sensations of strain from the oculo-motor muscles furnishing important data in judgments of distance. Additional advantages of binocular vision are increased size of visual field, perception of the depth of points not fixated upon by means of double images, and

correction of errors of one eye by the other. If for the primary position we imagine that the retinal cups be exactly superimposed so that one fovea lies over the other, each point in the superimposed retina corresponds nearly with the point directly beneath it in the other. These are known as 'identical' or corresponding points. All images falling upon identical points of the two retinae are projected into space as single points. The line or plane passing through all such points is called the HOROPTER (q.v.). All points out of the horopter, while we commonly disregard them, form images which are projected, or seen, as double. Standing erect and looking towards the horizon, according to Helmholtz, the horopter stretches out as a line coinciding with the plane of the ground upon which we stand. With each position

Fig. 7. Scheme of the crossing of the optic nerve in the chiasm of man. The visual nerves with their retinal expansions are seen from above; the optic tract of the right side is shaded, that of the left is white.

of the eyes the form of the horopter changes. With the eyes converged, the horopter is a circle passing through the fixation point and the nodal points of the two eyes. This is known as the 'circle of Müller.'

IV. THE EYE AS AN OPTICAL INSTRUMENT. For details in regard to the deflection of ether radiations out of a straight course by means of lenses, see the various textbooks. The eye is essentially a combination of lenses adapted to throwing an image of an external

the corresponding point of a small inverted image. That the image is inverted is of no consequence in our perception of objects. If an arrangement of pins in the shape of an arrow be pressed upon the arm, we can tell whether the head of the arrow be pointed up or down, because we have always seen the surface of the arm, and felt it with the other hand, and hence we know it as an object, as well as by its subjective local signature. But we know nothing about the back surface of the eye, nor about the images that fall upon it. We do, however, know about its front

Fig. 8 a. Camera obscura of a photographic apparatus. *A B*, object; *D*, diaphragm for shutting off too divergent rays; *L*, lens for refracting the rays so that they will form the image *a b* upon the sensitive plate *R*. (After Norris and Oliver.)

Fig. 8 b. The eye as a camera. *A B*, object; *C*, cornea, where the rays undergo a first refraction; *D*, the iris, which acts as a diaphragm for shutting off too divergent rays; *L*, lens, where the rays are again refracted; *R*, retina, upon which the image *a b* is projected; *a' b'* represents the surface of a hypermetropic eye, and shows that the rays are not completely focussed, and that the image is consequently blurred and indistinct; *a'' b''* represents the surface of a myopic eye, and shows a similar condition. (After Norris and Oliver.)

object upon a delicate expansion of the optic nerve, the retina (Figs. 8 a and b). It is in effect a dark chamber, or *camera obscura*, like that of a photographic apparatus, in which the light from any object within its field is thrown by refracting media upon a background so placed that the rays diverging from any given point converge to

surface, from the eyes of others, and from our own as seen in a mirror, and the only apparent want of harmony that could exist would be if our eye had to turn downwards in its socket to see an object which we have to reach the arm up to. Consciousness does not descend (like a person!) into the eyeball along the optic tract and nerve, and view the image upon the

VISION

retina. If she saw anything as an object, it would be, probably, the image which is transferred from the retina to the occipital lobe; in that, however, a re-inversion takes place (Henschen), and she can there, if she likes, gaze contentedly at a (chemical) image which is right side up. But there is no more reason that she should feel the inversion of the images upon the retina than that she should be aware of the coming to a point of all the direction-lines within the crystalline lens, or of the semi-decussation of the visual currents in the optic chiasm.

By computing the effects of each of the lenses in turn, the total effect of the several

plane passes from the first to the second principal plane in a direction parallel to the axis, and thence proceeds in a direction parallel to the line which joins the starting-point to the first nodal point. The refracting surfaces of the eye may be still further simplified, and a 'reduced eye' constructed, which is sufficient for practical purposes. This is regarded as consisting of a single refracting surface of these constants:

Index of refraction . . .	1.33
Radius of curvature . . .	5.017 mm.
Distance from front surface of cornea to principal point (regarded as one) .	2.148 mm.

Fig. 8 c. The lines of the eye. (Modified from Helmholtz.) F, F'' , conjugate foci; h, h'' , principal points; K, K'' , nodal points; l, l'' , refractive surface of the reduced eye.

refracting surfaces of the eye might be separately calculated, but it has been shown that for any system of centred spherical surfaces there exist six points, known as cardinal points (first and second focal, first and second principal, first and second nodal points), such that if the position of these has been determined, the direction of all rays of light through the system may be readily traced. The optical axis is the common perpendicular to the several refracting surfaces, and the focal and principal planes are planes perpendicular to this axis through the corresponding points. The rule for the construction of images is then this: any ray emanating from a point on the first focal

Distance from posterior surface of lens (forward) to nodal point04 mm.
Distance from first principal focus to anterior surface of cornea . . .	28.918 mm.
Distance from anterior surface of cornea to second principal focus . . .	22.231 mm.

The optical power of the eye is equal to 50.8 dioptries. The optical power of any lens is the reciprocal of its focal length; the dioptre, or unit of optical power, is the power of a lens with a focal length of 1 metre.

The principal lines and points of the eye are given in Fig. 8 c. The point of regard is

the fixation point of the eye at any moment; it is, under normal circumstances, the same for both eyes, and hence it is also the point of convergence. The rotation point is that point in the eye which remains fixed as the eye moves about in the socket. It is 11 mm. behind the plane through the edge of the cornea, or 13.5 mm. behind its vertex, and 10 mm. in front of the back surface of the sclerotic coat. Its position is fixed by the shape of the back half of the eyeball, which is flatter than the front half—it is, in fact, the centre of this half-ellipsoid. The eye can rotate, with effort, 50° to each side, and 45° up and down; the field of regard (the sum of the points which can be made fixation points) is therefore, in extent, a right angle in the vertical direction, and a little more than that in the horizontal direction. The field of sight is the extent of space that can be seen with the eye at rest. The line of regard is the line from the point of regard to the centre of rotation. The movement of the eye may be resolved into rotations about three axes—the sagittal, which coincides with the primary position of the line of regard (its position when, with the body erect and the head held symmetrically, we look at the middle point of the distant horizon), the transverse and the vertical (which are at right angles to it and to each other). A line of direction is the unbroken ray of light through any point of an object looked at and through the nodal point of the eye, to the corresponding point of the image on the retina. The principal line of direction, that through the fixation point, is called the line of sight; it makes an angle of 5° with the optical axis (the eye is an optical instrument which is not well centred—the point of acute vision, the fovea, is not at the meeting-point of the optical axis with the retina). The line of regard is inside the line of sight, as the rotation point is presumably in the optical axis, and hence medianwards from that line. The plane of regard is the plane through the lines of regard of the two eyes. Cf. EYE-MOVEMENTS.

The centre of the blind spot is about 15° nasalwards from the fovea. Its cross section is from 3° to 9°, on the average 6°, in the eye of Helmholtz 7°, or from 1.4 to 1.7 mm. on the surface of the retina, that is, about the size of a man's face at the distance of two metres. For the determination of the size upon the retina x of the image of an object X which is at a distance p , in mm., from the anterior surface of the retina, we have, from

the consideration of the similar triangles involved (since the distance from the nodal point to the retina is approximately 16 mm., and from the nodal point to the anterior surface of the cornea 7 mm.), the formula—

$$x = X \frac{16}{p + 7}.$$

All optical instruments for the formation of images must have power of adjustment, for objects at different distances, sending rays of light through a fixed system of lenses, form images at different distances. This adjustment may be secured by moving the receiving surface further back, as is done in the *camera obscura* of the photographic apparatus, or by increasing the index of refraction of one or more of the media, or by a diminution of the radius of curvature of one or more of the surfaces. The first of these means was formerly the one supposed to be made use of in the eye, the eyeball being assumed to be elongated for viewing near objects. But it is now supposed that the change takes place in the shape of the crystalline lens, brought about by means of the ciliary muscles; from a teleological point of view the lens would be superfluous were it not for its performing this function, for the amount of refraction that takes place at its surface could be produced by a slightly greater curvature in the cornea. The far-point for the normal emmetropic eye (the furthest point at which objects can be distinctly seen) is at an infinite distance; the near-point varies with age, and in early adult life is from 10 to 13 centimetres from the eye. No accommodation is necessary for objects more than two metres distant.

V. ACTION OF LIGHT ON THE RETINA.

That the retina of certain animals was sometimes red had been remarked before, but it was discovered by Boll (1876) that this red colour is bleached out by light, and that it becomes restored if the animal is kept in the dark. The green rays of light are those which are most effective in bleaching out its colour, corresponding to the fact that green light is most absorbed by a substance whose colour is a purplish red. In the human eye an intermediate stage in the bleaching out of this substance occurs in which it is yellow; and the presence in the retina of varying amounts of the visual purple and the visual yellow gives

rise to a succession of colours—purplish red, pure red, brick-red, orange, chamois, yellow. The regenerating purple does not go through the yellow stage. Regeneration takes place through the agency of the pigment epithelium; it goes on in the dark, even in the extirpated retina, so long as its outer surface is in contact with the pigment epithelium, and even if it has been removed and then laid on again. If a sharp image be thrown upon an eye in a state of darkness-adaptation, the eye being held immovable if the animal is alive, the light reflected from the bright portions of the object will cause its visual purple to fade out; images thus formed may be fixed and examined at leisure. They were called optograms by Kühne, who first prepared them. The visual purple cannot be seen in the ordinary eye, on account of the red colour of the background against which it is thrown; but there are a few fishes which have a white retinal tapetum, by means of the reflected light from which it is easy to see the colouring matter of the rods in its various different conditions (Abelsdorff). On looking into the eye of such an animal after it has been kept in the dark, the retina is seen to be first of a rose-red colour and then to change by gradual stages into a brilliant white. The relative absorption by the visual purple of the different radiations of the spectrum has been determined with great exactness by Professor König; he finds it to coincide with the subjective relative brightness-values of the totally colour-blind, and also with the relative brightness-values of the normal eye in a faint light. The coincidence of the curves representing these last two brightness-spectra had already been shown by Hering and Hillebrand (*Sitzber. Akad. Wiss. Wien*, 1889).

Other changes produced in the retina by light are the descent of the small black crystalline granules of the pigment epithelium into the spaces between the visual elements, and also variations in the resting electrical current between the surface of the retina and that of the optic nerve.

VI. COLOUR-THEORY: HISTORICAL. Ger. *Farbenlehre, Theorie der Wahrnehmung der Farben*; Fr. *théorie de la perception des couleurs*; Ital. *teoria della percezione dei colori*. The ancients were struck by the fact that coloured surfaces reflect less light than white ones, and hence they regarded the colours as made up by mixing black and white together (Aristotle). This was the prevailing theory up to rather recent times, and it was even defended by Goethe. The solution of the problem of colour in the physical sense is due to Newton; he proved that white light may be separated into light of different colours, that homogeneous spectral light does not have its colour further changed by a second reflection or absorption, that rays have different refrangibility, and that the colours of natural objects are due to the different ways in which they absorb and reflect different sorts of radiations. But Newton also was the first to lay down the fundamental principle of sensation in general, that it is of purely subjective character and has no necessary connection in kind with the physical cause that brings it forth. Newton says, 'The rays, to speak properly, are not coloured. In them is nothing else than a certain power or disposition to stir up a sensation of this or that colour. . . . So colours in the object are nothing but a disposition to reflect this or that sort of rays more copiously than the rest.' He supposed that the rays of light, 'by impinging on stiff refracting superficies, excite vibrations . . . of various bigness; . . . and therefore the ends of the capillamenta of the optic nerve, which pave or face the retina, being such refracting superficies, when the rays impinge upon them, they must then excite these vibrations, which vibrations . . . will run along the aqueous pores or crystalline pith of the capillamenta through the optic nerve into the sensorium.' It is difficult to imagine that there can be a sufficient number of optic filaments to respond in their vibration to all the different sorts of light (especially as difference in position upon the retina must be

the physiological correspondent of difference in spatial quality); this difficulty was met by Thomas Young with the hypothesis that all the colours may be simply combinations in various proportions of a certain number of elements—'each sensitive filament of the nerve may consist of three portions, one for each principal colour.' It was thus again a physicist and not a physiologist who added to our knowledge this important conception, that in the one-to-one correspondence between external nature and internal sensation (and even between external nature and physiological process) a series of continuous differences on the one hand can be pictured on the other by the union in a constantly varying proportion of a smaller number of constituents. But it was the physiological difficulty of imagining a sufficient number of tuned retinal fibres for all the rays of light, and not the deliverance of consciousness in regard to the unitary character of certain principal colours, that gave foundation for the constituent theory of light and colour. This accounts for the fact that three colours instead of four were considered to be a sufficient number of constituents (yellow was regarded as a mixture of red and green, although it is in no sense a reddish green or a greenish red), and no separate physiological process was assigned to the production of the totally different achromatic sensation, white or grey.

The physical facts of colour-mixture were of course known from the earliest times, and were brought into special prominence by the painters. Pliny states that the early Greek painters, who used only four pigments, succeeded in getting better effects with them than the painters of his time, who made use of a larger number. Nevertheless, the hypothesis of Young fell on unappreciative ears, but it was revived by Helmholtz in 1860, and has been the favourite view of the physicists ever since. The failure to recognize the fact, first made plain by Helmholtz, that mixtures of pigments are not the same thing as mixtures of colour (the former are a phenomenon of subtraction and not of addition) was the cause of much confusion and error. In his first experiments with spectral lights, Helmholtz could make grey only out of yellow and blue; this led Grassmann to a restatement of the fundamental principles of colour-mixture and of their graphical representation. A later series of experiments of Helmholtz by a better method removed the apparent contradictions. The principles of Newton's law of colour-

mixtures were also proved experimentally by Maxwell in 1857.

The theory of Young, in so far as it posits a small number of colour-constituents, is still the accepted theory, but in so far as it takes no account of the fact that yellow and white are simple sensations and not a psychological blending of two or more constituents, it has never made any appeal to the psychologist; we have in the purples an example of a sensation which *must* be a blend of several sensations, for there is no physical cause for their production except the combination of the causes of blue and of red; we therefore know the character of a colour-blend, and we know that white and yellow are sensations wholly destitute of this character.

Endless confusion has arisen on account of the extreme ambiguity that prevails in the terms used in connection with vision. *Light*, to begin with, is used indiscriminately for the light-sensation and for the photogenic radiations which are given off by bodies whose molecules are in a state of rapid vibration: it is impossible at present wholly to avoid this difficulty, but it would be desirable to use the terms *light-sensation* (*Lichtempfindung*) and *photogenic radiations* where the context renders the meaning at all obscure. So *colour* should be used in its subjective sense, and *xanthogenic*, *kyanogenic*, *chlorogenic*, and *erythrogenic radiations* should be substituted for the physical cause of colour.

But perhaps the worst confusion has occurred in speaking of the facts of what is called colour-mixture, when it is intended to designate the mixing of different rays or regions of the spectrum. For instance, 'orange' is sometimes a mixture of erythrogenic and chlorogenic radiations; it is not, however, psychologically, a mixture of red and green, but of red and yellow. Just as important, on the other hand, is the fact that perfectly homogenous photogenic rays of wave-length λ 492 are, psychologically, a bluish green or a greenish blue. Again, a certain *physical mixture* of orange and olive radiations will give a pure (but whitish) green, which as a colour sensation is not at all a mixture. To escape from this ambiguity it is absolutely necessary to employ distinctive terms. *Mixture* should be used for the physical procedure only. The various different psychological effects of light-ray mixtures may then be referred to as: (1) *colour-blends*, when the elements of the mixture are still perceptible in the result, as blue and green in the blue-

greens, or peacocks; (2) *colour-fusions* (or *colour-extinctions*), when the elements of the colour have disappeared in the process of mixing, as red and green in making yellow, and yellow and blue in making white. This is not the sense in which Külpe uses the term *fusion* for sensations in general, but it is indispensable to have the word for the results of colour-mixture. We should then say that the spectral yellow-green, when produced by homogeneous light, is not a colour-fusion, but a colour-blend, and that yellow when produced by red and green light is not a colour-blend, but a colour-fusion. (C.L.F.)

VII. VISUAL SENSATION, and LIGHT-SENSATION (with Colour-Theory): Ger. *Gesichtsempfindung*, *Licht- (und Farben-) empfindung*; Fr. *sensation visuelle*, *sensation de la lumière*; Ital. *sensazione visiva*, *sensazione di lume*. The term light-sensation is to be preferred, since it is better that the term 'visual sensation' should include the spatial element. For the foreign equivalents of *Colour-Theory* see above, VI. Visual sensations are of two very different kinds as regards quality—chromatic (the colours red, purple, yellow, &c.) and achromatic (the series white-grey-black). It is hard to find a good word for the latter series: (1) by an extension of its meaning (such an extension as is very natural to the mathematician) grey may be made to include the end members of the series black and white; in fact, Kirschmann has shown that when looked at through a tube, so that there is no opportunity for comparison with surrounding objects, there is no such thing as black and white; every achromatic surface is thought to be of some shade of grey; (2) Fick has called the sense which mediates colour the *specific* light-sense, and the other the *absolute* light-sense or plainly the light-sense—this latter term is in agreement with the universal usage of the ophthalmologists, and the phraseology is to be commended; (3) by Hering and his school the members of the achromatic series are spoken of as 'brightnesses.' Müller has shown that any given grey represents at once a definite quality (this is what was formerly not recognized) and a definite intensity, or stimulus energy. It is perfectly legitimate to speak of a given grey as a 'brightness' when regard is had to the voluminousness of the sensation, that is, to the subjective aspect of the *stimulus energy*; but to speak of its *quality* as a brightness is to introduce confusion, for it is impossible to give up the use of

the terms bright, dull, brightness, darkness, in the other sense, and in fact no effort is made to do so by writers who make use of this language. By the brightness of the most saturated yellow-green that we can produce, viz. that got by throwing yellow-green spectral light upon a portion of the retina which is already carrying a yellow-green after-image (even when Hering believed in the specific brightening and darkening powers of green and of yellow respectively he must have granted that there was a certain stage of the mixture where neither took place), Hering means the amount of the black-white constituent. But there is no reason for believing, in this case, that there is any black-white constituent present at all. It is, however, quite impossible for one who does not accept the theory of Hering to understand the meaning which he attaches to 'brightness'.¹ (C.L.F.)

Visual sensations are of two kinds: colours and brightnesses. The 'colours' are red, green, yellow, &c.; the 'brightnesses' are white, grey, black: the qualities of both series are equally simple.

(1) The brightness qualities fall between the limits of intensest white and deepest black. They form a one-dimensional manifold, and lie upon the axis of the tridimensional figure which represents the sum-total of visual sensations (colour sphere, double cone, double pyramid, &c.). They are probably the earliest type of visual sensation.

(2) Colours fall naturally into four series: red to yellow, yellow to green, green to blue, and blue to red. The four terminal colours of this series are named principal colours; the intermediaries, mixed colours.

An impression of 'colour' is fully characterized by the statement of (a) its colour tone or hue, (b) its brightness, and (c) its saturation. Colour tone is colour quality in the narrower sense—redness, blueness, &c. Saturation is the name given to the degree of distinctness with which a colour tone stands out from its attendant brightness quality; it expresses the 'distance' that separates the given colour from any quality of the brightness scale. Saturation is principally a function of the purity (homogeneity)

¹ The term 'brightness' is used in Hering's sense by E.B.T. It should be noted that the writers of this article, E.B.T. and C.L.F., are upholders of different theories of colour-vision, and their opinions are of necessity in some degree reflected in their respective contributions.—J.M.B.

of light; it is secondarily dependent upon intensity and wave-length. Colour brightness is the grey equivalent of the colour impression, the brightness quality which the impression would show were colour tone abstracted without alteration of stimulus energy. For any given wave-length and state of adaptation of the retina, it is dependent upon light intensity. König has compared the subjective distribution of brightness in the spectrum with the objective distribution of energy (Langley); he finds that a given amount of energy of ether-vibration is by far the most effective for the light-sense

saturation. Distance from the black-white axis indicates degree of saturation.

The number of discriminable brightness qualities is estimated by König at 660, by Külpe at 800; that of discriminable spectral qualities (conventional 'colour tones') by König at 160, by Külpe at 150. The estimation of 'mixed' colours varies, in recent books, from 40,000 to 'several hundred thousand.'

(1) We have spoken of the brightness of a visual sensation as a 'quality.' It is a peculiar characteristic of these sensations that change of stimulus intensity is corre-

Fig. 9. The relative brightness of the different parts of the spectrum for various different illuminations: from H, a strong light, to A, a very feeble light.

in the green, the maximum being at λ 505 (Helmholtz, *Festgruss*, 1891, 365). In Fig. 9 is shown the subjective distribution of brightness in the spectrum at various different illuminations: for a strong light the brightest part of the spectrum is in the yellow; when the light is so faint that colours are no longer discernible, it is in the green.

Colour tones may be represented upon the planes of longitude of the colour-sphere, cone, or pyramid; the purest tones are around the equator or base, the principal colours at the four corners in the case of the pyramid. The planes of latitude give surfaces of equal brightness, but of varying colour tone and

related always with change of brightness quality; so that the quality and intensity of a visual sensation are not independent variables. Visual sensations possess intensity; only, this must be termed 'intensity,' and not brightness ('intensity' of sensation being understood as that attribute of sensation whose continuous variation leads either to the point of complete disappearance—zero point—of the sensation, or in a direction precisely opposed to this, i. e. 'decrease' and 'increase' of intensity).

(2) The phrase 'primary colours' or 'fundamental colours' is of frequent occurrence. These colours differ, according as

they are fundamental for colour-mixture, for the art of painting, or for a particular theory of colour-vision. The psychological primaries—those which appeal to introspection as of cardinal importance—are the four 'principal' colours mentioned above.

There are two chief theories of visual sensation (cf. section VI of this article). (1) The first is the Helmholtz theory, based on the theory of Young. Every light stimulus sets up three distinct and elementary processes of retinal excitation, which in isolation correspond to the 'primary' sensations of red, green, and violet (or blue). The quality of a given impression depends upon the proportion of these partial excitations in the total excitation; the nearer the balance, the less saturated the colour—so that at equality we see simply grey light. This theory explains the facts of colour-mixture, which originally led to its formulation; it breaks down in face of the other facts of colour-vision. (a) So far from brightness sensations being dependent on colour, they persist after loss of colour: in indirect vision, in total colour-blindness, in extremes of illuminative intensity and duration. (b) Complementariness and its expression in partial colour-blindness can be explained on this theory only by the auxiliary (and highly improbable) hypothesis of a shift of the elementary excitabilities. (c) After-images cannot be explained as due to fatigue and recuperation; there is neither opportunity for recuperation, nor in daily life sign of fatigue. Visual fatigue must, therefore, carry its own corrective with it.

(2) The second theory is that of Hering. There are three visual substances, each liable to assimilative and dissimilative excitation. These substances furnish the six fundamental sensations: green and red, blue and yellow, black and white. The black-white substance is more easily excitable and more plentifully represented than the other two. Light of different wave-length affects the different substances differently (valence of stimulus). All light dissimilates the black-white substance; its assimilation comes from within. Dissimilation and assimilation in the same substance neutralize each other ('antagonistic' processes).

These assumptions explain the distribution of brightness in the spectrum, the facts of colour-mixture, complementariness, indirect vision, after-images, &c. Contrast and ADAPTATION (q. v.) offer no difficulty; they

are explained by reference to the excitability of the visual substances and the indirect effect of retinal stimulation. There is, however, a serious difficulty in the fact that we have a black-white sensation (grey), but no red-green or blue-yellow sensation. 'Antagonism' has two different meanings in the two contexts. The difficulty is removed by G. E. Müller's hypothesis that black and white are retinally antagonistic, and grey a cortical sensation. Müller has given the Hering theory a stricter and more elaborate formulation in other respects: e.g., as regards assimilation and dissimilation, the mechanism of retinal adaptation, &c.

Other notable contributions to visual theory are: (1) the molecular dissociation theory of Mrs. Ladd-Franklin; (2) the visual purple theory of Ebbinghaus; (3) the hypotheses added to the Young-Helmholtz theory by König; (4) the reconstitution of the Helmholtz theory by von Kries; (5) the periodicity or gradation theory of Wundt; (6) the hypotheses of Göller, Donders, &c. (E.B.T.)

The first demand to be made upon a colour-theory is that it should posit some (otherwise known) physical or physiological process to account for the most extraordinary fact of colour-vision, that on mixing physically certain colour pairs in certain proportions, the colours disappear, and a grey sensation takes their place; if this is not done, a theory is hardly deserving of the name. In the theories of Wundt and of Ebbinghaus there is no explanation given of this cardinal fact—complementary colour-processes are merely said to have 'something antagonistic' about them. The theory of Wundt, moreover, takes no account of the fundamental psychological fact of colour-vision, that we can distinguish between the intermediate elements of a colour-series which is constantly changing in the same direction—green, the blue-greens, the green-blues, blue—and the end members of such a series. The theory of Ebbinghaus is based upon views in regard to the nature of the pigment of the rods (the visual purple and the visual blue) which were rendered impossible by our knowledge of the function of that pigment as made out immediately after the theory was proposed. The theory of König is very different from the others. He believes that the cones have nothing to do directly with the luminous sensation, but that they are catoptric instruments for the purpose of condensing light upon the cells of the pigment epithelium, where the photo-chemical processes take place

which are the sources of the sensations of red, yellow, and green. The blue sensation is furnished exclusively by the visual yellow of the rods, and the sensation of a faint light (and that of the totally colour-blind) is also blue in quality, and is due to the visual purple; hence the fovea, where there is no visual purple, is blind to blue ('Ueber den menschlichen Sehpurpur und seine Bedeutung für das Sehen,' *Sitzber. Akad. Wiss. Berlin*, 1894). The blue-blindness of the fovea has not been confirmed by other observers; it is difficult to think that the cones can be condensing-glasses, and at the same time contain fibres of the optic nerve, but that they would have to do in order that the effect of photo-chemical processes taking place in the pigment epithelium might be communicated to the brain; rods and cones are so absolutely alike in structure (except for their basilar terminations, Plate I, Fig. 6) that it is unnatural to assign to them such unlike functions.

v. Kries is apparently in the anomalous position of believing that grey, when furnished by the cones, is a mental reconstitution out of the even red-green-blue sensations, but that, when furnished by the rods, it has its source in some distinctive physiological process.

Donders has a double theory—three-colour (with three different cones, to save the doctrine of specific energy) in the retina, and four-colour, with partial dissociation-processes, in the cortex. In his theory (as in Hering's) red and green are complementary colours, which is contrary to fact: green has for its complementary purple, and the complementary of red is peacock, or blue-green; red and green mixed together make, not white, but yellow. The followers of Hering are able to think of red and green as complementaries only by choosing a very bluish red (purple) or a very bluish green (a full blue-green in fact) as the elementary colours; but this is to give up at once the beautiful reliance upon our power to distinguish, by immediate introspection, between a 'mixed' and a 'non-mixed' colour, which it is Hering's great service to have brought about.

The theory of Göller is one of great interest on account of the fact that in it a conception has been devised by means of which the process which underlies colour may be regarded as an epiphenomenon, so to speak, i.e. as something superimposed upon an achromatic light-process; the theory makes use of the known highly refractive quality

of the end member of a visual element, and of the existence of a peculiar transparent thin plate just in front of it, to account for light becoming circularly polarized within the cones; the amount of disturbance corresponds then to degree of luminosity, and the plane of polarization to the colour. It is an impossible theory, because it requires us to suppose that molecular disturbances polarized in different planes can be propagated as such along the nerve-fibres; but the conception of colour as an *aspect* of a non-specific light sensation is not bad. It is, in fact, just what is needed by Hering to enable him to regard all the brightness of a colour as due to its black-white constituent, and as wholly uninfluenced by the presence of the colour-character (his idea of the specific brightening power of the colours was introduced to account for the Purkinje phenomenon, and is no longer necessary since that is known to be merely incidental to the oncoming of adaptation to a faint light: Tschermak); his own view, however, that chemical changes are going on in colour-substances which are of an exactly similar nature to those which take place in the black-white substance, and that they nevertheless contribute *nothing* to the total volume of the sensation, is very improbable.

The main objection to the theory of Thomas Young, an objection which is insuperable, and which lies upon the threshold, is that it takes no account of the fact, patent to the most cursory observation, that, while a mixture of the *causes* of red, green, and blue is sufficient to occasion the sensation grey, grey is nevertheless not a red-green-blue sensation. The theory is good, inasmuch as it reduces the innumerable physiological colour-processes supposed to exist in the visual organ by Newton to a small number: it accounts admirably, for instance, for the fact that all the successive homogeneous light-rays between $\lambda 505$ and $\lambda 470$ furnish *no new sense-quality*, but only a series of blue-greens gradually varying in the relative amount of each constituent sensation: this is just the sort of theory that the psychologist demands—the physiological conception offered mirrors correctly the deliverances of consciousness. And the same thing holds for the bluish-reds and the reddish-blues. But when we are asked to admit that in the third side of the colour-triangle the case is still the same, that what we call greenish-yellows and reddish-yellows are in reality, in this same sense, greenish-reds or reddish-greens, consciousness rebels;

and still more when we are required to think that, under whatever circumstances we sense grey, and even when we can get no *colour-sense* at all (e.g. in the wholly achromatic sensation of a faint light, and that of the totally colour-blind), we are really sensing red and green and blue without knowing it, and making, for no assignable reason, a totally different mental concept out of the congeries of colours felt together, the idea is so bizarre that it would seem as if to mention it were enough to show its inadequacy. The theory is a purely physical theory; so long as observers fastened their attention solely upon the *physics* of colour-mixing, it could play the rôle of a colour-sensation theory. For the physicist, the series, cold, less cold, indifferent, warm, hot, is also a continuous series, pictured in the gradual ascent of mercury in a thermometric tube; and so much did physics impose, until quite recently, upon psychology, that it required a distinct effort of discovery to establish the fact that heat is a sensation-*qualé* wholly distinct from cold (and, by way of sure confirmation of the fact, found to be communicated to the cortex by a distinct conduction-path).

What is meant by those who insist upon it that there are four (not three) unitary colour-sensations, and that all other hues besides those four are of the nature of colour-blends, is well set forth by G. E. Müller (*Zeitsch. f. Psychol.*, x and xiv) in a discussion of the different sorts of quality-series. It is evident that we are capable of distinguishing whether a sensation which goes through a series of changes before our eyes is changing *in a constant direction* or not. Thus if we look at a red revolving disk, and an assistant (without stopping the wheel) puts in constantly a greater and greater proportion of blue, the series of sensations which we get is a very different thing from what it is if he suddenly begins to add yellow—in the first case the series is varying in a constant sense or direction, in the other there is a sudden change in sense or direction. Now if we look through the whole circular gamut of colour-hues (the spectral colours completed by the lacking tones from red to blue) we find that it is not composed of a *single* series of this sort, but of several, interrupted by sharply marked points of breaking. As we approach the wave-length λ 505 on one side, the sensation is getting less and less yellow in character and more and more green (this is a variation of a constant sort), but the moment we pass that point there is a

distinct change in the character of the series—its successive elements get to look *less* and *less* like green, and more and more like something quite new, namely, blue. The colour-gamut, which is physically, like the tone-gamut, *rectilinear* (that is, consisting of a series of elements which differ one from another always in the same way, viz. by a constantly accelerating velocity of vibration), is, *for sensation*, not at all a rectilinear series (as is the series of subjective tones), but a series made up of several different stretches, with distinct inflections between them. This is not so well seen in the spectrum, where one of the stretches is partly wanting (the purples), and where differences in brightness are excessive; but if one takes a complete series of colour-hues in paper or in gelatine sheets (all equally bright and equally saturated), and arranges them upon the circumference of a circle, it will be impossible not to see that the series does not

Fig. 10. The psychological colour-square.

vary *in the same way* throughout the scale (as two tones have the same *sort* of difference between each other, viz. that of higher or lower pitch, no matter from what part of the scale they are taken), but that there are distinct *breaks* in the series. If such a series were to be represented in a diagram, that could not be fittingly done by a circle—a curve of constant curvature; we should have to use a figure with sharp angles in it, and, since the number of constituent stretches as well as the number of breaks is four, the proper figure is a square (Fig. 10). On one line of the colour-square, adjacent colours differ in respect to their relative blueness and redness; on another, with respect to their relative yellowness and greenness; it is as if, in one part of the tone-scale, two adjacent notes differed in respect of pitch, and in another part in respect of some other quality not the same as pitch. This is the way the colour-scale represented itself to the ancients, to Leonardo da Vinci, and to Goethe, and it was

only after Newton's discovery of the phenomena of colour-mixture that this fundamental property of the colour-series became completely lost sight of. The psychologists (those who study the exact deliverances of consciousness) owe a great debt of gratitude to Hering for having restored to introspection its proper importance; since his discussion of this question, it has been impossible for any one except a person who attends solely to the physics of light to accept a three-colour theory, or one in which white is regarded as a mental construction out of any number of colours.

It was pointed out distinctly by Leonardo da Vinci that the colours red, green, yellow, and blue differ *in kind* from such colours as orange, violet, &c. Their important character is evidenced by the antiquity of their names; these are so old, in many languages, as to have lost their original signification, while the intermediate hues, violet, orange, are still called by the plain names of the flower and the fruit which stand for them; and, strange to say, we have hardly got any (commonly accepted) names for the other intermediate colour-hues, blue-green and yellow-green. (They might appropriately be called peacock and olive; the latter in its ordinary sense is rather too dark and too greenish for the midway colour between green and yellow, but there is no harm in changing its signification a little for scientific purposes.)

The theory of Hering was accordingly a splendid advance upon the theory of Young; it formed a good resting-place in the history of colour-theory.

But, on the other hand, the theory of Hering fails to take sufficient account of the facts regarding the mixing of colour, in their present complexity¹. These facts are represented diagrammatically not only in the colour-curves, but also in the colour-triangle (Figs. 11, 14). The latter is a surface, and not, like the musical scale, a line (even a broken line is not sufficient), because it represents two modes of variation, hue and saturation (intensity may be represented also by extending the triangle into a solid body), and it is triangular because the assumption of three elements of mixture (or independent variables) is sufficient to produce all the colour-tones in nearly spectral purity. This is all that the colour-triangle represented in its original arbitrary form; the hypothetical colour-

elements could be placed at the vertices of the least enclosing triangle (Fig. 11), or at any other points that were, for any reason, desirable. Some writers even suppose, apparently, that nothing is represented in the colour-triangle except the complementarity of the colours at the opposite ends of a line. Much more than this is represented by the colour-triangle of König at the present-time.

For the mixing of colours, no method is of any scientific value in which there is not provision for the extremely accurate measuring of the wave-length and the intensity of several homogeneous constituents. By far the best method is that made use of in the (very expensive) colour-mixing apparatus of Helmholtz (made by Hänsch and Schmidt, Berlin: for description see the *Physiol. Optik*, p. 335). This is, in effect, a double spectroscope;

Fig. 11. The physical colour-triangle, with indication of the primary character of yellow and blue.

there are two collimator-tubes which throw light, after it has passed through a prism, into the two halves of a single telescope. The eye-piece of the telescope has been removed, and a plate carrying a narrow slit put in its place; the effect of this is that an eye looking through the telescope sees, not a narrow image of the collimator-slit, but the whole surface of the prism lighted up by homogeneous light. Each collimator-tube carries a double refracting prism of calcspar, so corrected by a prism of glass that each ray is undeviated in its course, and therefore still parallel with the axis of the tube. The two rays are the same as if they came from two images of the collimator-slit separated from each other by an amount depending upon the distance from it of the prism-pair; as that is changed, any ray of the spectrum can be brought into coincidence with any other, and since the rays are polarized in directions at right angles to each other, either ray can, by means of a Nicol prism also inserted in the

¹ For a good account of the physiological objections to the Hering theory, see Thomson in Norris and Oliver's *System of Diseases of the Eye*, i (1900).

tube, be modified in intensity at pleasure. The telescope faces symmetrically one edge of the main prism, and hence there is exhibited to the eye a field of view of conveniently large size, lighted up in the left-hand half by the combination of any two colours taken from the spectrum furnished by the right-hand collimator-tube, each present in any desired intensity, and in the right-hand half the same thing from the other collimator-tube, or, at pleasure, a single spectral colour, or white light. It will be seen at once that this apparatus offers facilities for making colour-mixtures with which no other method can be compared. (It is only from the laboratories of König and of v. Kries that investigations made with the aid of this apparatus have as yet issued¹.)

If one-half of the field of view of this apparatus is filled with a combination of two different lights, and the other half with a homogeneous light, or a different light mixture, or white light, and if the proportions and the character of the several constituents are varied until the two half-fields are indistinguishable, we are said to have before us a colour-equation. The colour-triangle is the diagrammatic record of the results of a vast number of such colour-equations. But it was only after the incorporation into it of the results of equations made by the colour-blind that it acquired its present importance.

It readily suggested itself that the different qualities of the sensation of light, being two-dimensional continua (abstraction being made of intensity), may be represented by the points of a plane. For the simpler forms of vision a smaller number of dimensions is sufficient. The totally colour-blind person has one sensation only (grey) in different degrees of brightness; a single point is sufficient for the representation of his sensation-scale. The partially colour-blind see two colours only, yellow and blue; these are for them the colours of the two halves of the solar spectrum; they are seen in full saturation up to wave-length $630\text{ }\mu\mu$ in the yellow, and beyond wave-length $475\text{ }\mu\mu$ in the blue. All spectrum effects

between these two points exhibit a constant variation in saturation up to white itself, and all such spectral effects can be matched by proper mixtures of the saturated end colours, yellow and blue. For these defectives, colour-mixture produces no new hue, but merely changes in saturation; their sensation-scale can be represented upon a straight line (Fig. 11a),

Fig. 11 a. (See the text.)

in which the co-ordinates of any point x will be 9:1 if the (unsaturated) colour which it represents can be got by mixing yellow and blue in the proportion one to nine, or white and blue in the proportion one to four, and this will serve to fix the position of the spectral colour which this mixture matches. (The wave-length which corresponds to the colourless sensation, W , is different for the two sorts of colour-defectives, protanopes and deutanopes; and it is also a little irregular on account of different amounts of absorbing matter in the yellow spot of the eye, if central vision is made use of.) There is another way of representing colour-quality diagrammatically, which runs parallel to this one, and in which the amounts of blue and yellow to be mixed are represented by the ordinates of two curves, the abscissae being the wave-lengths. The curves marked W_1 and W_2 in Fig. 12 b show the relative amounts of the two end-constituents which must be mixed together in order to match the continuous spectrum for each of these two classes of colour-defectives.

We come now to cases of normal vision. For such individuals it is not possible to match the whole series of spectral colours by means of the two end colours only. The ends of the spectrum are here, as before, for some distance, of unvarying hue, and differ in intensity only—the warm end up to $655\text{ }\mu\mu$ and the cold end beyond $430\text{ }\mu\mu$. Outside of these regions the spectral colours cannot be matched by the end colours, either alone or together, but it is necessary to take in a third constituent. This third constituent is in the first place chosen somewhat at hazard. (No single third constituent will give the spectral colours in full saturation, and hence a somewhat more saturated green than any in the spectrum is hypothetically taken as the third element of the sensation area.) With these arbitrarily chosen independent variables the

¹ For the production of somewhat nearly homogeneous light by means of gelatine plates, see Kirschmann, *Philos. Stud.*, vii. 543, and Hellpach, *Philos. Stud.*, xv. 527 (1900); for the liquids to be used for the same purpose, Nagel, 'Über farbige Strahlenfilter,' *Biol. Centralbl.*, 1899. Yellow cannot be got with gelatine plates, and for them must be substituted some fluid filter, e.g. one composed of a cell of potassium dichromate together with one of uranium sulphate.

colour-curves are laid down (Fig. 12 a): it is found that they do not coincide exactly with the curves of the two sorts of dichromates, the so-called red-blind and green-blind (Fig. 12 b). But would they have coincided if *different* independent variables had been chosen? The question is easily put to the test: it is a simple matter of mathematics (merely a

Fig. 12 a. The proportions of the three trial elementary colours required to match all the colours of the spectrum, for normal individuals.

Fig. 12 b. W_1 , K , curves of sensation for two green-blind; W_2 , K , those for two red-blind individuals; H , curve showing the intensity of the grey sensation for the totally colour-blind. (König.)

change in the triangle of reference) to find out if there are independent variables, that is, unit quantities of lights of particular wavelengths, such that the entire spectrum as seen by the three different classes of individuals can be built up out of like amounts of two or three of the several constituents. In fact, it was only necessary to substitute for the colours first chosen others mixed out of them in this way,

$$\mathfrak{R} = \frac{R - 0.15G + 0.1B}{0.95},$$

$$\mathfrak{G} = \frac{0.25B + G}{1.25},$$

$$\mathfrak{B} = B,$$

to find that, with these new constituents, the warm-end curve of one sort of defective coincided with the red curve, and that of

the other sort of defective with the green curve of the normal individual. In Fig. 12 a are represented the trial curves for König and Dieterici; in Fig. 13 the curves of coincidence for normal and semi-defective individuals. (In the dotted line of Fig. 12 a is given the green curve of a very small class of individuals, first noticed by Lord Rayleigh and by Donders, who differ markedly from the normal; they require, to make a given yellow out of red and green, four times as much red to a given amount of green as the normal individual does.) Expressed in other words, this is the same as saying that all colour-matches formed by normal individuals

Fig. 13. When λ 470 (blue), λ 505 (green), and a red a little less yellowish than the red of the spectrum are taken as the elementary colours, the colour-mixture curves of the normal individual become coincident respectively with those of the two sorts of partially colour-blind.

are recognized to be such by both sorts of dichromates¹, but that colour-matches formed by the protanope need to be distinctly changed before they are such for the deuteranope. This means that the colour-systems of both sorts of dichromates are reduction-systems—all their sensations are accounted for by supposing that one certain element (not the same for both) is absent in their case. This is a very important result. It has quite lately been fully confirmed by v. Kries ('Ueber Farbensysteme,' *Zeitsch. f. Psychol.*, xix, 1897). The theory of Hering fails to take account in any adequate way of the fact that the dichromates are of two different sorts, and that nevertheless their colour-systems are both simply reduction-systems of normal colour-vision. On the other hand, the Young-Helmholtz theory offers no explanation, of any degree of reasonableness, of the fact that the two classes of semi-defectives, instead of seeing red and blue, and green and blue, respec-

¹ The converse of this proposition is, of course, not true: countless things which look alike to the semi-defective are of different colour to the normal eye.

tively (if they had done this matters would have been very simple), see, as matter of fact, in both cases, *yellow* and blue. This is proved beyond question by the cases of unocular partial colour-blindness known since 1881; it was also perfectly well established, in 1874, by William Pole (the well-known authority on whist), by means of very acute observations upon himself, a semi-defective. Sir John Herschel, unconvinced by Pole, said, 'What the sensations of the colour-blind really are, we shall never know,' quite overlooking the possibility of cases arising in which the defect should be in one eye only. The theory of Helmholtz has imposed itself upon writers on this subject to such an extent that even now it is hard to convince them that these defectives are not 'green-blind' or 'red-blind'

Fig. 14. (For description see text.)

alone (they always neglect to mention what becomes of yellow). The report of the British Association Committee on colour-vision, so late as 1892, contains coloured spectrum plates showing the spectrum in green and blue and in red and blue, as it is supposed to be seen by these defectives, and Abney prefixes the same plate to his Tyndall Lectures on colour-vision published in 1894.

In its present form the colour-triangle constitutes a *vade mecum* for holding together for the eye a number of the facts of vision. (See Fig. 14.)

(a) Complementary colours are to be found at opposite ends of lines through the central point, *W*.

(b) The degree of whiteness of any non-

spectral colour corresponds to its nearness to the point *W*.

(c) Any non-spectral colour may be made up out of spectral lights situated at the ends of any line drawn through the point which represents it, mixed in the inverse proportion of the corresponding segments of the line, as indicated by the several lines drawn through *p* in the figure.

(d) The proportion of the 'elementary' constituents in any colour, spectral or not, may be got by dropping perpendiculars from its position upon the sides of the triangle; the perpendicular upon *BG* will give the amount of red, &c. (This is merely saying that we have here a representation of continuous quantities in terms of trilinear co-ordinates.)

(e) All the colours which for the normal individual lie on a straight line through *R*, as *Rr*, look exactly alike to the 'red-blind,' and are represented for him by the point in which that line cuts the line *Bg*. The reason for this is that the perpendiculars from any point of such a line *Rr* upon the two sides of the triangle, *RB* and *RG*, are in a constant ratio to each other; that is, points of such a line represent colours which contain the blue and the green elements in a constant proportion, and as they also contain no red, they are indistinguishable from each other. In particular, the point in which the line *Rr* cuts the curve of the spectral colours will give the wave-length which is represented at the point *r*. The same holds for the 'green-blind' and lines through *G*.

(f) It is commonly said in the textbooks that in the mixing of coloured lights 'the nearer the homogeneous lights are to one another the more vivid or more saturated is the intermediate colour' (Kölpe); this was a good first approximation to the true state of the case, and the colour surface was properly represented at first by a circle. But it is far from being correct. All spectral lights on either of the two nearly straight portions of the colour-curve can be matched, *with no loss of saturation*, by the lights at the ends of these stretches, although they are far apart. (This has lately been expressly reaffirmed by v. Kries.) On the other hand, colours taken from *different* stretches, when mixed, show rapid falling off in saturation. All this is plainly represented in the shape of the triangle: it is composed of two rectilinear stretches (λ 760 to λ 576 and λ 492 to λ 470) connected by a portion of rapid curvature.

The theory of Hering (which was first sketched out by Mach in 1865) is so vastly superior to the Young-Helmholtz theory, that until it has fully displaced that it is hardly desirable to discuss its demerits. Nothing is gained for the theory by saying that opposite colour-processes are due to assimilation and dissimilation of photochemical substances; the theory would be just as good (and less open to objection) if the nature of the antagonism in the chemical processes were left obscure—if they were said to have 'etwas antagonistisches' about them. There would then be no occasion for saying that the black and white processes have anything antagonistic about them; the sensations do not, as matter of fact, extinguish each other, like blue and yellow—they form a quality-blend, like blue and green; that is to say, the distinctive sensation-*qualé* of each does not disappear, they both remain in the constantly varying series of the greys.

Hering has done a great service in showing that a large number of the phenomena of vision are physiological, and not of the nature of mental errors, but it is too much the custom of his school to consider that a phenomenon has been explained by the theory when it has merely been translated into the terms of the theory. Thus when a patch of colour falls upon a bit of the retina, the sensation which it gives is accompanied by a sensation of the opposite colour-character furnished by the immediately adjoining portion of the retina. This Hering explains by saying that, if the original colour is caused by an assimilation process, the effect of this is to start up a dissimilation process in the adjoining region of the retina, and if it is a dissimilation process, it arouses an assimilation process there; but this is nothing more than to say (once it is admitted that the simultaneously induced colour is retinal) that one process of a colour pair has a tendency, in the interest of a restoration of retinal balance, to start up all around it the opposite process; nothing whatever is added to the intelligibility of the reaction by assuming that it is alternately assimilation and dissimilation. That is to say, there is no special *reasonableness*, derived from our knowledge of the nature of these processes elsewhere, in a patch of growth of a chemical substance in the retina becoming immediately surrounded by a region of decay, or in a patch of decay enclosing itself in a region of growth. It is none the less a matter of great importance that Hering

has shown by a large number of simple and ingenious experiments that the phenomena of the after-image and simultaneous light and colour induction are physiological in their character, and not of the nature of illusions of judgment. To take an instance: if, while a constant fixation-point is maintained, a number of different coloured objects be introduced at different times upon a common grey background, each will be seen to go through with its own series of after-effects and border-effects exactly as if the others were not present. So complicated a series of disjunct but simultaneous acts of judgment as would be involved in carrying out all these changes, different in period as well as in character, is quite inconceivable. There is no doubt that Helmholtz was wrong in attributing these colour and brightness effects to errors of judgment to the extent that he did; but it is also a great mistake to suppose that there is anything in an assimilation-dissimilation theory that is peculiarly fitted to explain them.

The objection to the Hering theory, that black and white are attached to antagonistic processes, is one that he could easily remove if he saw occasion for it; he would merely need to assume that those sensations are attached to photochemical processes in different substances, or that, for instance, white is retinal and black a mark of the resting-stage in the cortical portion of the total light-process. But the fact that it must regard red and green as a colour pair which, when combined, result in white, is fatal to his theory; it is the most elementary fact of colour-mixing that real red and green make yellow. Red and green are made a vanishing colour pair in this theory only by choosing as fundamental colours (*Grundfarben*) tones which are in fact distinctly blue-green and blue-red.

The two rival theories, therefore, are able both to continue to exist only by means of the fact that each is content to totally ignore the central facts of nature upon which the other is built up. The Helmholtz theory has no word to say to the fact that yellow, made up of red and green, is *yellow*, and not reddish-green, and that white is *white*, and not a reddish-greenish-blue. The Hering theory exists in complete oblivion of all the facts of colour-mixture—the facts which, in the laboratory of the physicist, are almost exclusively the ones that come within his ken. It is small wonder that the same dividing

line separates the adherents of the two theories and the adherents of the physical and of the physiologico-psychological sciences.

Again, neither of the two reigning theories pays any attention to the fact that the luminous function has probably undergone, like other functions of the body, progressive development¹. But the structure of the retina points already strongly to this view. It has lately been put beyond question (Ramon y Cajal) that the rods and cones represent not simply accidental variations in the shape of elements that are in reality of similar character, but that they are fundamentally different, and in fact that the cones (which, in an early stage of development, are exactly like the rods) are differentiated out of the rods in the direction of a higher structural development. It is not the cone shape that is their distinguishing mark, however—the closely pressed together cones of the fovea do not differ in shape from rods. In internal structure of their outer members (the falling apart into plates or disks), in their highly refractive character, in the possession of a fine covering-substance, in the presence of a thin plate between outer and inner member, the rods and the cones are exactly alike; but they differ markedly in the endings of the cell-fibre (see Fig. 6). The rods terminate in a minute expansion, or end-knob, which is grasped by the arborizations of the contiguous bipolar cells; the cones end in a more complicated structure—an expansion of finger-like processes which enter severally into connection with different bipolar processes. This distinctive structure appears late in the development of each cone, and is hence certainly late in phylogenetic development. It points to a provision for a less simple sort of excitation conduction than that of the rods. (It appears from this that the rods and cones have not been named from their most distinguishing characteristic—they should rather be thought of respectively as the *knob-end* and *finger-end* retinal elements.) The structure alone, therefore, of the visual organ is enough (since the brilliant anatomical researches of Ramon y Cajal have been accessible) to make it plain that we have in the visual sense an instance of progressive development.

But our knowledge of visual function leads conclusively to the same view. The visual process is not everywhere so complete as it

seems to us to be in everyday life, when we make use chiefly of the portion of the retina near the centre, and take peripheral stimulations merely as affording us a hint of what we are to look at next. If central vision is cut off, and we look at coloured surfaces with the extreme periphery of the eye, we perceive that their colour is no longer distinguishable—that all objects appear only in various shades of grey¹. As images fall upon retinal regions somewhat nearer the centre, yellows and blues begin to be perceived, but reds and greens are still seen only as greys, in as far as they are of purely fundamental tone; if they contain admixtures of blue or yellow light, this latter light is seen, but without any reddish or greenish tone. This zone of exclusive yellow-blue vision may be called the mid-periphery. (Its existence is affirmed by Hess, v. Kries, and others, and denied by Kirschmann.) Within this is the region of complete colour-vision, where all colours appear in their normal value. The boundaries of these regions would be somewhat differently laid down according to the size and the brightness of the test objects chosen, and to the time of their exposure².

These several capabilities of vision, according to the portion of the retina which mediates it, can only be regarded as different degrees of development of the sense of sight. Exactly corresponding to these retinal regions of the normal eye are the most frequent cases of

¹ Hellpach claims to have shown (*Philos. Stud.*, 1900) that in the ultra-extreme periphery, colour-vision is possible—that it is not there overlaid by the excessive white-contribution of the rods as it is just within. This would be, however, confirmation of the theory, for in that region there are cones in the retina, and no rods (Greef).

² The space-sense of the retina is also incomplete in this external region: a circle half white and half black on a grey background, if brought into the extreme edge of the field of view, can be seen to be composed of black and white when the relative position of the two half-circles cannot be at all distinguished. Also, a certain duration of exposure is essential to correct space-perception: if that is not sufficient, very different space-relations will be given from the actual ones (the physiological diffusion-circle: Exner, *Pflüger's Arch.*, 1898; Cattell, *Psychol. Rev.*, July, 1900). This is not strange, because it is a law of photochemistry that the amount of effect produced is proportioned not only to the intensity of the light, but also to its duration, and that intensity and duration can exactly replace each other (Ostwald). It is natural, therefore, that a stimulus which produces an insufficient amount of retinal excitation (whether from too short duration, too small extent, or too weak intensity) should fail to give sufficient material to the space-perceiving centres to enable them to work correctly.

¹ In the ear we have an organ for perceiving the sense-quality attached to difference of vibration-periods (pitch), and persisting side by side with it an organ for noise only.

defective colour-vision. Ordinary partial colour-blindness consists of vision for yellow and blue only (xanthokyanopia) and total lack of sensation for red and green. (It is still persistently said that these defectives 'fail to distinguish' red and green; they fail to *distinguish* them because they are totally blind to both; they see in their stead various more or less whitish yellows—see Norris and Oliver, *System of Diseases of the Eye*, Plate facing title-page. And though they are comparatively rare, the cases are perfectly well marked, and have now been thoroughly well examined, of those individuals who see no colour whatever—to whom the world is like a picture in various tones of grey.)

The molecular dissociation theory (theory of the differentiated chemical substances)¹ was devised with the intention of hitting upon a conception which should render intelligible both the facts of colour-mixture and all the psychological phenomena which the Hering school has done such good service in bringing to the fore, and which should at the same time take account of the probability which is now thrust upon us, that colour is phylogenetically a late acquisition—that the primitive sense was for the achromatic luminous quality only. If the retinal basis of the light-sense is a photochemical process (as is suggested by the known presence in the rods of a substance extremely sensitive to light), then this would mean that the eye which furnishes the colour-sense contains more complicated chemical substances than do the retinae which are defective—or, if the cones only furnish colour-sensations, that the cones contain more complicated chemical substances than the rods; at the same time the total effect of complementary colour pairs in the cones must be the same as in the rods, for we see whites in the fovea (where there are cones only) which are indistinguishable from the whites of the rods. It would be a difference of an adequate sort, therefore, if there were a chemical substance which in the cones underwent partial dissociation under the influence of light, and differently for the different regions of the spectrum, but which in the rods became completely dissociated at once, and alike for all sorts of light. It happens that there is immediate analogy for this conception of a photochemical substance which is, in primitive condition, dissociated at once, but, in more highly developed animals, dissociated in

successive stages: the rod-pigment, which exists first in the form of the visual purple, is turned at once into the visual white in animals below man; in man alone it passes through an intermediate stage, the visual yellow (Köttgen and Abelsdorff). A change of this sort, from a substance which is decomposed all at once (in the rods) to a substance which is decomposed in successive stages (in the cones), is just what it is sufficient to assume to account for the fact that from the rods we have colourless vision only, and from the cones distinction of colour, but such that there results, in the end, the same achromatic sensation in both¹.

Corresponding, therefore, to the successively developed powers of the retina for light-discriminations, this theory assumes a chemical substance which is, in the first instance, completely dissociated by light of all kinds (achromatic vision); then (owing to different synchronous intramolecular vibrations—in no other way can selective dissociation by light be conceived to take place: Ostwald) differently dissociated by the two halves of the spectrum (yellow-blue vision); and, finally, susceptible of partial dissociation in three different ways, but with the peculiarity that out of the products of the red and the green dissociation there is reconstituted at once the excitant of the sensation of yellow light². The actual molecule of such a photo-

¹ The existence of this analogy in the rods for a change in the character of a photochemical substance in the cones was not, however, known at the time this theory was proposed. The fact (for such it seems to be, although it has not been explained yet how other observers failed to notice it) was announced in 1895.

² The essential elements of this theory have been stated as follows by Dr. Bowditch: 'A colour-theory which is in some respects more in harmony with recent observations in the physiology of vision has been proposed by C. Ladd-Franklin. In this theory it is supposed that in its earlier periods of development, the eye is sensitive only to luminosity and not to colour—that is, it possesses only a white-black or (to use a single word) grey-perceiving substance, which is affected by all visible light-rays, but most powerfully by those lying near the middle of the spectrum. The sensation of grey is supposed to be dependent upon the chemical stimulation of the optic nerve terminations by some product of decomposition of this substance. In the course of development a portion of this grey visual substance becomes differentiated into three different substances, each of which is affected by rays of light corresponding to one of the three fundamental colours of the spectrum, viz. red, green, and blue. When a ray of light intermediate between two of the fundamental colours falls upon the retina, the visual substances corresponding to these two colours will be affected to a degree pro-

¹ *Zeitsch. f. Psychol.*, iv. 211 (1892).

chemical substance is certainly extremely complicated, but a molecule of complexity sufficient for the purposes of the theory is represented in the diagram (Fig. 15), which should be compared with Fig. 11 a.

portionate to the proximity of these two colours to that of the incident ray. Since this effect is exactly the same as that which is produced when the retina is acted upon simultaneously by light of two fundamental colours, we are incapable of distinguishing in sensation between an intermediate wave-length and a mixture in proper amount of two fundamental wave-lengths. When the retina is affected by two or more rays of such wave-lengths that all three of the colour visual substances are equally affected, the resulting decomposition will be the same as that produced by the stimulation of the grey visual substance out of which the colour visual substances were differentiated, and the corresponding visual sensation will therefore be that of grey or white. . . . The theory of Mrs. Franklin accounts for these phenomena [colour-blindness] in a still more satisfactory way; for, by supposing that the differentiation of the primary grey visual substance has first led to the formation of a blue and a yellow visual substance, and that the yellow substance has become in turn differentiated into a red and a green substance, colour-blindness is readily explained by supposing that this second differentiation has either not occurred at all or has taken place in an incomplete manner. It will be noticed that the important feature of this theory is that it provides for the independent existence of the grey visual substance, while at the same time the stimulation of this substance is made a necessary result of the mixture of certain colour sensations' (Bowditch, in *Howell's Textbook of Physiol.*, 1st ed., 1894, 784).

different circumstances, vision exists only for shades of grey—the field of view is like an engraving (but in three dimensions) in black and white; these cases are: that of total colour-blindness (congenital or from disease); that of the normal eye in the extreme periphery; and that of the normal eye when the illumination is very faint (night-vision).

The adherents of the Young-Helmholtz theory ignore the existence of white as anything except a product of the reconstructing mind, and hence, in spite of plenty of evidence to the contrary, the sensations of those individuals whom they named 'monochromatic' (in distinction from ordinary vision, which is tetrachromatic, but which was called, under the dominance of the colour-triangle, trichromatic) were dogmatically affirmed to be vision under the form of red or blue or green, it was uncertain which; and the colourless sensations of the periphery and of a faint light, although they are patent to observation, were wholly overlooked. Even so late as 1894 König affirmed that the vision of the faint-light 'monochromates' was in quality blue, in the face of the popular knowledge, 'im Dunkeln sind alle Katzen grau.' But as early as 1880 it had been put beyond question by Becker's case of monocular congenital total colour-blindness¹, that the sensation that remains is that of grey;

¹ *Arch. f. Ophthalm.*, xxv. (2), 205.

if the patient's vision is normal with one eye it is impossible to doubt that he can describe correctly what he sees with the other. Moreover, the numerous cases of acquired total colour-blindness, which there is no reason for putting wholly out of court, and especially those in which the defect comes on in one eye only, or in a circumscribed region of the retina (for instance, in tobacco and alcohol scotomata), had shown conclusively the same thing.

The quality of the sensation-series in all these cases is therefore grey—the different regions of the spectrum differ in luminosity only. Is the relative luminosity of the spectral regions the same as for central vision with the normal eye? In the case of the normal eye, estimations of brightness are difficult on account of the disturbing colour-differences, but by the method of the so-called flicker-photometry (see PHOTOMETRY, heterochrome) they can be made with great accuracy. In 1884 Donders, and in 1889 König and Dieterici, determined the distribution of brightness along the spectrum (what may be called the luminosity-spectrum, just as by absorption-spectrum is meant the relative amount of absorption in different spectral regions) for the totally colour-blind; it was found to be quite different from that for the normal eye, the maximum brightness being in the green instead of in the yellow.

A most important advance in this subject was made in 1889, when it was found by Hering and Hillebrand that the luminosity-spectrum¹ of the normal eye after the Purkinje phenomenon has set in (night-vision, darkness-adaptation) is exactly the same as that for the totally colour-blind at all illuminations², and at the same time, of course, very different from that of the normal eye in ordinary light. This is exhibited in Fig. 9 (where the scale on which the several curves are drawn is so chosen that green, λ 535, is taken as alike in all); there is a gradual falling off in the superior brightness of yellow until, at a certain low total luminosity, the maximum is in the green, and at this stage there is complete coincidence between the spectrum of the normal eye and that of the totally colour-blind. This made it look as if Hering's black-white 'valences' had indeed a separate

existence, and it spoke strongly against the theory of Helmholtz¹. It required Hering, however, whereas he had formerly maintained that colour has no effect upon brightness, to set up the theory of the 'specific brightening and darkening powers of the colours' (since given up: vide Tschermak). But the subject was soon afterwards put upon a very different footing by König; he showed that the (objective) absorption-spectrum of the visual purple (that is, the relative amounts of the light of different wave-lengths absorbed by it when it is extracted by gallic acid from a freshly enucleated human eye, and examined immediately, in a dark room, by means of a spectrophotometer) is also coincident with the (subjective) luminosity-spectrum of the totally colour-blind and with that of the normal eye in a faint light (which had been shown, as has just been said, by Hering to be coincident with each other). This forced upon one the conclusion that it was the visual purple that was involved in both of these two sorts of vision, and that that acted proportionately to the amount of light of any given kind that it absorbed. (This is not always the case in instances of photochemical dissociation by heat and light: Ostwald.) It was not shown by this that the visual purple was the photochemical substance of the rods—it might equally well act simply as an absorbent of an additional amount of light, which would otherwise go through the rods and be lost in the pigment epithelium and in the choroid. The fact that it is of a slightly different colour in fishes (and in fishes only), whose darkness is the darkness of ocean depths (and hence of a different colour from that of the depth of the forest), points to absorption as its essential function. Still less was it shown that the rods function in the darkness only, as v. Kries supposes; on the contrary, the *change* in the visual purple (regeneration in a faint light) is just what is needed to account for the *changed* values of night-vision. Again, it has been shown by v. Kries

¹ König admits that this coincidence made him, at first, 'ungemein betroffen,' but he goes on to say: 'aber zur Zeit der Epicyklen-Theorie hat man ja auch Sonnen- und Mondfinsternisse richtig im voraus berechnet' (*Helmholtz-Festschrift*, 354). This is a very acute remark. The ardent adherents of Hering are too much in the habit of protesting that every little coincidence furnishes a complete proof of the whole theory (Müller, *Zeitsch. f. Psychol.*, xiv). This particular one is not a little one, but what it proves is that white (grey) is a definite thing, alike under various circumstances—not that the Hering theory is true.

¹ It is desirable to use, for the time, the word luminosity in place of brightness, in order to avoid confusion with the meaning which Hering attaches to the latter word.

² 'Ueber d. spezifische Helligkeit d. Farben,' *Sitzber. Akad. Wiss. Wien*, 1889.

that the peripheral achromatic vision has a different distribution of brightness in the spectrum—the same, in fact, as that of the (heterochrome) brightness of the centre of the retina; this points to the fact, not that the cones alone function in the periphery (they are too few for that), but that the rod-vision, *when it is not reinforced by the visual purple*, is the same sort of thing, as regards its brightness-values, as vision with the cones.

It had been shown meantime (1892) that Newton's law of colour-mixtures (see X, below) did not hold at low intensities; its persistence under all circumstances had been affirmed by Maxwell, by Aubert, by v. Kries, and most vigorously by Hering. This fact had an important bearing upon the discussion.

In the remarkable case of congenital total colour-blindness of Raehlmann (*Arch. f. Augenh.*, ii, 1899), the distribution of brightness in the spectrum is quite unlike any other that has hitherto been observed: there was an extreme darkening in the part that is normally yellow, and blue was proportionally brighter than for the non-defective individual. But the abnormality in this case is clearly of cerebral origin, as is shown by the fact that foveal vision was retained.

IX. THE SEPARATE FUNCTION OF THE RODS AND THE CONES. Interest in the phenomena of visual sensation has centred of late years in the question of the discrimination of function of rods and cones, and in questions intimately connected with it. It would be singular if organs of such very distinctive structure (knob-like or finger-like connections with the bipolar cells, Fig. 6), and of such very different chemical contents (presence or absence of the rod-pigment), should not play a different rôle in the visual economy. Neither of these objective differences was known at the time when Max Schultze first made the suggestion that the rods constitute an organ for black and white vision only, and that colour is mediated only by the cones (1866); but there was already sufficient ground for his view in the fact that in the retina of many night-animals rods are found exclusively, or nearly so. This view seems to have been very generally overlooked (though it has been better kept in mind by the anatomists: Ramon y Cajal), until Parinaud revived it (1881), being led thereto by the study of hemeralopia (daylight vision—night-blindness), a disease in which the power of seeing things in a very faint light,

which the normal person acquires after remaining for twenty minutes or so in darkness (a power which may, correspondingly, be referred to as *night-vision*), is wholly wanting, and in which there is also degeneration of the pigment epithelium, which is known to be the source of the visual purple (rod-pigment). As he pointed out, animals which lack the rod-pigment altogether (doves, chickens) are also night-blind—'se couchent avec les poules.' But this night-vision, which would seem thus to be rod-pigment vision, is a form of achromatic vision—in an extremely faint light all colour disappears, and objects are seen only in shades of grey. Hence it seemed probable that the rods (at least, when they contain the visual purple) are organs for colourless vision only. (Parinaud regarded—and still regards—the vision of a faint light as due to the fluorescence of the visual purple; but that is impossible, for it is most fluorescent when it is in its completely bleached-out condition—the visual white.)

Other arguments were added by Parinaud. In the vision of approaching darkness-adaptation, differently coloured surfaces, before they wholly lose their colour, suffer a change of relative brightness (blues shine out brilliantly in a semi-darkness: the Purkinje phenomenon); but this change does *not* take place if the colours are looked at with the fovea only, and hence (since the fovea is lacking in nothing but rods) it must be a phenomenon dependent upon the rods, and in fact upon the regeneration of their visual purple¹.

¹ This fact—the absence of the change in brightness-values in the fovea (in other words, the failure of the Purkinje phenomenon)—has been warmly contested by several different observers, but the latest work of v. Kries on the subject (*Zeitsch. f. Psychol.*, xxiii, 183, 1900) puts it quite beyond question. He finds the unchanging region to be, for the dichromatic person tested (such individuals are far better adapted to tests of this kind than are others, because many combinations of objectively different spectral lights can be found which look alike to them in colour), for the horizontal direction $1^{\circ}47'$ in one eye and $1^{\circ}23'$ in the other, and for the vertical direction $1^{\circ}21'$ in both eyes. These dimensions are a little less than what Koster finds to be the diameter of the rodless region— 2° . But (1) there are, no doubt (as appears from these two eyes of a single person), great individual differences, and (2) a few scattered cones may well exist further in than Koster detected them. The amount of change was very slight until a definite remoter region was reached, and here it suddenly became much greater; this was, no doubt, about the place where the arrangement of one cone surrounded by a circle of rods is established.

It is still Parinaud who first pointed out that it is only the achromatic constituent of the sensation that is affected by this change. In proportion as the blues become relatively brighter, they become also less saturated, and, still more, the greens, as they become bright, become finally wholly uncoloured. The reinforcement occurs, that is to say, not for colour in itself, but only by way of mixing in more white or grey. (This is sufficient, doubtless, to account for the fact that in a very faint spectrum blue is not seen at all; the spectrum looks simply red or green, and this in spite of the fact that the Purkinje phenomenon is usually considered to consist exactly in the brightening of this colour. The blue becomes, in fact, so much overlaid with the white constituent furnished by the rods that it is no longer visible as blue.) Again, this fading out into an achromatic sensation before becoming wholly extinguished—which is what the Purkinje effect really consists in, the change in brightness being an attendant phenomenon—does not occur in the fovea. If a spot of coloured light is so minute as to throw its image upon the fovea only, then, however faint it is, if it is seen at all, it is seen in its true colour, not first by means of its colourless constituent. This has been doubted in the case of blue, but it has been confirmed by König and v. Kries, and recently again by Fick. (The case is less clear for yellow.)

The argument in favour of a difference in function of rods and cones was thus already in the hands of Parinaud exceedingly strong. It happened, however, that it remained completely overlooked, and the several facts noticed by him were rediscovered by other observers—the fact that colours seen with the fovea lack the preliminary achromatic stage of rod-vision by König in 1894 ('Ueber den menschlichen Sehpurpur, &c.', *Sitzber. Akad. Wiss. Berlin* vom 21. Juni 1894); König did not, however, uphold the theory here in question—he regarded the cones as catoptric instruments, viz. as condensers for throwing light upon the cells of the pigment epithelium, where he supposed all colour processes except that for blue to take place); the normal night-blindness of the fovea—that is, the fact that the extremely faint lights which the rod-adaptation exists for the sake of enabling us to see are wholly invisible in the fovea—and also the total blindness in the fovea of some of the congenitally totally colour-blind, a little earlier by Ladd-Franklin

(*ibid.*, 589, and *Proc. Amer. Psychol. Assoc.*, 1894); the absence in the fovea of any change in the relative brightness-values of different spectral lights, first made certain by v. Kries in 1900, by means of colour equations, in which each member is made alike in colour, although different in light-ray constitution (*Zeitsch. f. Psychol.*, xxiii). This theory of the probable difference in function of the rods and cones had already been made (1892) the ground-work of the molecular dissociation colour-theory (or theory of the developed photochemical substances: *Zeitsch. f. Psychol.*, iv, 1892); it is so strongly suggested by the fact that night-animals—owls, rats, moles—have retinæ almost wholly deficient in cones, but containing rods which are exceedingly rich in the visual purple, that it would have been simply accepted ever since its first proposal by Max Schultze had it not been that it was wholly contradictory to the reigning Young-Helmholtz colour-theory. v. Kries, who is a warm defender of the theory (but in the form that the rods are altogether a 'darkness-apparatus,' and that, although they outnumber the cones twenty to one, they are wholly functionless in an ordinary illumination), apparently holds now to the belief that there are two sorts of white—one physiological and brought about by a photochemical dissociation in the rods, the other psychical and due to a mental reconstitution of an even red-green-blue sensation into a sensation of indistinguishable quality from the first. From the laboratory of v. Kries have issued a number of important investigations which have had for their object the establishment of the disjunction of function of the rods and the cones; to refer to the theory as the v. Kries theory is, however, a mistake¹.

If the rods furnish colourless vision only, is it not possible that the vision of the totally colour-blind is vision solely by the rods? If that were the case, these defectives should be *totally blind* in the fovea, where there are only cones. That was found to be the case in the first instance of the defect which was tested in this regard (*Sitzber. Akad. Wiss. Berlin* vom 21. Juni 1894, 593). A number of cases which have been examined since (Hess, Hering, Pflüger) seem not to have had this defect; but the case of Uhthoff, which was first announced by him to be

¹ And still more so to call it (Abelsdorff) the Schultze-König theory. Aside from the question of priority, the theory of König is not even the same as that of Schultze, either for the cones or for the rods.

without it, has since been found, by more careful methods, to be actually an instance of total foveal blindness. But meantime there has been added to our knowledge of this subject the fact that a patient of Raehlmann's (*Zeitsch. f. Augenh.*, ii, 1899) had, with total colour-blindness, perfect visual acuity, which would not be possible without the functioning of the minute visual elements of the fovea. This case shows, doubtless, what was well known before from cases in which the defect is due to disease, that total colour-blindness may be caused by lesions or

Fig. 16. The persistence-values (the reciprocals of the brightness-values) of the normal eye: the 'green'-blind, and the 'red'-blind ----. (Ferry.)

malformations in the higher visual centres (though it is still not impossible that, in the instance of Frau Professor R., rods may have taken the place of cones in the fovea with no diminution of acuteness of sight). At all events, the fact that there are well-marked instances of foveal blindness in conjunction with total colour-blindness is conclusive of the non-existence of normally functioning cones in those cases in which it occurs.

The luminosity-spectrum of individuals affected with either of the two forms of red-green blindness has been obtained with much exactness by Ferry by the method of flicker-photometry. He finds that the persistence of

a colour-impression varies inversely with the luminosity, and is independent of the character of the colour. See Fig. 16.

X. NEWTON'S LAW OF COLOUR-MIXTURES.

This law states that if there are two pairs of indistinguishable light-mixtures, the double mixtures formed by uniting them two and two will also be indistinguishable; as a particular case, one pair of light-mixtures may be the same as the other pair, and hence the law covers the supposed constant equivalence of two like-appearing light-mixtures (whether coloured or colourless) under all variations of objective intensity of illumination. The case which is of especial interest on account of the bearing which it has had upon the theory of Hering is that in which a white (grey) is made, on the one hand, out of red and blue-green, and on the other out of blue and yellow, and the intensity of one or the other combination is diminished until the two are equally bright; if, now, the illumination for both mixtures be much reduced, do they continue to be of equal brightness? For an account of the history of this question see Tschermak, 'Ueber d. Bedeutung d. Lichtstärke u. d. Zustandes des Sehorgans für farblose optische Gleichungen,' *Pflüger's Arch.*, 70, 297. The law in its general form was tested experimentally and affirmed to be correct by Maxwell and by Aubert by means of the colour-wheel. v. Kries and Brauneck (1885) tested it by spectral lights, and again declared it to be valid. At the same time Hering published the results of his own investigation of the question, both by coloured papers and by a colour-mixing apparatus, and declared the 'complete constancy' of colourless and of

coloured equations under changing illumination. The next year, in his paper 'Ueber Newton's Gesetz der Farbenmischungen,' he reaffirmed this result in the strongest terms, and declared that any departure from Newton's law would be wholly inconsistent with the nature of things; he maintained in particular that such equations were not affected by the local condition of the retina, by fatigue, nor, in fact, by anything that could affect the temporary excitability of the eye. v. Kries also announced, in two papers of 1878 and 1882, that equations of all kinds persisted, no matter what the condition of the eye. Nevertheless, the law is now known not to hold: two whites of different light-ray constitution (red and blue-green as compared with yellow and blue) differ greatly in relative brightness, according as they are seen at a bright or a faint illumination (Ladd-Franklin, *Proc. Int. Cong. of Psychol.*, 1892; Ebbinghaus, *Zeitsch. f. Psychol.*, 1893).

The phenomenon is readily explained as a result of the regeneration of the visual purple, the connection of which with the supplementary vision of a faint light was affirmed in 1892, and put beyond question by König in 1894; this pigment is most effective for green light, and hence that member of the equation which contains green as one element of the mixture shines out brilliantly when the illumination is very much reduced. The exhibition of this phenomenon is now a common laboratory experiment. This worked strongly against the Hering theory as held at that time, but Hering has now admitted the fact of the departures from Newton's law, and also of their being due to the regeneration of the visual purple.

Zustandes des Sehorgans für farblose opt. Gleichungen, *Pflüger's Arch.*, lxx. 297 (1898); LADD-FRANKLIN, *Psychol. Rev.*, v. 309 (1898).

XI. THE AFTER-IMAGE. The phenomena of positive after-images (persistent retinal or nervous excitation) have been, of late years, very obscure, but the subject has been much cleared up by Munk (see RECURRENT VISION). One thing that is plain is that the achromatic and the colour constituent of the image (whether positive or negative) run a different course, and even that the red-green and the blue-yellow portions of a mixed sensation do not alternate synchronously (Walther,

Pflüger's Arch., 1898). Another thing that is quite certain is that the Helmholtz explanation of the negative after-image is wholly inadequate. It was first shown by Maria Bokowa (*Zeitsch. f. rat. Med.*, 3, xvii. 161, 1863) that the wearing of coloured glasses, if side-lights are wholly shut off, will bring about temporary colour-blindness. Coloured objects, if gazed at with absolutely constant fixation, become colourless; but they do more than that. There is one simple experiment, devised by Hering, which is alone enough to disprove at once the assumption of Helmholtz that the negative after-image is caused by a residual fraction of the self-light of the retina. If one stands in front of a window, in a bright light, and fixates for a while a patch of colour, say red, it is then only necessary to draw down a shade, or to go to a darker part of the room, to find that the patch, the eyes being still open and gazing at the red, has turned to a brilliant blue-green. This is quite incomprehensible on the view of Helmholtz; he would have us believe that although the eyes are open and gazing at red paper in light as intense as that of the ordinary room, nevertheless the self-light of the retina pushes itself so to the fore as to counterbalance, even in its semi-reduced condition (fatigue for red), an excitation which should normally be red. That, if the eye should look at white, fatigue for red would cause it to see only green is conceivable; but how can there be any sufficient cause for the production of green when the eye is looking at the most saturated attainable red?—for red, on the Helmholtz theory itself (*Physiol. Optik*, 370), contains no admixture of white. That the self-light of the retina is wholly inadequate to the production of after-images has been shown in detail, with spectral lights, by Hess, but this simple experiment is sufficient to prove it to any unprejudiced observer. There are only two ways in which this intense green-vision during the looking at red can be accounted for: (1) to suppose that after excessive chemical action of one kind nature quickly goes to work to perform the opposite process in amount proper to restore the balance (the opposite process theory), or else (2) that a chemical substance having been partially dissociated by red light, the unstable residuum becomes in turn destroyed, in the interest of the restoration of the retina to a *tabula rasa* for the reception of fresh impressions (the molecular dissociation theory).

Vision (defects of): Ger. *Gesichtsstörungen*; Fr. *troubles de la vision*; Ital. *disturbi della vista* (or *visione*). Vision may be defective as to any one of its three fundamental functions: as concerned with (1) light, (2) colour, (3) form, shape, distance (acuity), &c. As vision is possible in a considerable portion of the retina, any marked variation in the distribution of retinal sensibility would give rise to (4) defects of the visual field. A further characteristic of human vision is the co-ordination of the two eyes, which if defective gives rise to (5) a defect of binocular vision. Anatomically and physiologically, defects of vision would be classified according to the part of the eye or the nervous mechanism of vision that is affected. The class of defects thus outlined will also be noted.

(1) Defects of light-perception are present in all severe cases of BLINDNESS (q. v.); but so long as any power of vision remains some power to distinguish light from darkness is retained. Abnormalities in light-perception consist in a divergence from the normal conditions of illumination yielding clear vision. NIGHT-BLINDNESS (q. v.) and DAY-BLINDNESS (q. v.) are of this type. Variations in different individuals have been noticed as to the smallest visible light under given conditions, and as to the smallest distinguishable difference between illuminations; and these undoubtedly exceed in some cases what might be regarded as normal variations. As specific defects, however, they have not been described. Variations in the distribution of light-sensibility over different parts of the area, and the existence of the BLIND SPOT (q. v.), are also pertinent in this connection. On the general conditions of light-stimulation, see VISION I-V. See also BRIGHTNESS, and cf. OPTICS.

(2) Defects in colour-vision may be regarded as (a) COLOUR-BLINDNESS (q. v.; see also

VISION, VI ff.), and (b) subnormal and imperfect colour-vision.

(b) A diminished sensibility to colour-distinction is very common, and may be confused with colour-blindness. Moreover those slightly colour-blind (for the degree of colour-blindness varies greatly) may also have diminished facility in colour-distinction. This latter power is subject to education. The nature of the confusions concerned are not those characteristic of true colour-blindness, but appear as confusions of tints and shades, and of colours near together in the spectrum, or of mixed colours with similar components. The hesitation and slowness in matching colours in the tests for COLOUR-BLINDNESS (cited under that term) often reveal a poor colour-sense, although in the end the matchings are correctly made.

(3) If the inability to adjust the refractive mechanism of the eye is such that (for certain distances) the image is focussed at a point in front of the retina, MYOPIA (q. v.) occurs; if behind it, HYPERMETROPIA (q. v.). If there is a subnormal range of ACCOMMODATION (q. v.)—a condition incident to the growing inelasticity of the lens with age—there is PRESBYOPIA (q. v.). If the defect is such that vertical lines are not clearly seen at the same time with horizontal lines, there is ASTIGMATISM (q. v.). Such a defect may be due to irregularities in the cornea, in the shape of the eyeball, in the lens or in the muscles of accommodation. Total absence of the lens is termed APHAKIA (q. v.), and produces an excessive hypermetropia. The common method of expressing the acuity of vision is by means of the formula $V = \frac{d}{D}$, in which V expresses the acuteness of vision, d the distance at which the test-object is distinguished, D the normal distance at which such an object should be visible (the distance accepted is that at which it subtends an angle of five minutes at the fovea). Letters and various forms (the forms being preferred as less familiar and thus less apt to be guessed rather than read) are used of standard sizes and held at certain distances; the test with large letters at long distances yielding somewhat different results than small ones at short distances. If the numerator d is used to express in metres the distance at which the object is seen, and the denominator D the number of type on the test-board, then the fraction (e.g. $\frac{6}{12}$) tells not only that the subject has half the normal acuteness of

vision, but indicates how the test was arranged. There may be supernormal as well as subnormal visual acuteness. The two eyes may differ in their refractive powers, such difference being termed (when serious enough to be a defect) *ANISOMETROPIA* (q. v.); in such cases there is a strong tendency to use the more nearly normal eye in preference to both eyes. Another form of defect consists in an inability to maintain accommodation for a considerable period without excessive strain and fatigue; such a condition is termed *ASTHENOPIA* (q. v.). Defects in the perception of size, shape, and distance have not been specifically noted, apart from refractive errors and errors in binocular adjustment, except that in cases of slight detachment of the retina (when vision may be retained) the rods and cones preserve, at least for a time, their old local function, and objects looked at suffer corresponding distortions (*METAMORPHOSIA*, q. v.); Wundt, among others, has had, and has recovered from, this defect. It is of importance in connection with theories of *SPACE* (perception of, q. v.). In tests of the normal capacity in this respect, such as are customary in the psychological laboratory, considerable variations are found. Abnormal variations are usually dependent upon a general imperfection of vision or upon the defects just noted.

(4) The normal field of vision by the retina and the characters of vision in different parts of it are determined by the *PERIMETER* (q. v.). (See *INDIRECT VISION*.) Variations from the normal may occur in almost endless ways. Such restrictions of the retinal field are of great importance not only in practical diagnosis, but in the study of the nervous and cerebral substrata of vision. Of special interest is the condition termed *HEMIANOPIA* or *HEMIANOPSIA* (q. v.), in which a lateral half of each retina is affected. This usually points to a central nervous affection.

(5) Defects of binocular vision consist in a relative inability to command single vision with the two eyes; the double vision resulting from this defect is termed *DIPLOPIA* (q. v.). There may also be erroneous projection in the field of vision. The most frequent causes of binocular defect are over-strong action of certain of the ocular muscles, usually the internal rectus, or paralysis or weakness of one or other of the muscles in one eye. This condition, which is termed *STRABISMUS* (q. v.), varies considerably according to the particular muscles affected. A marked in-

equality between the two eyes in other respects is also likely to interfere with complete binocular vision, and to produce a greater dependence upon the perception of the normal eye. A binocular defect may also consist in an inability to maintain *CONVERGENCE* (q. v.) for a considerable time without excessive strain and fatigue; such a condition would be a form of *asthenopia*.

From the point of view of the location of the visual defect, abnormalities in the refractive parts of the eye have been sufficiently noted. The interest here pertinent in defects in the extra-ocular parts may centre in the muscles, which have also been considered; or in the fact that these muscles are represented both subcortically and cortically, lesions in the centres giving rise to paralysis and spasms of definite types (for the forms of muscular defect and their anatomical relations to the nervous centres see below, Norris and Oliver, *op. cit.*, and Gowers, *op. cit.*). Defects in the nervous mechanism may be in the retina, in the optic nerves, and in the lower or higher (subcortical and cortical) cerebral centres. Local diseases of the retina and optic nerve are mainly of ophthalmological interest (see the literature cited below). Affections of the optic tract, subcortical centres, cortical centres, and the connections between these have been studied with reference to the manner of connection of the retinal fields with the fibres and cells in this system. Although consensus as to detail is lacking in regard to the precise location of these centres, the subcortical centre is usually assigned to the corpora quadrig. anter., the corpora gernic. later., and the thalamus opt., and the cortical to the occipital lobe. Injury to these produces blindness in certain portions of the retinae according to the particular areas or fibres affected. The fact that each retina is connected with each hemisphere brings it about that injury to the centre (or tract) of one side produces half-blindness (*hemianopsia*) of each eye (see Fig. 7 under *VISION*). The varieties of *hemianopsia*, and particularly the retention or loss of vision in the central portion, the association of blindness in the upper and lower, nasal and temporal, halves of the two eyes indicate an extremely complicated scheme of connection. Injury to the occipital cortex may also produce mental blindness (see *BLINDNESS*, mental; cf. references given also under *HEMIANOPSIA*). Finally functional affections of vision of various types occur. *AMAUROSIS* (q. v.) and *AMBYOPIA*

(q. v.), occurring without recognizable ophthalmoscopic changes, are usually considered to be of this class. General anaemia, neuralgia, or neurasthenia, severe headaches, &c., may bring on temporary fogging of sight, localized anaesthesia (as hemianopsia), diminished colour-perception, subjective ocular appearances, and the like; while in HYSTERIA (q. v.) peculiar varieties of functional blindness occur. Subjective visual sensations are probably more frequent than those of any other sense, and appear as hallucinations in dreams, insanity, and other unusual nervous conditions (trance, hypnosis, &c.). See HALLUCINATIONS, and ILLUSIONS.

This article treats only of such defects and abnormalities of the processes concerned in vision as are instructive for the comprehension of normal vision. Diseases of the eye as such are not specifically included.

Literature: NORRIS and OLIVER's System of Diseases of the Eye (1897 and later); NOYES, Diseases of the Eye (1897); SWANZY, Diseases of the Eye (6th ed., 1897). See also the literature cited under the special topics referred to, notably VISION. (J.J.)

Vis maior [Lat.]: see ACT (in law).

Visual Area (measurement of): Ger. *Augenmass*; Fr. *estimation à vue d'œil*; Ital. *misurazioni ad occhio*. The name given to the comparison of distances in the plane field of vision by the unaided eye. Cf. EYE MOVEMENTS.

The relative sense-discrimination is constant (i. e. Weber's law holds) over a certain range of moderate distances, in the estimation of which the eye has had constant practice in everyday life. The threshold is approximately $\frac{1}{10}$.

Literature: the experimental investigations, of which there are a large number, begin with WEBER in Wagner's Handwörterb. d. Physiol., iii. 2 (1846), 558, and Ber. d. sächs. Soc. (1852), 85; HEGELMAYER in Vierordt's Arch., xi. (1859), 844; FECHNER, Elem. d. Psychophysik, i. 211, and Hauptpunkte d. Psychophysik, 338; VOLKMANN, Physiol. Unters. im Gebiete d. Optik (1863), i. 117; CHODIN in Arch. f. Ophthalm. (1877), xxiii. i. 92. See also WUNDT, Physiol. Psychol. (4th ed.), ii. 131; HELMHOLTZ, Physiol. Optik (2nd ed.), 740; VON KRIES, 'Helmholtz' Festschrift (1891); MÜNSTERBERG, Beitr. z. exper. Psychol., ii. 125; HIGIER, Philos. Stud. (1892), vii. 232. (E.B.T.)

Visual Axis: Ger. *Gesichtslinie*; Fr. *ligne visuelle*; Ital. *asse visuale*. A synonym

for the LINE OF VISION (q. v.) or line of sight.

It is not to be confused with the optical axis of the eye. (E.B.T.)

Visual Sensation: see VISION.

Visualization: Ger. (no single term); Fr. *visualisation*; Ital. *visione interna, endovisione* (suggested—E.M.) Mental imaging so far as it involves reproduction of visual experiences.

The most interesting point for the psychologist is the diversity of visualizing power in different individuals. Some are capable of calling up mental pictures scarcely, if at all, inferior in detailed distinctness of form, colour, and graduation brightness to the objects as actually seen by the bodily eye. On the other hand, there are some few who have scarcely a rudiment of visualizing power. Between these extremes a great number of intermediate stages are found. Cf. TYPE (mental).

Literature: GALTON, Inq. into Human Faculty; the literature of TYPE (mental).

(G.F.S., J.M.B.)

Vis viva [Lat.]: Ger. *Vis viva, lebendige Kraft* (not to be confused with *Lebenskraft*); Fr. *vis viva, force vive*; Ital. *forza viva*. Living force; the quantity represented by the product of the mass of a body into the square of its velocity.

It has nearly disappeared from current use as a physical quantity, being replaced by the term *energy*, which is one-half the *vis viva*.

The term arose from the fact that some effects of the power of a moving body were proportional to the simple velocity, and others to the square of the velocity. Thus arose the conception of *momentum*, proportional to the velocity, and *living force*, or *vis viva*, proportional to its square. (S.N.)

Vital Properties: see LIVING MATTER.

Vital Sensation: see ORGANIC SENSATION.

Vitalism: see LIFE, and cf. LIVING MATTER.

Vitality [Lat. *vita*, life]: Ger. (1) *Vitalität*, (2) *Lebenskraft*; Fr. (1) *vie*, (2) *vitalité*; Ital. (1) *vita*, (2) *vitalità*. (1) That which belongs to living organisms as constituting their LIFE (q. v.). Cf. VITALISM, and LIVING MATTER.

(2) Relative efficiency in the vital processes, (a) in degree with reference to a normal condition (as in the phrase 'impairment of vitality'), or (b) in endowment as compared with other individuals or species (as 'the vitality of an oak seed'). (J.M.B.)

Vitascope: see ILLUSIONS OF MOTION AND MOVEMENT, I, *Visual*.

Vividness [Lat. *vivere*, to live]: Ger. *Lebhaftigkeit*; Fr. *vivacité, intensité*; Ital. *vivezza, vivacità*. (1) Strength or intensive degree of an experience of any sort.

(2) By some considered a third original property of images additional to quality and intensity.

As a technical term the word has been employed to indicate a distinction between sensation with perception on the one hand, and idea on the other, the former being distinguished from the latter by greater vividness (Hume's distinction between 'impression' and 'idea,' *Treatise*, i. sect. 1, and iii. sect. 7). Thus the vividness attaching to direct experience of the external world becomes the test or sign of reality (Leibnitz), and so a criterion of belief (Volkmann). It is sometimes argued (Rabier) that relative vividness or intensity is the only distinction between perception and representation, and that artificial vividness attaching to memory or imagination may be the sufficient cause of illusion.

While undoubtedly true that vividness is primarily a property of sensory or direct experience, yet the psychophysical nature of it—described by the words strength, vivacity, vigour, liveliness, all used by Hume—is still obscure. Some hold that—like all intensity, or more certainly so—it is a qualitative distinction; others (recently Münsterberg) find in it an original property as in definition (2).

Literature: HUME, as cited; VOLKMANN, *Lehrb. d. Psychol.*, ii (with literary citations); RABIER, *Leçons d. Psychol.*; MÜNSTERBERG, *Grundzüge d. Psychol.*, i; the textbooks of psychology generally. (J.M.B., G.F.S.)

Vivisection [Lat. *vivus*, alive, + *sectio*, a cutting]: Ger. *Vivisection*; Fr. *vivisection*; Ital. *vivisezione*. Experimentation upon living organs or organisms in which vital processes form an essential element in the experiment.

The word has lost all trace (except in the minds of anti-vivisectionists) of its derivative meaning, dissecting alive, and is commonly used to designate all experiments, physiological, pathological, or anatomical, in which life, or vital process, of the animal or organ forms an essential part. (C.F.H.)

Vocal Cords (Ligaments or Bands) [Lat. *vocalis*, sounding]: Ger. *Stimmbänder*; Fr. *cordes vocales*; Ital. *corde vocali*. Membranes of the larynx concerned with voice production. See VOCAL ORGANS. (C.F.H.)

Vocal Organs: Ger. *Stimm-(Laut-)or-*

gane; Fr. *organes vocaux*; Ital. *organi vocali*. The apparatus for the production of sounds by the voice.

Nearly all air-breathing animals are provided with some sort of a vocal apparatus for recognition calls, warning cries, &c., and throughout the mammalian phylum the general plan of this mechanism is very similar in spite of great diversity in the character of the voice produced. The requirements of articulate speech in human beings have involved no important change in this general plan, but for the most part an increase merely in the range and delicacy of movement of the parts. This apparatus consists essentially of a pair of membranes or cushions (the so-called vocal cords) stretched across the trachea and supported by cartilages, to which are joined muscles connecting the cartilages to each other and to surrounding parts of the skeleton, so arranged as to vary the length, tension, and mass of the membranes and the position of the organ as a whole. Variations in the size and shape of the air columns above and below the vocal cords are also important factors in vocalization.

The lower Amphibia have only feebly developed laryngeal cartilages; but the frogs and other Anura have a well-developed voice box with vocal cords and the necessary muscles, so that these are the lowest animals which can properly be said to possess a voice. They illustrate also the important part played by the form of the air column set into vibration, for during vocalization a single or paired air-sac in the floor of the mouth is distended to form a powerful resonator. In birds there are two voice boxes, an upper and a lower. The upper corresponds to the larynx of other animals, but does not participate in vocalization. The lower voice box, or syrinx, lies at or near the union of the trachea and the bronchial tubes, where the cartilaginous rings of the trachea or bronchi are modified to form a resonance chamber within which are vibratile membranes which act like the vocal cords, and whose tension may be altered by appropriate muscles. The long trachea of birds serves as a resonator whose efficiency is in some cases greatly strengthened by further elongation produced by coiling the trachea upon or even within the sternum. In reptiles the larynx has moved upwards and, as in mammals, comes into relation with the hyoid bone. Some of the laryngeal cartilages have probably been derived phylogenetically from branchial, or visceral, arches of the

VOCAL ORGANS

gill-bearing vertebrates, as the hyoid bone is known to have been.

The human vocal organs have to produce changes in the loudness, pitch, and quality of tones. The first is accomplished by variations in the strength of the air-blast forced through the larynx, the second chiefly by changes in the length and tension of the vocal cords, and the third mainly by changes in the form of the resonance chamber between the vocal cords and the lips. The larynx, with its intrinsic and extrinsic muscles, and the entire cavity of the mouth, pharynx, and nose, with their contained organs, are therefore necessary parts of the organs of voice.

The larynx, or voice box, consists of nine cartilages bound together by movable articulations, enclosing the upper end of the trachea, which is here contracted to a narrow opening, the glottis, bounded by membranous folds, the vocal cords. Of these cartilages, six are in pairs and three are unpaired, viz. the thyroid, cricoid, and epiglottis. The cricoid forms the base of the larynx and completely encircles the upper end of the trachea. It has been compared to a signet ring with the seal on the dorsal side (see Fig. 1). The thyroid cartilage covers the ventral or front side of the larynx with two broad plates, or alae, extending dorsally and enclosing its sides. Each of those alae articulates with the cricoid at the side (Fig. 1), thus permitting a rocking motion between these cartilages on a transverse axis. The epiglottis is a leaf-like plate of cartilage attached by a slender stalk to the inner face of the thyroid cartilage in front, at the point of union of the alae. It is otherwise free and overhangs the upper opening of the larynx. Of the paired cartilages, the arytenoids are the most important. These are three-sided pyramids with their bases resting on the dorsal and highest part of the cricoid and their apexes approaching each other in the middle line dorsally of the opening of the glottis. The vocal cords extend from the arytenoids forwards to the inner face of the thyroid cartilage near the middle line (Fig. 2). The cornicula laryngis are articulated with the summits of the arytenoids, and the cuneiform cartilages are embedded in the mucous membranes just above the cornicula. They are frequently absent.

These cartilages are movably articulated with each other, and the intrinsic laryngeal muscles (seven on each side and one unpaired extending between the arytenoid cartilages) are so related to them as to cause a variety of

complex movements of rotation of the cartilages upon each other. By means of the intricate lever movements thus produced the positions of the vocal cords are varied in two ways, viz. (1) the width of the opening of the glottis between them may be changed, and (2) the length, thickness, and tension of the cords themselves may be changed. These two movements may take place independently of each other. The arrangement of the principal muscles involved may be gathered from Figs. 1, 2. The extrinsic laryngeal muscles may approximate the larynx and hyoid bone (thyro-hyoid muscle), or they may elevate the whole hyoideo-laryngeal apparatus (mm. genio-hyoideus, mylo-hyoideus, digastricus, stylo-hyoideus, hyoglossus), or they may depress the whole apparatus (mm. sterno-hyoideus, sterno-thyroideus, omo-hyoideus). They play an important part in varying the length of the air column in the production of tones of different pitch. The shape of this resonance chamber is also modified by all the other muscles of the pharynx and mouth.

Returning now to the larynx, it consists, as we have seen, essentially of the vocal cords, cartilaginous supports for these, and the muscles necessary for their regulation. The cavity of the larynx opens widely below into the windpipe; it is constricted in the middle by the vocal cords (Fig. 3), and again, higher up, by the ventricular bands or false vocal cords. Between these two pairs of membranous folds is a capacious dilation on each side, the ventricles of Morgagni, and above the ventricular bands the cavity again becomes very wide. This latter cavity communicates directly with the pharynx. It is overarched by the epiglottis, and this organ may be pressed down like a valve to shut off the cavity of the larynx from the pharynx. This is said to occur in the act of swallowing, though the sphincter muscles surrounding the superior laryngeal aperture are sufficient to effect the closure of this aperture without the aid of the epiglottis. The epiglottis probably has an important function in modifying the quality of the voice.

Much ingenuity has been expended to discover the true functions of the ventricular bands and the ventricles of Morgagni. The bands are well provided with mucous and serous glands, and the ventricles doubtless serve to contain this secretion and distribute it to the vocal cords. The bands, besides serving to protect the vocal cords from above, have also a valvular action, serving by

VOCAL ORGANS

Fig. 1. The larynx and its muscles as seen from the side, the right ala of the thyroid cartilage having been removed. From Gray's Anatomy.

Fig. 2. The interior of the larynx as seen from above, enlarged. From Gray's Anatomy.

Fig. 3. Vertical transverse section of the larynx. (After Testut, from the *American Textbook of Physiology*.) 1, posterior face of epiglottis; 1', its cushion; 2, aryteno-epiglottic fold; 3, ventricular band, or false vocal cord; 4, true vocal cord; 5, central fossa of Merkel; 6, ventricle of larynx; 6', its ascending pouch; 7, anterior portion of cricoid; 8, section of cricoid; 9, cut surface of thyroid; 10, thyro-hyoid membrane; 11, thyro-hyoid muscle; 12, aryteno-epiglottic muscle; 13, thyro-arytenoid muscle; 13', its inner division contained in the vocal cord; 14, crico-thyroid muscle; 15, subglottic portion of larynx; 16, cavity of the trachea.

VOCAL ORGANS

their apposition to close the air passage to outgoing currents, though they offer no obstruction to the inward current. As a matter of fact, the chief significance of the ventricles and ventricular bands is probably vestigial. In some apes the ventricles are enormously enlarged to form the 'vocal sacs,' which, when distended with air, may extend far down the neck and serve as powerful resonators (see Fig. 4).

In attempting to explain the practical working of the vocal organs in the production of speaking and singing tones observers have naturally turned to the various types of musical instruments for suggestive analogies. But it would appear that there is no single artificial instrument with which the vocal organs can be directly compared, and indeed the conclusions reached by those who have most exhaustively studied the vocal mechanism are so inharmonious that it cannot be asserted positively in what class or classes of instruments these organs should be placed.

The larynx is commonly described as a reed pipe with a membranous tongue. Helmholtz, in comparing the vocal cords with membranous reeds, says, 'They have the advantage over all artificially constructed tongues of allowing the width of their slit, their tension, and even their form to be altered at pleasure with extraordinary rapidity and certainty, at the same time that the resonant tube formed by the opening of the mouth admits of much variety of form, so that many more qualities of tone can be thus produced than on any instrument of artificial production.' The vocal cords, like membranous reeds in general, produce the sound, not by directly beating the air by the vibrating tongue, but by emitting the air from a narrow orifice in successive puffs like a siren. The vibratory pulses thus emitted are very complex, Helmholtz having demonstrated overtones up to the 16th partial, when one of the brighter vowels is sung by a deep bass voice.

According to the conception of Helmholtz, the quality of the voice is determined mainly in two ways: (1) by the form and tension of the vocal cords and their method of apposition, which will determine the number of upper partials in the tone as voiced in the larynx; and (2) by the form of the resonance chamber above the larynx, which will determine which one of these numerous partials will be reinforced. The quality of all musical sounds is dependent upon the relative force of the upper partials to the fundamental pitch,

and Helmholtz asserts that vowel qualities of tone are essentially distinguished from the tones of most other musical instruments by the fact that the loudness of their partial tones does not depend solely upon their numerical order as compared with their fundamentals, but preponderantly upon the absolute pitch of those partials.

The consonants are combinations of noises which have no definite pitch, and hence cannot readily be expressed in terms of musical notation. The physiology of their production is, however, more easily studied than is that of vowel sounds, and indeed lies at the basis of the conventional classifications of spoken sounds into labials, dentals, &c. For the details of the musical composition of the several vowels and the physiological movements necessary to produce them and the consonants, the reader must be referred to special works. It is obvious from what precedes that the act of vocalization is the most complicated and delicate of all the special muscular mechanisms.

The above is the classic explanation of vocalization as developed by Helmholtz. Very recently attention has been called to the fact that the vocal cords do not vibrate as elastic membranes, but as elastic cushions; i.e. they do not vibrate in the direction of the axis of the larynx, but at right angles to that direction. This conception, like that of the membranous tongue, considers that the air is liberated through the glottis in a succession of explosive puffs; but, unlike the former theory, does not regard the cushion itself, i.e. the lips of the glottis, as the source of the vibrations of the air column above. In accord with this, Scripture moreover decides, from a study of speech curves taken from a gramophone, that the movement of the air in the mouth cavity both in song and in speech is a free vibration and not a forced one, and

Fig. 5. Two diagrams of the vocal cords. (After Helmholtz.) The upper figure shows how the cords are brought together in firm contact and flattened forcibly against each other. The lower figure illustrates the way in which the air pressure in the trachea presses the cords apart.

that the characteristic mouth tones of vowels are generally inharmonic to the larynx tone, i. e. to the fundamental vibration of the vocal cords. In this he follows out the theory of vowel formation stated by Willis in 1830, rather than that of Wheatstone (1837), as modified by Helmholtz. The whole subject is one of extreme intricacy, and in view of the technical difficulties in the way of its study, it is not surprising that observers do not reach absolute agreement.

Literature: in addition to the general works on comparative anatomy and on human anatomy and physiology, reference may be made to the following: E. BEHNKE, *The Mechanism of the Human Voice* (1881); M. BELL, *Visible Speech* (1867); v. BEREZ-SZASZY, *Beitrag zur Anatomie und Physiologie des Kehlkopfs*, Arch. f. d. ges. Physiol., lxvi (1889); L. Phonetics* (1902); GARBINI, *Evoluzione della voce nell' infanzia* (1892). (H.H.)

Voice [Lat. *vox*, a voice]: Ger. *Stimme*; Fr. *voix*; Ital. *voce*. Sound uttered from the mouth; generally restricted to human sounds, while those uttered by animals are spoken of as cries. See VOCAL ORGANS, and cf. SPEECH. (C.F.H.)

Void: see VACUUM.

Volition: Ger. *Wollen*, *Volition*; Fr. *volition*; Ital. *atto di volontà*, *volizione*. The

settlement by the self of a psychic issue; the adoption of an END (q. v.). See also NOLITION.

Special cases are designated by the terms CHOICE, DECISION, RESOLUTION, FIAT, VETO (see those topics, also WILL). Volition is an END-STATE, in the more restricted sense applying to a conation; or a TERMINUS, when that again is restricted to the cognized object or END (see those terms).

The adjective volitional applies strictly to volition, and should replace the adjective voluntary, which is wider, applying to all acts or dispositions of will. See ACTION.

(J.M.B., G.F.S.)

Volitional (action, act, process, &c.) [Lat. *volitio*, act of willing, from *voluntas*, will]: Ger. *Willkür(-handlung, -vorgang, &c.)*; cf. TERMINOLOGY, German, 'Willens'; Fr. (*acte, &c.*) *de volition*, *volitionnel* (cf. VOLUNTARY); Ital. (*atto, &c.*) *volitivo*, or *di volizione* (cf. VOLUNTARY). Involving or issuing in a VOLITION (q. v.). Cf. ACTION.

Volitional acts are always voluntary and so always conative; but they constitute a species narrower than either of these.

(J.M.B., G.F.S.)

Volkman, Wilhelm Fridolin, Ritter von Volkmar. (1821-77.) Born and educated at Prague, where he became Privatdocent, and, later, professor of philosophy. A prominent Herbartian. See HERBARTIANISM.

Voltaire, François Marie Arouet de. (1694-1778.) Born at Paris and educated at the Jesuit college, Louis-le-Grand. Banished from Paris (1716) for some verses on the regent, he remained at Sully-sur-Loire until (1717) he was confined in the Bastille for a satire which he, by mistake, was thought to have written. Set free on condition that he went to England to live (1726). Returned in 1729; wandered about, writing industriously, until 1732, when he took up his abode with Mme du Châtelet at Cirey. After her death (1749) he went (1750) to the court of Frederick II of Prussia; but, exasperated and angry, fled 1753. After a few years of wandering, he purchased an estate near Geneva, which remained his home for some time and the resort of the literati of Europe. He was buried in the Pantheon, receiving absolution and a Christian burial by the Church. He was one of the ENCYCLOPEDISTS (q. v.).

Voluminousness. This word is employed by James as a synonym for EXTENSITY (q. v.) or extensiveness.

VOLUNTARISM

James' use of it (*Princ. of Psychol.*) is probably connected with the doctrine that extensity is 'three-dimensional.' This is suggested by the term voluminousness and not by 'extensity' or extensiveness.

(G.F.S., J.M.B.)

Voluntarism (in metaphysics) [Lat. *voluntas*, will]: Ger. *Voluntarismus*; Fr. *volontarisme*; Ital. *volontarismo*. The theory that the ultimate nature of reality is to be conceived as some form of will (or conation); contrasted with INTELLECTUALISM (q. v.).

The Greek mind was pre-eminently rational, and gave to experience an intellectual analysis and interpretation. The Romans and Hebrews both attached greater significance to personal will. Augustine gave expression to this in those parts of his system in which the will is made primary both in the individual and in the deity—'omnes nihil aliud quam voluntates sunt.' Consciousness itself as an act of attention is under the guidance and control of will, and God, as creator and saviour, shows his free will and 'grace.'

Mediaeval thought, which was influenced on the one hand by Greek rationalism and on the other by those motives in the Greek church which were drawn from both Hebrew and Roman sources, displayed intellectualism and voluntarism in clearly defined opposition. On the one hand, intellectualism was championed by Averroës, Thomas Aquinas, and the mystic Eckhart; on the other hand, voluntarism was defended by Avicenna, Duns Scotus, and William of Occam. The opposing theories were applied to the psychology of the individual, to the conception of the nature of the deity, to the field of ethics, and to the ideal of future blessedness. According to intellectualism, the choice of the will falls upon that which is recognized by the intellect as the good; according to voluntarism, it is the choice of the will which determines the object to be good. Each theory in this respect, therefore, was stating one side of what present psychology recognizes as the nature of value, i.e. as ultimately relative to personal choice, and not existing as such independently of such a personal choice (cf. WORTH). On the other hand, the intellectualist was seeking to maintain that, for the rational individual, value is not a matter to be decided by impulse or blind will, but is rather to be determined or, as intellectualism naturally states it, to be recognized by the reason.

On the question of the freedom of the will, intellectualism stood for determinism,

and voluntarism stood for indeterminism, and in reference to this opposition the remarks just made as to the relative truth of intellectualism and voluntarism will apply, with a slight change of phrase.

In the respective ideals of future blessedness, intellectualism, following the example of Aristotle, regards the state of final blessedness as a state of contemplation (*θεωπία*). Voluntarism maintains, on the other hand, that blessedness must be regarded as an activity, and finds this blessed activity in love, appealing to the text, 'The greatest of these is love.' Finally, these opposing theories lead to opposing views as to the nature of theology. According to intellectualism, theology should be an essentially speculative science; according to voluntarism, a practical science, controlling life, but not necessarily aiming to comprehend philosophic truth. This opposition, therefore, passes over readily into that between faith and reason.

In modern philosophy the great activity of scientific thought in the time of the Renaissance tended to emphasize the intellectualist categories for the interpretation of the individual and of ultimate reality. Descartes has an interesting blending of the two principles of intellectualism and voluntarism in his 'doctrine of error.' The intellect, if acting only under its own laws, attains truth, but when the will asserts itself prematurely by pronouncing a judgment, in cases where the intellect has not achieved complete clearness and distinctness, it gives rise to error and falsity.

In Spinoza the intellectualistic principle asserts itself as modifying and transforming the individualism which expresses itself so strongly in certain aspects of his thought. Desire is for Spinoza an indication of imperfection, and passions are a source of human bondage. When all things are seen purely in rational relations, desire is stilled, the mind is freed from the passions and experiences that 'intellectual love of God,' which is for Spinoza the ideal of blessedness.

Leibnitz conceived that Spinoza's interpretation of the world in rational and logical categories left no place for the individual, or for the conception of ends or purposes as a determining factor in reality. In his own conception of the universe, Leibnitz attempted to adjust the claims of intellectualism and voluntarism; e.g. in the theory of knowledge he distinguished between the *vérités éternelles*, which conform to the laws of rational or

logical necessity, and the *vérités des faits*, which conform to the principle of sufficient reason, and this is defined more particularly as a 'choice of the best' on the part of the deity. In the metaphysics of his system voluntarism again asserts itself in his views of the monads, or individual units of which all reality is composed, for the laws of these monads are conceived to be the laws of the conscious realization of ends, while the means employed for the attainment of these ideal ends must conform to the laws of rational necessity.

More recent voluntarism owes its origin to Kant, and particularly to his doctrine of the 'primacy of the practical over the pure reason.' Intellectually, man is incapable of knowing ultimate reality, but this need not and must not interfere with the duty of acting as though the spiritual character of this reality were certain. Freedom cannot be demonstrated speculatively, but whenever man acts under a motive supplied by reason, he is thereby exhibiting the practical efficiency of reason, and thus showing its reality in a practical sense.

Following Kant, two distinct lines of voluntarism have proceeded, which have had increasing influence during the past (19th) century. These may be called respectively rational and irrational voluntarism, whose originators were respectively Fichte and Schopenhauer. Fichte starts more directly from the Kantian position, but draws the issue more sharply. Not only does Fichte make the ethical primary in the sphere of conduct, it is for him primary even in the sphere of knowledge. The whole nature of consciousness can be understood only from the point of view of ends which are set up by the self. The actual world, with all the activity that it has, is only to be understood as material for the activity of the practical reason, as the means through which the will achieves complete freedom and complete moral realization. The writers who have developed voluntarism, with greater or less reference to Fichte's principles, are Beneke, Fortlage, Wundt, Maine de Biran, Renouvier, and William James.

Schopenhauer's voluntarism asserts a more radical opposition between the will and intellect than that represented by the Fichtean line. For him, the will is by its very nature irrational. It manifests itself in various stages in the world of nature as physical, chemical, magnetic, and vital force, pre-emi-

nently, however, in the animal kingdom in the form of 'the will to live,' which means the tendency to assert itself in the struggle for means of existence and for reproduction of the species. This activity is all of it blind, so far as the individual agent is concerned, although the power and existence of the will are thereby asserted continually. Schopenhauer attaches his system to that of Kant by the claim that the world, as conceived under the 'forms' of space and time and the 'categories' of the understanding (which Schopenhauer reduces to one, viz. cause and effect), is merely a world of presentation (*Vorstellung*)—it may even be called a world of illusion (*Maya*). The true nature of reality, on the other hand, or what Kant spoke of as the 'Thing-in-itself,' is not to be reached through the intellect, but through the immediate consciousness of the will. The world is, as it were, experienced from the inside, under the form of will, whereas through our intellectual interpretation we apprehend it merely from the outside. Intellect and will are frequently at cross purposes, but in comparison with the will, which is the real driving force or ultimate principle, the intellect is to be regarded as merely an excrescence which the will has assumed in man. The theory of voluntarism is in Schopenhauer combined with pessimism (q. v. under *OPTIMISM AND PESSIMISM*), which declares the activity of the will to be essentially a painful activity, since desire, the typical assertion of the will, always presupposes want. Release from this ever unsatisfied craving of the will may, according to Schopenhauer, be found in two ways. A temporary release is found in the aesthetic contemplation of the work of art. Here desire is stilled (cf. Plato's view of *BEAUTY*, q. v.). Complete release is found only in a denial of the will to live, and this, Schopenhauer maintains, is the fundamental principle of Buddhism and Christianity. v. Hartmann has developed Schopenhauer's principles in his philosophy of the *UNCONSCIOUS* (q. v.). Certain sides of the philosophy of Nietzsche represent the principle of voluntarism in its irrational form. In general, it may be said that voluntarism has been a growing tendency in recent thought.

Literature: PAULSEN, *Introd. to Philos.* (1895), 111 ff.; KÜLPE, *Introd. to Philos.* (1897); CALDWELL, *Schopenhauer's System in its Philosophical Significance* (1896); EUCKEN, *Einheit des Geisteslebens* (containing criticism of Intellectualism, 1888); LADD, *A Theory*

of Reality (1899, index, 'Will'); WUNDT, Syst. d. Philos. (1889), 373 ff.; JAMES, The Will to Believe (1897); MÜNSTERBERG, Philos. and Life. (J.H.T.)

Voluntary (action, act, process, &c.) [Lat. *voluntas*, will]: Ger. *Willens(-handlung, -vorgang, &c.)*; cf. TERMINOLOGY, German, 'Willens'; Fr. *volontaire*; Ital. *volontario*. Conative, i.e. involving CONATION (q.v.).

Voluntary processes may or may not be VOLITIONAL (q.v.) processes (cf. the scheme of terminology given under ACTION). They therefore include both those acts which we actively will (volitions), and those with reference to which we are merely 'willing.' Unrestrained impulses are voluntary even when acted upon spontaneously.

Voluntary processes are contrasted with non-voluntary (aconative) on the one hand, and involuntary (contra-conative) on the other. (J.M.B., G.F.S.)

Voodoo [Creole Fr. *vaudou*, a negro sorcerer; possibly a form of *Vaudois*, a Waldensian, these as heretics having been accused of sorcery]: Ger. *Voodoo*; Fr. *vaudou*; Ital. *vudu*. Voodoo is a special form of sympathetic magic, partially of African origin, and current mainly among the negroes and creoles of the southern parts of the United States.

The nature of the process is generally the same as that of magic elsewhere, and takes the form of malicious and noxious charms

and rites, healing and soothsaying formulas, witchcraft and omens. See MAGIC.

There is some tendency to use the word in a general sense for evil influence or ill fortune supposed to be effected by mysterious means. (J.J.)

Vulgate [Lat. *vulgata*, from *vulgare*, to make common]: Ger. *Vulgata*; Fr. *Vulgate*; Ital. *Vulgata*. The name of Latin translations of the Bible, applied first to certain African versions made from the LXX, during the 2nd century, and more especially to the Latin version of St. Jerome made at Rome at the close of the 4th century by comparison with the original Hebrew and Greek.

St. Jerome undertook the work of revision at the request of Pope Damasius, and brought to his work a knowledge of Greek and of Hebrew, which he studied for the purpose. His work received the official sanction of the Roman Church. At the invention of printing, the *Vulgate* was the first book produced from movable types. It is the basis of the Wickliffe translation into English, and through it has exercised an important influence on the development of the English language.

W

WAGE-FUND THEORY — WALLER'S LAW

Wage-fund Theory: Ger. *Lohnfondstheorie*; Fr. (no recognized equivalent); Ital. *teoria del fondo-salario*. The doctrine that wages depend on a ratio between population and capital.

The popular theory of wages is that they depend on demand for commodities; that the expenditure of the rich is a source of prosperity to the labourer. The English economists, from Ricardo to Mill, showed the error of this view, and proved that it is not the wealth which the capitalist consumes that really goes to the support of the labourer, but the wealth which he does not consume. These economists made the savings of the capitalists the source of demand for labour, and said that these accumulated savings or capital constituted a wage-fund, which determined the amount of real wages. Long, Thornton, Walker, and others demonstrated the practical error of this view by showing that wages often were high when the wage-fund theory would have them low, and vice versa; but the theoretical fallacy was first pointed out by Newcomb, who showed that a quantity of capital divided by a number of people cannot possibly give a rate of wages. In other words, wages are a flow, and not a fund.

Literature: WALKER, *The Wages Question*; TAUSSIG, *Wages and Capital*. (A.T.H.)

Wages [AS. *vadis*, a pledge]: Ger. *Arbeitslohn*; Fr. *salaire*; Ital. *salario*. (1) The remuneration of labour as distinct from that of other factors in production.

(2) The sums paid by property owners or their representatives to labourers for work done under the direction of the property owners.

If the degree of education required be such that the labourers must be in large measure self-directing, these payments are known as

salaries or *fees*; the former corresponding to time wages, the latter to piece wages.

If we treat problems of wealth and distribution from the public standpoint, the first of these definitions is the logical one. If we treat them from the private standpoint, the second definition is much to be preferred. In fact, the first definition is a dangerous one, owing to the extreme difficulty of separating wages as thus defined from any other class of income whatsoever.

Literature: CANNAN, *Hist. of Theories of Production and Distribution*. (A.T.H.)

Wagner, Rudolf. (1805-64.) Educated at Erlangen, Würzburg (in comparative anatomy under Cuvier), and Paris. Professor of zoology at Erlangen, 1833; in Göttingen 1840, where he died. His works were influential in the sphere of physiological psychology.

Waitz, Theodor. (1821-84.) Born at Gotha, he studied at Leipzig and Jena, and travelled in France and Italy. Professor of philosophy at Marburg after 1864, and devoted during his later life to anthropological psychology. See HERBARTIANISM.

Wakefulness: see INSOMNIA.

Wallace, William. (1843-97.) Born at Cupar in Fife, Scotland; educated at St. Andrews and Balliol. He was fellow and tutor of Merton College, and succeeded T. H. Green as Whyte's Professor of Moral Philosophy at Oxford, 1882. He delivered the Gifford Lectures in 1894-5. A leader of the English Hegelian school. He translated and commented on certain of Hegel's works.

Waller's Law: Ger. *Waller'sches Gesetz*; Fr. *loi de Waller* (more commonly, *méthode, ou dégénérescence, Wallerienne*—Y.D.); Ital. *legge di Waller, or legge Walleriana*. The empirical rule that after section or injury to

a peripheral nerve the degenerative changes pursue a direction similar to that normally followed by the stimuli.

In 1850 it was observed that after section of a peripheral nerve the portion beyond the injury degenerates. The axis cylinder and medullary sheath decompose, and the nuclei at first proliferate and then, in event of failure to re-effect central connection, disappear. Waller explained these facts by assuming that the central system exerts a trophic influence which is abolished by section. In 1868 Vulpian published the results of a study of the spinal cord of persons who had suffered amputations. He found the cord reduced in size in the half corresponding to the limb amputated, but the changes were regarded as atrophic. Friedlander and Krause showed that these changes are limited to the centripetal system (dorsal and lateral columns, Clarke's columns, &c.), while the ventral root is unaltered (see SPINAL CORD). Although many subsequent observers report changes in the ventral roots and cells of ventral cornua, they are now known to obey a different law from the degenerations of sensory fibres. They originate in the cell and follow the same course as that normal to the stimulus (Bregmann). The applicability of Waller's law is not discredited by degenerations of disease in motor roots, for, as already noted, they too follow the direction of the stimulus and suggest a trophic influence on the part of the cell. See DEGENERATION. (H.H.)

Want: see NEED.

Wants [*Icel. vant, wanting*]: Ger. *Bedürfnisse*; Fr. *besoins*; Ital. *bisogni*. (1) Those desires which give rise to a demand for wealth.

(2) The direction taken by such demand.

Want, in the second sense, differs from demand in not being a quantitative expression. We may say that the quantity of a want which a man will satisfy under given conditions represents his demand under those conditions. (A.T.H.)

War [O.H.G. *werra*]: Ger. *Krieg*; Fr. *guerre*; Ital. *guerra*. A state of hostility, looking to or being a conflict of arms between nations, or (civil war) between a nation and a considerable part of its citizens.

Within the meaning of the provision against treason in the United States Constitution, war is levied 'if a body of men be actually assembled for the purpose of effecting by force a treasonable purpose' (*Ex parte Bollman*, 4 Crench's U. S. Law Reports, 75).

War may exist, in fact, before it has been

formally declared. It makes all commercial intercourse between subjects of the belligerent powers unlawful, and suspends the right of action on their prior contracts until after the close of the war (Woolsey, *International Law*, § 117). *Articles of war*: the rules adopted in any state for the regulation of the army. Those of the United States are in the U. S. Revised Statutes, sec. 1342. See BELLIGERENCY, and NEUTRALITY.

The law of war was largely put in form by Grotius, in his *De Jure Belli ac Pacis*. (S.E.B.)

Warm Spot: see TEMPERATURE SPOT, and TEMPERATURE SENSATION.

Warning Colours: Ger. *Schutzfarben* (protective colouring); Fr. *couleurs protectrices* (protective colouring); Ital. *colori ammonitóri* (suggested—E.M.). The conspicuous colours of certain organisms, especially insects, associated with noxious or nauseous qualities, or perhaps in some cases with excessive hardness or toughness, of which they give 'warning' to other creatures. (C.L.L.M.—J.M.B.)

The origin and value of warning colours have been considered by biologists in close connection with biological MIMICRY (q.v.). On the selection hypothesis they have been evolved in close association with noxious or nauseous qualities in organisms, and are due to conscious but not purposive selection (see SELECTION). Only in virtue of what in psychological analysis is termed association can they possess any value. If, as recent observations seem to show, the young animal learns by experience what is to be avoided for the future, warning colours serve as a means to render this learning more rapid and certain. In Poulton's classification of animal colours they are termed *aposematic*. When, in accordance with Fritz Müller's suggestion, different distasteful species have common warning colours, the term *synaposematic* is applied by Poulton. See MIMICRY (in biology).

Literature: A. R. WALLACE, *Proc. Entomol. Soc.*, ser. 3, v. p. lxxx (1867); and Darwinism; J. JENNER WEIR, *Trans. Entomol. Soc.*, 1869; A. G. BUTLER, *Trans. Entomol. Soc.*, 1869; A. WEISMANN, *Studies in the Theory of Descent* (Eng. trans., 1882); E. B. POULTON, *Proc. Zool. Soc.*, 1887, 191, Pt. II. 336-40; and literature cited under MIMICRY (in biology). (C.L.L.M., E.B.P.)

Wealth [AS. *wela*, plenty]: Ger. *Wohlstand*; Fr. *richesse*; Ital. *ricchezza*. (1) An aggregate of commodities.

(2) The value of such an aggregate, measured

by the quantity of money, or some other commodity, for which it can be exchanged.

The mercantilists laid stress on money values, the physiocrats on food values. Smith nowhere defines wealth; McCulloch defines it: 'Those articles which possess exchangeable value, and are either necessary, useful, or agreeable.' Malthus is the first prominent writer to leave the feature of valuation on one side: 'The material objects, necessary, useful, or agreeable to man, which have required some portion of human exertion to appropriate or produce them.' Mill, after some hesitation, goes back substantially to McCulloch's definition.

Modern writers have gradually recognized a necessary ambiguity or series of ambiguities in the term wealth. (a) It may be expressed either as an inventory or as a valuation—the distinction made in the definitions above given. (b) It may be either public or private (see NATIONAL WEALTH). In the former case it consists of things, in the latter case of titles. (c) It may be understood, or not understood, as including personal qualities. (d) It may be measured as a flow (income) or as a fund (CAPITAL, q. v.). If we measure it as capital, it consists only of material things; if we measure it as income, it should include services also. (A.T.H.)

Weariness: see FATIGUE.

Weber, Ernst Heinrich. (1795–1878.) Born at Wittenberg, Germany; educated at Leipzig in medicine; professor of comparative anatomy at Leipzig, 1818; of physiology, 1840. In addition to his contributions to anatomy and physiology, he had an important influence in the founding of the science of experimental or physiological psychology. See WEBER'S LAW, and SENSORY CIRCLES.

Weber, Joseph. (1753–1831.) Born at Rain in Bavaria. After holding various offices in the Roman Catholic Church, he became professor of philosophy and physics at Dillingen in 1790. After the victory of the Jesuit party, he was professor of physics, 1816–21. He died as vicar-general at Augsburg.

Weber's Law: Ger. *Weber'sches Gesetz*; Fr. *loi de Weber*; Ital. *legge di Weber*. A generalization made by Weber to the effect that the least added difference of stimulus that can be noticed is a constant proportional part of the original stimulus.

Thus, if one pound when lifted can just be discriminated from one pound and one ounce, ten pounds cannot be discriminated from ten pounds and one ounce, but the

difference needs to be ten ounces. The law is thought by Fechner, Wundt, and others to hold approximately for stimuli, except those very small or very large. In a general way, the least noticeable difference is for simultaneous lights $\frac{1}{100}$, for successive lights $\frac{1}{10}$, for sounds $\frac{1}{4}$, for pressures $\frac{1}{10}$, for lifted weights $\frac{1}{20}$, and for length of lines $\frac{1}{100}$. Cf. FECHNER'S LAW, and PSYCHOLOGICAL METHODS.

Literature: that of experimental PSYCHOLOGY (q. v.); see also BIBLIOG. G, 1, d, and the Psychol. Index, 1 ff. in loc. (J.M.C.C.)

Weight Sensation [ME. *weght, wight*, from AS. *gewiht*]: Ger. *Empfindung der Schwere*; Fr. *sensation de poids*; Ital. *sensazione di peso* (or *barica*). Sensation from the active supporting or lifting of weights.

This usage is recommended. The sensation is probably a compound of TENDON SENSATION (q. v.), MUSCLE SENSATION (q. v.), and PRESSURE SENSATION (q. v.).

Literature: BASTIAN, *Brain as Organ of Mind*, 695; JAMES, *Princ. of Psychol.* ii. 189 ff., 486 ff.; MÜLLER and SCHUMANN, *Pflüger's Arch.*, xlv. 37 ff.; FULLERTON and CATTELL, *Perception of Small Differences* (1892); SANFORD, *Course in Exper. Psychol.*, expts. 33, 34, with bibliog.; see HAPTICS. (J.M.B.)

Weismannism: Ger. *Weismannismus*; Fr. *Weismannisme*; Ital. *Weismannismo*. The distinctive biological theories of August Weismann.

The following biological conceptions are generally associated with Weismann's name: (1) That there is continuity of the germ-plasm in a series of organic generations. (2) That modifications of organs and tissues acquired in the course of individual life are not inherited. (3) That the germ-plasm contains the 'determinants,' or structural germs, from which all the organs and tissues are developed, being appropriately distributed in the course of cell multiplication. (4) That natural selection is the all-sufficient cause of organic diversity. This list could easily be increased by introducing reference to Weismann's views as to PANMIXIA, GERMINAL SELECTION, &c. (see those terms).

The diagram given herewith illustrates Weismann's views.

Literature: A. WEISMANN, *Essays*, i, ii; *The Germ-Plasm*; Romanes Lecture, 'On the Effect of External Influences on Development'; and 'Germinal Selection.' Consult recent expository works on organic EVOLUTION (q.v.). Criticisms of Weismannism are ROMANES, *Weismannism*; O. HERTWIG, *Zeitsch. und Streitfragen d. Biol.*; COPE, *Primary Factors of Organic Evolution.* (C.L.L.M.)

Weiss, Christian. (1774-1853.) Born near Leipzig and educated in that city. After 1791 he studied there philology, philosophy, natural science, and theology. Doctor of philosophy in 1795, he became Privatdocent in 1796; assistant professor in philosophy, 1801; director of the Lyceum at Fulda in 1805; and councillor to the government and schools at Merseburg in 1816. He died at Merseburg.

Well-being and Welfare: Ger. *Wohlsein*, *Wohlfahrt*; Fr. *bien-être*; Ital. *prosperità*, *benessere*. The attainment of that which constitutes the HIGHEST GOOD (q.v.) in this or that situation.

This leaves the question of the highest good open to determination; it also leaves open the question as to its absolute or relative determination in this or that situation. (J.M.B.)

Aristotle holds that well-being (*εὐδαιμονία*) is, by universal acknowledgment, the good. It is in their interpretation of well-being that men differ, some holding that it is pleasure, others that it is wealth, honour, &c. Aristotle's own view is that it is activity of the soul in accordance with its own proper virtue or excellence, i.e. rationality. The object of politics, according to Aristotle, is well-being (*εὖ ζῆν*), as distinguished from mere life (*ζῆν*) (see *Politics*, Bk. III. chap. ix). J. S. Mill distinguishes similarly between the interests of being or security and those of well-being; it is with the former that justice is concerned, hence its paramount importance (Mill, *Utilitarianism*, chap. v). The evolutionary school have made welfare a central conception of their ethics. Darwin makes the general welfare the ultimate ethical conception (see *Descent of Man*, chap. iv). Spencer interprets welfare as pleasant or happy life (see *Princ. of Eth.*, Pt. I. chap. iii). Contemporary German moralists also give prominence to the idea of welfare; for example, Paulsen: 'The term welfare (*Wohlfahrt*) may also be employed to designate this goal [the perfect life], which would suggest the subjective element involved in it, or the fact that such a life yields satisfaction (*Wohl-*

gefühl)' (*Syst. of Eth.*, Eng. trans., *Introd.*, § 3). 'The word welfare, finally, seems suited to designate the highest good in its twofold aspect: it shows, first, that the highest good is an objective content of life, consisting in the perfect exercise of all human psychical powers; then it also suggests that such a life is accompanied with pleasure, and hence that pleasure is not excluded from the perfect life, but included in it' (*ibid.*, Bk. II. chap. i. § 1). (J.S.)

Werewolf [AS. *wer*, man, + *wulf*, wolf]: Ger. *Werwolf*; Fr. *loup-garou*; Ital. *lupomannaro*. A conception belonging to the superstition that human beings can be turned into wolves, while retaining human intelligence.

Lycanthropy was the term applied to this in ancient times, and became equivalent to the transformation of human into animal forms. The werewolf superstition has assumed various forms in different times and countries. It was believed in as an animal that appeared in various shapes (sometimes invisible), prowled about, and devoured children. The term was also applied to a morbid assumption or simulation of animal habits and instincts, and in this sense was a form of insanity with a tendency to become epidemic. (J.S.)

Westminster Confession: Ger. *Westminster'sches Glaubensbekenntniss*; Fr. *Confession de Westminster*; Ital. *Confessione di Westminster*. The doctrinal system formulated and adopted by the Westminster Assembly of Divines (1644-7) and embodying the form of Calvinistic theology which constitutes the distinctive creed of Presbyterianism.

The Westminster Confession is the last of the great Calvinistic creeds. It embodies all the distinctive features of Calvinism in a statement notable alike for its clear and comprehensive conceptions, its accurate definitions, and the fitting language in which it is expressed. Its principal feature is the supreme emphasis it places on God's sovereignty and man's absolute dependence on divine grace for salvation, as the groundwork of all the other features of the system. The Confession still preserves substantially the form given to it by its authors.

Literature: P. SCHAFF, *Creeds of Christendom* (4th ed., 1884); A. HODGE, *Commentary on the Westminster Confession* (1869); JOHN MCPHERSON, *The Westminster Confession* (1881); B. B. WARFIELD, *Presb. and Reformed Rev.*, April, 1901. (A.T.O.)

Whewell, William. (1794-1866.) Studied, graduated, and became a fellow at Trinity College, Cambridge; took orders in the Church of England; professor of mineralogy at Trinity, 1828-32, of moral theology or casuistry, 1838-55; master of Trinity College after 1841; Vice-Chancellor of Cambridge University after 1855.

Whole (and Parts) [AS. *hal*, healthy; Gr. *ὅλος*, entire]: Ger. *das Ganze*; Fr. *le tout*; Ital. *il tutto*. The old definition is: 'Totum est quod constat plurium rerum unione.' Psychologically, whatever is treated as a single object though capable of treatment as two or more objects (parts of the whole): by 'treated' meaning 'thought of,' 'attended to,' or otherwise 'acted upon.' (C.S.P.—J.M.B., G.F.S.)

We may say that a whole is an *ens rationis* whose being consists in the copulate being of certain other things, either not *entia rationis* or not so much so as the whole; so that a whole is analogous to a *collection*, which is, in fact, a special kind of whole. There can be no doubt that the word whole always brings before the mind the image of a collection, and that we interpret the word whole by analogy with collection. The idea of a collection is itself, however, by no means an easy one to analyse. It is an *ens rationis*, abstraction, or fictitious subject (but the adjective must be understood in a broad sense, to be considered below), which is individual, and by means of which we are enabled to transform universal propositions into singular propositions. Thus, the proposition 'all men are mortal,' with a new subject and new predicate, appears as 'The collection of men is a collection of mortals'; just as, for other purposes, and by means of other abstractions, we transform the same proposition into 'The character of mortality is possessed by every man'; and the members of the collection are regarded as less fictitious than the collection. It very often happens that an object given in direct perception as an individual is, on closer scrutiny, seen to be identifiable with a collection of parts. But it does not seem to be strictly accurate to say that the larger object of perception is identical with that abstraction, the collection of the smaller objects. It is rather something perceived which agrees in its relations with the abstraction so well that, for convenience, it is regarded as the same thing. No doubt the parts of a perceived object are virtually objects of consciousness in the first precept; but it is useless to try to extend logical relations to the sort of

thought which antecedes the completion of the percept. By the time we conceive an object as a collection, we conceive that the first reality belongs to the members of the collection and that the collection itself is a mere intellectual aspect, or way of regarding these members, justified, in ordinary cases, by certain facts. We may, therefore, define a collection as a fictitious (thought) individual, whose being consists in the being of certain less fictitious individuals.

Many adjectives are used to distinguish different kinds of wholes. Certain of the phrases may be defined.

Actual whole: any whole which cannot exist without the existence of its parts. Usually identified with the *Constitute whole*. Monboddo's definition (*Ancient Met.*, i. 479) is not quite accurate.

Collective whole, or *aggregate whole*: defined by Chauvin as 'that which has material parts separate and accidentally thrown together into one, as an army,' &c. But the example shows that organization does not disqualify a whole from being called *collective*, although the term *totum per aggregationem* will no longer be applied to it, in that case. In so far as a whole is collective, any other relation between its parts is put out of view.

Composite whole: a term of Burgersdicius, who (*Inst. Met.*, I. xxii. § 7) defines it as 'quod ex duabus partibus constat quarum una est in potentia ad alterum et altera vice versa actus est alterius.' It includes the whole by information and the whole by inference.

Comprehensive whole: a whole of logical comprehension.

Constituent whole: a whole which is essential to its parts. See UNIVERSAL.

Constitute whole: a whole whose parts are essential to it. See *Actual whole* (above).

Continuous whole: a continuum regarded as a whole. In order to define it, it would first be necessary to define CONTINUITY (q. v.). Now we have, perhaps, not yet succeeded in analysing the conception of continuity; for what the mathematicians call by that name, such as the relations of all real quantities capable of being designated to an indefinite degree of approximation by means of a whole number and a decimal, does not answer the requisites of the problem.

Copulative whole: a whole consisting of a sign which is essentially applicable to whatever certain signs, called its parts, are all applicable, but is essentially inapplicable to

anything to which any one of these signs is inapplicable.

Definite whole: a whole constituted by genus and difference.

Definitive whole: see *Definite whole* (above).

Discrete whole: the same as a *Collective whole* (above).

Disjunctive whole: a whole consisting of a sign which is essentially applicable to whatever any one of certain signs, called its parts, is applicable, but is essentially inapplicable to anything to which none of these parts is applicable.

Dissimilar whole: same as *Heterogeneous whole* (below).

Essential whole: great confusion exists in the use of this very common expression. Aquinas (*Summa Theol.*, Pt. I. lxxvi. 8) uses it in a broad sense which would make it about equivalent to Burgersdicius' composite whole, or perhaps broader. On the other hand, it is sometimes restricted to the whole *per informationem*, and this is perhaps the best settled use. But others make it include the physical and the metaphysical whole as its two species.

Extensive whole: a whole of logical extension, usually called a subjective or logical whole.

Formal whole: a comprehensive whole, especially of essential comprehension. See *Actual whole* (above).

Heterogeneous whole: a term of Aquinas; a whole whose parts are dissimilar from the whole.

Homogeneous whole: a term of Aquinas; a whole whose parts are similar to the whole, as the parts of a whole of water are.

Integral whole (a term in common use since Abélard's time): Blundevile (1599) says, 'Whole integral is that which consisteth of integral parts, which though they cleave together, yet they are distinct and severall in number, as man's body, consisting of head, brest, belly, legs, &c.' The usual definition is 'quod habet partem extra partem,' which restricts it to space. Burgersdicius, however, says that parts which differ in their ordinal places are *partes extra partes*.

Integrate whole: a pedantic variant of *Integral whole* (above).

Logical whole: same as *Universal whole* (below).

Mathematical whole: same as *Integral whole* (above).

Metaphysical whole: a whole in that respect in which a species is the whole of its genus and difference. See *Formal whole* (above).

Natural whole: a term proposed by Hamilton to replace Comprehensive or Metaphysical whole; as if that were not sufficiently provided with aliases under which to hide itself.

Negative whole: a unit regarded as a whole, as in the phrases 'deus totus est ubique,' and 'anima est tota in toto corpore.'

[*Objective whole*: a mental object apprehended as a single real thing.—J.M.B.]

Physical whole: a whole compounded of substance and accident; but some say of matter and form; and some that both come to the same thing. In the peripatetic view, however, substance is form, not matter.

Positive whole: a whole consisting of parts. See *Negative whole* (above).

Potential whole: same as *Universal whole* (below); so called because the genus does not actually, but only potentially, contain the species, &c.

Potestative whole: a term of Aquinas; equivalent to *Potential whole* (above).

Predicative whole: a whole of logical depth.

Quantitative whole: same as *Integral whole* (above).

Similar whole: see *Homogeneous whole* (above).

Subjective whole: same as *Subjective whole* (below).

Subjective whole: a very venerable name for *Universal whole* (below).

Substantial whole: a whole of logical breadth.

Universal whole: see UNIVERSAL.

Whole by accident: such a whole as neither essentially belongs to the parts nor the parts to it.

Whole by aggregation or aggregative whole: same as *Collective whole* (above) in an exclusive sense.

Whole by information: a compound of act and power in the same kind, such as man, according to the Aristotelian theory of the soul.

Whole by inherence: same as *Physical whole* (above).

Whole by itself or per se: a whole which essentially belongs to its parts or its parts to it. (C.S.P.)

Wild (in biology) [AS. *wild*, wilful]; Ger. *wild*; Fr. *sauvage*; Ital. *selvatico*. Untamed; used of animals living in their native habitat, as opposed to DOMESTICATED ANIMALS (q. v.). (J.M.B.)

Will [AS. *wille*]; Ger. *Wille*; Fr. *volonté*; Ital. *volontà* (see also TERMINOLOGY, English, 'Will'). (1) CONATION (q. v.).

(2) That conative organization of which VOLITION (q. v.) is the terminus or end-state.

(3) VOLITION (q. v.).

The use of the term 'will' is so varied that it is impossible to get from the history any exclusive meaning. Three usages hold their own for the reason that they are associated with the different points of view from which the subject is approached. If we take a philosophy which approaches the type called VOLUNTARISM (q. v.), we have definition (1); and so broad may its view of conation become that its essential meaning as a mental function seems largely to disappear; this is illustrated in Schopenhauer's usage as reflected in the title of his work *The World as Will and Idea*. If we come to will from the other extreme—that of the determination of a conation, in its distinctness from other mental determinations, in a state of consciousness in which this element is dominant—we have definition (3), for which volition only is will—i.e. the case in which mental organization takes on for the first time the character and complexity to which a new name can be given.

Between these two views lies another, that given under (2) above. This commends itself not only because it is a *via media*, but also for intrinsic reasons. The term conation is justified mainly because it can be used for the active tendency in the abstract, apart from any concrete determination. It is thus an element in the structure of mind, and it is also that which the concrete active processes have in common. It is what the Germans call the *Inbegriff* of the various phenomena of action. The word conation, therefore, fills the requirement of the philosophical definition given under (1). On the other hand, volition is the term for the concrete determination of conation at the level in which the highly conscious form of organization called deliberation and choice issues in its terminus. This suffices for (3). But the stretch of the mental life, with all its forms of active determination, impulse, tendency, disposition, non-volitional-yet-voluntary action, all this remains. These are conation in the concrete, but they may not be conation determined in an actual terminus by volition. Volition considered as the limiting case of determination is included, since it is, like the earlier determinations, also one of conation.

These reasons lead us to recommend the second definition of will. It is the general notion of which all concrete conative determinations are concrete instances. It includes the

entire active life, and allows a genetic theory of will from its earliest stages. It refuses, however, to call by this name the elementary and hypothetical abstraction called conation, and hypostatized in various ways as 'conatus,' 'will to live,' 'unconscious will,' &c. Such an extension is a direct subversion of the distinction between the PSYCHIC AND THE PSYCHOLOGICAL (see that topic); only the concrete forms of action are psychic and immediate to the mental subject; and the going over to the objective or psychological point of view is such a transition in meaning that no single term can be used in both the senses.

It is believed that this recommendation is in accord with the views of the greater number of competent modern psychologists. Cf. also ACTION.

Literature: for historical citations in great number see EISLER, Wörterb. d. philos. Begriffe, 'Wille.' See also the systematic psychologies, BIBLIOG. G, 2, w, and the topics cited. (J.M.B., G.F.S.)

Will (disorders of): Ger. *Willensstörungen*, *Willensdefekte*; Fr. *troubles de la volonté*, *aboulie*; Ital. *disturbi della volontà*, *disboulie* (E.M.). Impairment of normal volition.

Disorders of the will, like those of other functions, seem divisible into those of excess and defect; but the former term requires a special interpretation. An excessively vigorous will is not a disorder; but the term *hyperboulia*, which is literally equivalent to this, indicates an abnormal tendency to action. The tendency of an impulse, under the suggestion of a thought or motive, to engender execution, is excessive or abnormal. But this in turn may properly be regarded as a deficiency in inhibition, i.e. of the restraining power of a higher over a lower will-mechanism. The term *dysboulia*, which naturally indicates a difficulty in the exercise of the will, may also be considered as a form of *aboulia*, which indeed has come to be regarded as a general term embracing all the typical forms of morbid disorders of the will, but referring more specifically to its deficiency or extinction.

Aboulia may be defined as loss, lack, or impairment of the power to will or to execute what is in mind. In this condition there is no paralysis or disorder of the muscular system, and frequently there is no lack of desire or of realization of the end sought; but the transition from motive and desire to execution becomes abnormally difficult or impossible. The patient, as a rule, realizes his own condition, may believe that his will

power has been usurped by another person or agency, exerts himself violently to perform some simple act, and frequently succeeds in overcoming the barrier that stands between thought and action. The cases cited by Ribot of an aboulie patient keeping a servant standing half an hour before he succeeded in taking from the servant's tray a glass of water, or of another writing a legal document, but struggling a hundred times to put the flourish to his signature, are salient instances of this condition. In less extreme cases the aboulia appears as a form of persistent irresolution, of which De Quincey's *Confessions*—in his case the condition was due to and aggravated by opium-poisoning—furnish a suggestive instance. In the most extreme cases (in certain forms of melancholia) there is practically a total extinction of the will, the patient, if left to himself, sitting listless, impotent, and passive. Somewhat different, yet allied, is the extinction of the will found in extreme cases of psychic concentration, as in religious ecstasy and hypnotic trance. See TRANCE, and HYPNOTISM.

The more precise analysis of this aboulie state is difficult. Ribot distinguishes between aboulia from lack of impulse and from excess of impulse; the cases above cited belong to the former group, while those in which excessive and irrational fear or argumentation paralyzes the springs of action evidence the latter. Such fears as that of open places (AGORAPHOBIA, q. v.), or excessive balancing of motives and quibbling with pros and cons, interfere with execution quite as much as weakness of will without fear or indecision. Ribot further holds that both forms involve an impairment of emotional sensibility, an absence or bluntness of the emotions which normally incite to action. To this it may be objected that frequently there is no apathy, but an intense sensitiveness regarding the inability to carry out what is desired. Some authors distinguish three causes of aboulia—weakness of motives, doubt or fear as to the nature or outcome of the action proposed, and an embarrassment or excessive number of ideas which offset one another and prevent definite action. If we regard a normal action of the will as involving a motive sufficient and perceived, and an uninterrupted passage-way towards a definite action, the three forms of interference with the normal sequence of this process would be (1) an insensibility to the motives—lack of action by reason of lack of effective impulse; (2) a damming of the

stream of action by reason of irresolution; (3) excessive hesitation as to the direction which the action is to take. It is further to be noted that the automatic and habitual functions may be readily performed while those involving consciousness are interfered with. Aboulia may also appear as a failure to inhibit or check semi-automatic actions, and then becomes allied to excess of impulse (hyperboulia) and general weakness of will, or difficulty in its exercise (dysboulia). Closely allied to and forming a part of the symptoms of aboulia in many cases is a difficulty in maintaining voluntary attention. Cf. ATTENTION (defects of); Hugonin, *Troubles de la Volonté* (1892); Richet's *Dict. de Physiol.*, sub verbo; Janet, as cited below. Impairment of will in various forms is especially prominent in NEURASTHENIA (q. v.), and forms a most characteristic symptom of it. Aboulia (or dysboulia) is also a frequent symptom in many forms of nervous weakness which involve no impairment of the intelligence. In cases of insanity it 'is most commonly found in simple melancholia or in the early stages of mania or of general paralysis' (Hyslop). (J.J.)

Literature: RIBOT, *Diseases of the Will* (Eng. trans.); HYSLOP, *Ment. Physiol.* (1895), 448 ff.; JANET, *Automatisme psychol.*, and *Névroses et des Idées fixes*; BALDWIN, *Ment. Devel. in the Child and the Race*, chap. xiii. § 4; the textbooks of mental diseases. See also MOVEMENT (control of). (J.J.—L.M.)

Will (free): see FREE AND FREEDOM, DETERMINISM, INDETERMINISM; and cf. MIND AND BODY, PARALLELISM (psychophysical), and UNIFORMITY (4), (d, e).

Will (in law): Ger. *Testament, letzter Wille*; Fr. *testament*; Ital. *testamento, ultima volontà*. A voluntary disposition of all or part of a man's property or rights to take effect only upon his death.

Nuncupative will: an unwritten will. **Olographic** (or **holographic**) **will:** one wholly in the handwriting of the testator. **Undutiful will:** one disinheriting, in whole or part, kindred in the natural line of succession, contrary to the rules of law (*Inst. of Just.*, ii. 18, *de inofficioso testamento*).

A man has no natural right to dispose of his property after his own death by an act which is to take effect only after that event (*United States v. Perkins*, 163 U. S. Law Reports, 625, 627).

If his will survives him, it must be by force of some positive law (Heineccius, *Elementa Iuris Naturae et Gentium*, Lib. i. 287). Grotius

regards this law as simply clothing a natural right in solemn form (*De Iure Belli et Pacis*, Lib. II. chap. vi. 14); so Puffendorf (*De Officio Hominis et Civis*, Johnson's ed., Lib. I. 12, note).

Laws taxing testamentary successions rest upon this ground, that the capacity of taking under a will is a privilege granted by the state (as is also that of succession by inheritance, in case of intestacy).

Primarily, the design of a will is to dispose of property, but it may be confined to disposing of rights not in the nature of property, e.g. by its doing no more than to exercise the right of naming an executor, or a guardian for an infant child. (S.E.B.)

Will-Philosophy: see VOLUNTARISM.

Will to Believe: Ger. *Wille zum Glauben*; Fr. *volonté de croire*; Ital. *volontà di credere*. The exercise of will in matters of belief; involving a normal conative factor over and above the intellectual processes involved in the determination of the belief.

Given currency by James in the title essay of his volume *The Will to Believe*. What James means is 'the state of mind of a man who finds an impulse in him towards a believing attitude, and who resolves not to quench it simply because doubts of its truth are possible. Its opposite would be the maxim: Believe in nothing which you can possibly doubt.' (J.M.B.)

Its negative would be: Regulate your degree of belief in exact accordance with the degree of evidence that is accessible to you. (C.L.F.)

Literature: JAMES, as cited; MILLER, Int. J. of Ethics, ix. (1898) 169; discussion in Psychol. Rev., iv. (1899) 150. (J.M.B.)

William of Champeaux: see CHAMPEAUX, and REALISM (1).

Wisdom [AS. *wis*, wise]: Ger. *Weisheit*; Fr. *sagesse*; Ital. *sapienza*. The more direct and intuitive forms of apprehension or insight as contrasted with the more reasoned or discursive. (J.M.B.)

Wisdom (*σοφία*) to Plato is one of the cardinal virtues, both of the state and of the individual. It is the attribute of the highest part in either case; of the legislators in the state, of the rational faculty in the individual. Through the wisdom of this, its highest part, the whole is, in either case, wise. Aristotle distinguishes two kinds of wisdom—the speculative (*σοφία*) and the practical (*φρόνησις*). The former has to do with the unalterable and the superhuman, with the absolute nature of things; it is

synonymous with science, in the largest sense of the term, intuitive and demonstrative. The latter has to do with the contingent and particular relations of human experience, with the details of life and conduct; itself an intellectual virtue, it is the presupposition of all moral virtue, whether in the individual or in the state. (J.S.)

Wisdom (divine). The wisdom of God embraces both rational and volitional elements, and is that union of knowledge and goodness to which the creation of the world is ascribed.

In Greek thought the term *νοῦς* stood for abstract intelligence or reason, while Logos represented reason manifesting itself. Christian thought further emphasizes the practical side of the Logos, which becomes in Christ the divine thought or reason energizing as the Creator and Redeemer of the world. Christ is sometimes called the divine wisdom. If wisdom be distinguished from realizing energy, it embodies itself in the ideal, planned or purposed, world which is presupposed in the actual. Cf. ATTRIBUTES (of God), and LOGOS. (A.T.O.)

Wise Men (the seven): Ger. *die Sieben Weisen, die Gnomiker*; Fr. *les Sept Sages (de la Grèce)*; Ital. *i sette Savii*. Thales, Solon, Chilon, Pittacus, Bias, Cleobulus, Periander, Anacharsis (eight for seven).

For the sententious sayings for which they are respectively famous see Eisler, *Wörterb. d. philos. Begriffe*, 'Gnomiker.' (J.M.B.)

Wish. Used for DESIRE (q. v.). (J.M.B.)

Wit [AS. *witt*, knowledge]: Ger. *Witz*; Fr. *esprit*; Ital. *spirito*. The COMIC (q. v.) so far as it turns upon more formal or intellectual relationships and does not excite real interests and emotions.

The wit quality, like that of beauty, includes disinterestedness. Wit, therefore, is more purely AESTHETIC (q. v.), humour less. The intellectual quality is seen in the use of the term for intelligence and mental alertness. (J.M.B.)

Witchcraft [AS. *wicce*, witch, + *craft*, strength]: Ger. *Zauberei*; Fr. *sorcellerie*; Ital. *stregoneria*. Magical effects of various kinds due to possession, the person possessed being known as a witch. See MAGIC. (J.M.B.)

Of the many aspects of witchcraft—historical, legal, religious, anthropological, psychological, and pathological—only those will be here considered that contribute to an appreciation of its psychological status. In this aspect it presents a widespread belief with many anthropological varieties; it illustrates the

growth of mental epidemics; it illuminates significant stages in the history of culture; and it offers for examination groups of abnormal mental phenomena in which science traces analogies and relations to recognized forms of nervous and mental diseases.

As a practice witchcraft falls under the general head of MAGIC (q.v.), the unusual effects being referred to the actions of charms and potent drugs, of mystical formulae and occult incantations; to strange influences, such as the possession of the evil eye, or to connivance with the supernatural; and in later superstitions to the power gained by compact with the devil and the attendance of imps and familiar spirits. Anthropologically, it finds a widespread representation among primitive peoples in their interpretations of the origin of disease, of the failure of crops, and of every sort of ill fortune that may befall themselves and their belongings. Disease is quite generally regarded as due to the secret machinations of an enemy or to the possession by a spirit, who must be appeased or exorcized. If the crops fail, if the cattle die, if the children fall sick, some one is inflicting these calamities by secret charms or witchcraft. The native Australians do not recognize a natural death, such a calamity being explicable only by bewitchment. Travellers in the Pacific Islands describe a special set of professional disease-makers, who introduce the disease by incantations and spells exercised upon a lock of the desired victim's hair, or a bit of his clothing, or his effigy, or some object which represents him, or even his name. The tortures and maledictions visited upon these are then transferred by a sympathetic magic to the real victim. Hence the dread prevalent among these people of allowing bits of hair, or clothing, or nail-parings to pass into the possession of others. Amongst historical people, from Chaldeans to Anglo-Saxons, beliefs and practices of witchcraft are readily traced in various forms, particularly as influenced by theological conceptions; and these beliefs survive in more or less transparent disguises in current and declining superstitions.

The most important epidemic of witchcraft was that which spread irregularly over Europe mainly in the 16th century. First in Italy and France, then in Germany and England, thousands upon thousands of persons were accused of witchcraft, were tried by bigoted tribunals, were tortured to elicit confessions, and met a horrible death at the stake. The

later outbreak of the mania in New England towards the close of the 17th century, though far less extensive, is equally significant. Such suspects were accused of causing sickness and death, and of producing all manner of evils. 'Your grace's subjects pine away even into death; their colour fadeth, their flesh rotteth, their speech is benumbed, their senses are bereft,' says a preacher to Queen Elizabeth. These things were assumed to be possible only by the doings of witches, whom it was a duty to find and destroy. Under this dominant predisposition to see in all things evidences of witchcraft, an elaborate system of beliefs regarding witches grew up; many of the wisest in their lands ignored justice as well as judgment, regarded nothing as too improbable to be admitted as evidence of compact with the evil one, and gave themselves up to a passion for witch-finding, hardly less fervid in its intensity nor less awful in its methods and results than the most bitter religious persecutions. Indeed, both were similarly motivated, and are recorded in equally dismal pages of human history. The witches were supposed to have sold their souls to the devil, receiving in return the power to work spells and create diseases; they could change themselves or others into animal forms, and gathered rare herbs and uncouth trifles to prepare magic potions; they were supposed to assemble at night on the witches' sabbath, and then in a mock religious ceremony receive instructions from Satan himself; they were believed to suck the blood of innocent babes, and to indulge in unspeakable forms of sacrilegious and obscene orgies; they could make use of their diabolic powers by flying to these meetings mounted on brooms; their behests were carried out by imps and familiars. So, too, in the tests for witchcraft, the marks of the devil were sought for: the floating test was the most usual. If the witch could float, it was evidence of her witchcraft; if she sank, she died innocent. Pin-pricks located the spots on the body which were insensible to pain, and showed where the touch of the devil had been given. Other more human beliefs utilized as tests consisted in observing whether the witch could repeat the Lord's Prayer, whether it was true that she could weep only three tears, or out of the left eye only, or whether she could prove herself heavier than the Bible. In certain cases, when the hunting of witches was in its decline, the satisfaction of these tests made possible a vindication of the charge. But an equally important, if

not more important, factor in the charges which brought victims to the stake and the scaffold was the imagination and far-fetched accusations of terror-stricken and irresponsible witnesses. Again and again children gave testimony against uncanny old women and were thrown into convulsions in their presence; the most trivial as well as the most outrageous charges were sufficient for condemnation. In German villages one and another testified to having seen the accused in curious garb dance on the green with imps or with the devil transformed in some human guise. The accused was put under torture, and to escape further agony, and half-crazed with fear and pain, confessed to the deeds imputed to her, and often implicated others; and so the flames were kept burning. A list of those beheaded and then burnt, or burnt alive, as witches in the town of Würzburg from 1627-9 records twenty-nine such occasions, and contains the names of one hundred and fifty-one persons. Of these as many were men as women, and thirty were children; all stations of life were represented, though the victims were mostly of the lower classes. The decline of the mania, the gradual assertion of the saner minds in the community, the enlistment of those in high places to suppress the persecutions, the vigorous attacks, usually based on theological argument, upon witch-hunting, the havoc caused by the insecurity of life amongst high and low—these and many other factors contributed to the establishment of more human and enlightened views. Witchcraft declined because of the gradual development of a mode of thought in which the belief found a slighter foothold.

Modern science recognizes in the phenomena of witchcraft many illustrations of nervous and mental symptoms. Quite a large number of the witches accused themselves of imaginary crimes, a common symptom of a type of melancholia, and often connected with religious absorption and a morbid conscientiousness. The readiness with which suggestion acts upon young minds, and induces them to accept as real ideas and actions which they experience only in imagination, is a common principle of modern psychiatry. The contagion of such hallucinatory beliefs is abundantly illustrated in other fields than witchcraft. That many so-called witches gave evidence of 'possession,' and presented the uncontrollable actions and utterings characteristic of hysteria, cannot be doubted. The anaesthetic spots are a frequent hysterical symptom, as is also

the extreme suggestibility of the patient. That fear and torture often brought on conditions of irresponsibility and insanity, in which the wildest charges were acknowledged, is also evident. Add to this the ordinary motives of hate and spite and envy and unpopularity, the benighted condition of the masses of the people, the misguided religious fervour, and a considerable portion of the data necessary to a psychological interpretation of the phenomena is at hand.

Literature, general and historical: LECKY, *Hist. of Rationalism in Europe*, i. chap. i; and art. *Witchcraft*, in *Encyc. Brit.* (9th ed.); WHITE, *Hist. of Warfare of Sci. with Theol.*, chaps. xii, xv, xvi; SOLDAN, *Gesch. d. Hexenprocesse* (1843; revised by Heppe, 1880); MAURY, *Hist. de la Magie* (1860); BALDI, *Hexenprocesse in Deutschland* (1874); JANSSEN, *Hexenwesen und Hexenverfolgung*, in *Gesch. des deutschen Volkes*, viii (1892); HAAS, *Die Hexenprocesse* (1865). Anthropological: TYLOR, *Early Hist. of Mankind*. Specially psychological: SNELL, *Hexenprocesse und Geistesstörung* (1891); BEARD, *Psychol. of Salem Witchcraft* (1882). (J.J.)

Wolf (or Wolff), Christian. (1679-1754.) Attended school at his birthplace, Breslau, Germany, and the universities at Jena and Leipzig. Studied theology, mathematics, and philosophy. Lectured at Leipzig on mathematics and philosophy; professor of mathematics at Halle, 1707; he later lectured in physics and philosophy. He was very successful, but was accused of heresy and ordered by a cabinet to leave Prussia. Lectured for several years at Marburg in Hesse-Cassel; recalled to Halle, 1740; made chancellor of the university, 1743. Died at Halle. See DOGMATISM.

Wonder [AS. *wundor*, surprise]: Ger. *Verwunderung*, *Staunen*; Fr. *étonnement*; Ital. *meraviglia*. That mingled feeling of surprise and awe which arises in view of phenomena that surpass our power and knowledge and which we ascribe to a supernatural or superhuman origin.

Wonder as a religious emotion is largely subjective and passive. It is called forth by the great and mysterious. Greatness alone without mystery would not call it forth. On the other hand, the mysterious alone excites curiosity, but not wonder. Nor would the absolutely mysterious call it forth. It would be simply a bluff to our intelligence. Wonder is the feeling which arises in view of something great about which we have

some knowledge, but whose inner nature we cannot penetrate. Cf. RELIGION (psychology of, also for literature). (A.T.O.)

Woolston, Thomas. (1669–1733.) English divine, born at Northampton; educated at Sidney Sussex College, Cambridge; later a fellow there. Died in prison, into which he was thrown on account of his book on *The Miracles of our Saviour*.

Word [Goth. *ward*; Teuton. *word*; Lat. *verbum*, word or name]: Ger. *Wort*; Fr. *parole*; Ital. *parola*. In Christian theology: used (1) as an equivalent of the Greek term LOGOS (q. v.); and (2) as a designation of the Old and New Testament Scriptures as the revealed wisdom of God. See also SCRIPTURES, and BIBLE. (A.T.O.)

Word-blindness: see ALEXIA, and BLINDNESS (mental), and cf. SPEECH AND ITS DEFECTS, *passim*.

Word-deafness: see APHASIA (sensory), and DEAFNESS (mental).

Word Method: Ger. *Wort-Methode*; Fr. (not in use); Ital. *metodo di parola*. An analytic method of learning to read, wherein the word is first taught as a whole, being afterwards analysed into its component letters. Cf. ALPHABET METHOD. (C. De G.)

Work [AS. *worc*, *werc*]: Ger. *Arbeit*; Fr. *travail*; Ital. *lavoro*. The measure of the energy expended in moving a body or system against the action of a force tending to retard or impede the motion.

If a particle be made to move through a distance p in the direction opposed to a force of intensity f , the work done on the particle is the product pf . In the case of a system, the total work done is the sum of these products formed for each individual particle. The force f may be that of friction, generated when machinery turns, or when a load is dragged over a level floor. In this case the energy expended in doing the work is transformed into the heat produced by the friction. The force may also be that of attraction, as when water is pumped to a higher level. To pump a weight W of water to a height h requires the work Wh . The energy expended in doing the work is then transformed into energy of position, one form of potential energy. If the force f does not act in the direction of the motion, its component in that direction must be used for f . The work is then $pf \cos a$, a being the angle which the direction of the force makes with that of the motion.

It will be seen that work is not a special

form of energy, but only an expression for a quantity of energy transformed.

Internal work is the measure, in terms of energy, of a change in the molecular constitution of a body, produced by the expenditure of energy, generally in the form of heat. (S.N.)

Work (in economics): see LABOUR.

Work (mental). (1) The performance of mental functions for the sake of the results attained, as contrasted with PLAY (q. v.).

(2) The effects of mental functions as measured in relative FATIGUE (q. v., also for literature). (J.M.B.)

Works (good, &c., in theology): Ger. *Werke*; Fr. *œuvres*; Ital. *opere*. The actions performed after conversion in obedience to the law or will of God, and either giving the doer merit before God or constituting evidence that he is in a state of grace.

The great opposing tendencies in the sphere of doctrine are embodied in Augustinianism and Pelagianism and their various modifications; the former denying all merit to works except as evidences of grace, the other ascribing merit to works in the procurement of salvation. This latter view rests at the basis of the Roman Catholic doctrines of penance and supererogation. The Augustinian view has dominated Protestant Christianity.

Literature: see PENANCE, PELAGIANISM, AUGUSTINIANISM, and JUSTIFICATION. (A.T.O.)

World [AS. *wer*, man, + *eald*, akin to old, the age of a man, generation]: Ger. *Welt*; Fr. *monde*; Ital. *mondo*. Any sphere or domain of existence, or even of subjective experience, regarded as a relatively self-included whole.

When used without qualification it generally means the physical realm, nature, especially that part which is nearest man—the earth or globe. It is extended, however, to include the whole universe taken as an object; and, when used with qualifying terms, to mean any object or system of objects as material of inquiry, discussion, or reflection; as the world of nature and man, world of art, of spirit: a realm or sphere, whether physical or intellectual, constituting, for the purpose in hand, a single unified content. See COSMOS; MUNDUS, NATURE, and UNIVERSE (2). (J.D.)

World (in theology). (1) The sphere of actuality conceived to be objective to God and including both material and spiritual phenomena.

(2) In the trinity of world, flesh, and devil; the term is applied to the sphere of secular and unspiritual motives.

For the origin of the world see CREATION, and CREATIONISM. The world in its nature is variously conceived. But in every conception of it, it is the sphere of finite existence. The distinction of temporal and spiritual lies within the finite, the spiritual world as well as the temporal being a sphere of manifested and therefore finite reality. In the expression external world we have the analogy of the world as manifested applied to that which in reality transcends it. (A.T.O.)

World-ground: Ger. *Weltgrund*; Fr. *fondement* (or *principe*) *du monde*; Ital. *fondamento dell' universo*. The basis or underlying reality of the world.

The conception is framed with more or less reference to the following motives or demands of thought. (a) The world as it presents itself to our immediate perception does not disclose the unity, the permanence, or the purpose which the mind requires for an intelligible account of experience; (b) the mind therefore frames a conception of some substance, activity, or principle which it regards as self-existent and ultimate; (c) this self-existent, ultimate principle must further be capable of explaining, or affording a SUFFICIENT REASON (q.v.) for, the world as it appears and all its processes and events. Such a ground was sought by Democritus in the atoms; by Plato in the *eîdêa* and especially in the idea of the Good; by Spinoza in Substance; by Leibnitz in the system of monads; by Hegel in the Idea; by Schopenhauer in the Will. As compared with 'cause of the world' the term world-ground (a) does not ordinarily involve such a separation as is usually implied by cause; and (b) positively implies not merely the external or mechanical relation of efficient cause, but also the more intimate, logical relation of reason.

Literature: SIGWART, *Logic*; LOTZE, *Logic*; and *Metaphysic*; HEGEL, *Logic* (trans. by Wallace), § 121. (J.H.T.)

World-Soul: Ger. *Weltseele*; Fr. *âme du monde*; Ital. *anima del mondo*. A soul of the world; an intelligent, moving force, or directing and organizing principle, sustaining the same relation to the cosmos as the SOUL (q.v.) or PSYCHE (q.v.) sustains to the rest of the individual; the *anima mundi*.

The conception of such an animating and directing agent, of which the individual soul is a part, is found in early Greek philosophers, especially Heraclitus and Anaxagoras (see LOGOS, and NOUS). It was explicitly designated as soul by Plato (*Timaeus*, 34-7), who

attempted to embody in it the opposite principles of unity and plurality, of timeless being and changing process, which he usually contrasted so sharply (see SOCRATIC PHILOSOPHY). It was thus a mediating conception. With the Stoics, similarly, it expressed both the rational and the material character of the universe (see also PNEUMA). It was retained by various scholastics. Abélard rejected the usual interpretation and identified it with the Holy Ghost as the source of spiritual life to individual souls. In more recent times the conception has been employed by Maimon (*Ueber die Weltseele*) and Schelling. The latter means by it 'an organizing principle which makes the world a system.'

Literature: ZELLER, *Plato and the Older Academy*, 341 ff. (contains bibliog. of the Platonic doctrine); DEUTSCH, Abélard (1883), 284 ff.; FISCHER, Schelling. (J.H.T.)

World-view: suggested rendering of the Ger. *Weltanschauung* (not in use in Fr. and Ital.). The general way of regarding the world, more or less philosophically, personal to this or that individual; thus Emerson's world-view was mystical. (J.M.B.)

Worship [AS. *weorthship*; ME. *worthshipe*, worthiness, dignity]: Ger. *Gottesverehrung*; Fr. *adoration, culte*; Ital. *culto, adorazione*. (1) That prostration which arises in presence of a superior being on whom we are absolutely dependent and whom we fear or reverence.

(2) Acts of worship are those through which the feeling is given expression.

The feeling and act of worship involves primarily submission and fealty. It is the attitude of the weak to the strong on whom they are absolutely dependent. The lower forms of worship are therefore largely motivated by abject fear and a desire to propitiate a power which may otherwise be malevolent. It is only in the higher forms of worship that more spiritual and worthy elements enter, such as love, reverence, devotion, gratitude, &c. The form of the ritual indicates as a rule the dominating sentiment of the worship. (A.T.O.)

Worth [AS. *weordh*]: Ger. *Werth*; Fr. *valeur*; Ital. *valore*. (1) A determination which involves any sort of subjective appreciation; equivalent to value.

It will appear from this definition that worth is, in all its forms—hedonic, utilitarian, economic, aesthetic, ethical, social—(a) a function of conation: there is no worth but satisfies or stimulates, or embodies some

impulse; and (b) relative to some sort of subject.

(2) Used more generally for fitness or adequacy of any kind: as logical, i.e. evidential or argumentative, worth; practical worth, i.e. utility, as of means to an end; symbolic worth, i.e. in terms of meaning, signification, or significance in a whole. (J.M.B.)

The expressions worth and value and their negatives are, in their broadest usage, applied to those contents of consciousness which are selected or rejected on the basis of volitional and affective dispositions rather than because of fulfilment of logical demands or norms. Thus the distinction between 'judgments of value or worth' and 'judgments of matter of fact,' between categories of 'appreciation' and of 'description.'

Historically, the distinction attained its present importance through the Kantian dualism between the theoretical and practical reason, according to which judgments of value spring from a *a priori* volitional norms distinct from the norms of pure reason. With the exception of the theory of value developed by Hegelian idealism, this distinction has had a relatively constant place in post-Kantian thought. Herbart and Lotze especially emphasized it by the development of the theory that emotional congruity rather than logical consistency is the determining element in judgments of value.

Popular usage would suggest that this distinction is not ultimate, but rather one which has meaning merely for philosophical methodology. Thus the expression value is used to describe all purposive relations of thought, whether in the most abstract realm of mathematics or in the sphere of practical utilities. Recent important contributions to philosophy have sought to point out the relativity of this distinction. Ormond (*Foundations of Knowledge*) devotes a chapter to the relations of 'judgments of truth and value,' and Royce (*The World and the Individual*) has developed fully the importance of this relative distinction within a monistic idealism. Cf. ORIGIN *versus* NATURE.

This philosophical distinction has proved fruitful in developing a distinctively scientific study of values. Out of the investigations of the psychological basis of economic values by the subjective school of economists (see ECONOMIC SCIENCE) had arisen the need for a more general analysis of values. To the origination of this new field of study, Brentano (*Psychologie vom empirischen Standpunkte*)

largely contributed by a doctrine of psychological dualism which reduced all judgments of value to a fundamental faculty of love and hate. From these sources have developed the psychological theories of value of Meinong and Ehrenfels. This school has definitely formulated the problems of a science of values and made some important contributions towards their solution.

The nature of worth and value. Worths, as constituting a problem for empirical analysis, are to be deduced neither from external utilities nor from nativistically conceived needs or instincts of the subject (Nietsche). Worth defines an attribute neither of subject nor of object, but rather a functional relation between the two. All values are therefore descriptive of such actual or possible relations (Meinong, as cited below, 29; Ehrenfels, as cited below, 65). As to the psychological nature of this relation there is some difference of opinion. Is the process of valuation identical with desire (Ehrenfels), or is the sense of value given in feelings of worth (Werthgefühle), following upon judgmental processes involving the recognition of the existence or non-existence of objects (Meinong)? If of the former character, then the sense of value is measured in terms of the strength of desire, and the strength of desire is determined by the relative increase of pleasure involved. If of the latter nature, then the sense of value is given in modifications of feeling, determined by the existence or non-existence of objects for conative tendencies, or for judgment. It is probable that, while worth is a function of the relation of desire to its object, all immediate sense of value is given in affective states resultant upon the affirmation or inhibition of conative tendencies, for the intensity of desire cannot be measured directly.

Since value is a function of desire or judgment, expressing a relation between subject and object, desire or judgment presuppose dispositional tendencies. If, as according to Ehrenfels, value is a function of desire, and desire is determined by the relative increase of pleasure that results, then affective dispositions are presupposed. If, however, the sense of value is given in modifications of feelings, determined by volitional, judgmental reactions, then volitional dispositions are assumed.

The dispositional concept. In either case the dispositional concept is of great importance in modern theories of value. For, in

the first place, value being a function of the relation of these dispositions to objects, these dispositions, the product alike of individual and social causal processes, are the determinants of the sense of value. All these analysts of the sense of value agree that it cannot be reduced to conscious calculation of pleasures and pains. In the second place, upon the modifications of these dispositions, affective or volitional, depend the mutations of value, and from the laws of their modification spring the empirical laws governing mutations of value in the individual and social consciousness.

In connection with this dispositional concept arises a psychological question of importance (see DISPOSITION). Does it represent a psychological reality, or is it only a way of expressing possibilities and probabilities of worth reactions? Is it of purely physiological significance? Meinong (as cited below, 173) and Ehrenfels (as cited below, 117) conceive it rather in this fashion, denying a corresponding psychological reality. It is, however, worth while noting in this connection that certain other theories of value (Guyau, Krueger) seem to presuppose a development of conscious affective dispositions in the direction of a generalization of affective states, and that such a theory of generalization would make of the dispositional concept a term much more capable of explaining the subjective phenomena of valuation. The relation of desire and conation in general to affective states and the nature of affective or conative dispositions are then among the most important psychological problems of a theory of value. Ehrenfels, indeed, insists at length, and probably with justification, that the question whether value springs from affective or conative dispositions has little influence upon the determination of the empirical laws of value which reflect the modifications and mutations of these dispositions. In fact, he points out in detail the slight changes necessary to make these laws harmonize with either theory. The important problem is rather whether all values and their modifications may be reduced to modifications of these dispositions, whether all values are dispositional values in this monistic sense, and whether the laws governing the mutations of value hold for all values. Opposed to this is the dualistic conception of Schwartz that there are two classes of values—values of 'condition,' determined by desire and feeling, and higher values of the person and the race, determined by *a priori* functions

of the will—a dualism which seems to rest upon a defective analysis of the consciousness of value. It is probable that the highest ethical values are dispositional, refined and specified by the growth of intelligence, by the specification and abstraction of the social consciousness.

Ethical values. Within the general theory of value, based upon the facts of psychological analysis, may be distinguished the special provinces of economic and ethical values. The former develops the laws governing the material instrumental values, the latter the instrumental values (*Wirkungswerthe*), of human dispositions, in the sense defined, for society.

Intrinsic and instrumental values. Empirical analysis, however, discloses the fact that dispositions are valued both as intrinsic and instrumental values (*Eigen- and Wirkungswerthe*). What is the genetic relation of these two classes? Are the intrinsic values original, underived dispositions, valued independently of their instrumental value, of their effects, or are they genetically related to instrumental values? The monistic theories recognize this genetic relation. While it is certain that dispositions are valued as intrinsic without reference to their effects, nevertheless psychological analysis discloses laws according to which instrumental values are constantly passing over into intrinsic and intrinsic into instrumental. This process is called value movement (*Werthbewegung*).

Laws of value movement. It is Ehrenfels' special service (Meinong, as cited below, 72) to have formulated the laws of this movement. There is, in the first place, a mutation of values due to the modification of these dispositions by well-known laws of individual and social psychology, such as habit, association, transference of feeling, and suggestion. In the second place, there is a progressive derivation and subordination of values, growing out of the development of the intelligence and powers of abstraction. The tracing out of teleological and causal dependencies of values leads to the valuation of dispositions as intrinsic instead of instrumental values, and reversely, as instrumental instead of intrinsic. There is likewise a movement from the valuing of external acts to inner dispositions, these dispositions becoming bonds of retention (*Erhaltungs-Glieder*) for adaptive reactions. These laws of value movement and the lapsing from consciousness of intermediate values are also studied by Schwartz and Simmel.

The question arises, whether a fundamental class of intrinsic values can be distinguished. It is clear that only psychological dispositions are intrinsic values, and, in view of the fact of the mutation of values, only the most general classification is possible. A threefold classification into values of 'condition,' 'personal' and 'over-individual' values has been made, but Schwartz's attempt to make this distinction absolute is probably unwarranted. Intrinsic as well as instrumental values suffer mutation (Meinong, as cited below, 72; Ehrenfels, as cited below, 112).

The empirical laws governing the mutations of value are laws both of the individual and social consciousness. Values may thus be individually or successively, ontogenetically or phylogenetically, developed. The struggle for existence among dispositions, which are at once the objects of ethical valuation and the source of value reactions, springs out of the nervous conditions of these dispositions. While there dwells in each the tendency to utmost activity under the given conditions, yet, since the valuing subject is master of only a limited energy of valuation, i.e. nervous energy, the increase of value of any given disposition must necessarily cause others to decrease. In any case increase of value is always relative.

The measurement of value. Consequently both Meinong and Ehrenfels conceive that the law of marginal utility, which has been developed for economic values, holds also for ethical instrumental values. It is a fundamental law of all valuation. In its application to the ethical sphere it has been called the law of Grenzfrommen. And, since there are no absolutely underived values, but all are either individually or successively, ontogenetically or phylogenetically, derived and have become the 'bond of retention' for extrinsic values, it follows that the law is conceived to govern intrinsic values also. The working of this law in the sphere of social ethical worths gives rise to a constant value movement which manifests itself in the creation of three grades of value always distinguishable at any empirical stage of the movement. These are described as aspiring, normal, and outlived (*aufstrebende, normale, and entfremdete*), and correspond to the changes in dispositions. This is called the ethical value movement.

Distinction between ethical and moral values. Both of these writers give to the moral values a sort of central position in the

entire sphere of ethical human values. Moral values are those dispositions which, in the social ethical value movement, have been segregated as relatively permanent intrinsic values. Thus Ehrenfels conceives, arising partly out of the ethical value movement described above, a second moral value movement, which may be defined as a tendency to the valuation of *activities* as such, which have their 'bond of retention' in their utility for the general welfare. This segregation of a central sphere of relatively permanent good and bad activities is the product of growing powers of abstraction and of the impersonal participation of the individual in the social value consciousness. In view of this distinction between ethical and moral values it becomes clear how a relative permanence of moral concepts is consistent with mutations in ethical values. Dispositions change more rapidly than the social valuation of abstract activities. The moral movement is an integrating movement within a wider ethical development.

Absolute values. In this connection arises the question of the existence of absolute values and of a single dispositional value corresponding to a single immanent end of the ethical movement. The logical consequence of the methodological principles described is a negative answer, entirely in line with the critical conclusions of such writers as Simmel and Münsterberg. Since all values are dispositional values, and dispositions are subject to the empirical laws of mutation, it follows that neither in the individual nor in the social consciousness can a value be in any sense absolute. It follows also that a single affective disposition, corresponding to a single ethical end, is psychologically inconceivable. Such monistic formulations of the ethical end as the 'general welfare,' 'self-realization,' 'highest possible energy of valuation,' can only be understood as regulative concepts brought in from an external philosophical speculation.

The more philosophical problems of a theory of value arise when the attempt is made to connect the empirical laws of value, determined by psychological analysis, with the more general conceptions of science and philosophy. The psychological analysis of value makes an artificial abstraction of the affective, volitional aspects of consciousness. A more general theory of value seeks to correlate anew these abstracted processes, scientifically, with the biological processes (Ehrenfels),

philosophically with the rational processes of the self.

In connection with the latter arise such questions as (a) the relation of the individual to the social value series; (b) the significance of the worth postulates of the self and their relation to the causal mutations of values; and (c) the harmonization of the idealistic measure of value, in 'extension and intension' (Bradley, Guyau, Krueger), with the empirical measure, developed above. Since value expresses a relation between subject and object in the last analysis, it becomes a problem for epistemology and metaphysics.

(W.M.U.)

Wrath [AS. *wradh*]: Ger. *Zorn*; Fr. *courroux*; Ital. *cruccio*. Moral ANGER (q. v.), which is in some degree justified, and which is entertained by one of superior or exalted nature or station; called also *ire* (as in the case of God), and righteous anger (as in the case of the Hebrew prophets). (J.M.B., G.F.S.)

Wright, Chauncey. (1830-75.) An American writer on science and philosophy, born at Northampton, Mass. His writing was mainly in the form of papers in current journals—collected in certain of them are his *Philosophical Papers* (ed. by Norton). He held no academic post, but lectured in 1875 on psychology at Harvard University. He died

at Cambridge, Mass., where much of his life was spent.

Writer's Cramp: Ger. *Schreibkrampf*; Fr. *crampe des écrivains*; Ital. *granchio degli scrivani, mogigrafia* (E.M.). A characteristic professional or occupation neurosis affecting those who have overstrained the neuromuscular mechanism of writing.

As a rule no other co-ordinations are affected than those involved in writing, the patient being able to use a razor or needle, to perform on a musical instrument, and the like. Every attempt to write, however, brings on a cramp; and although the attempt is made to hold the pen in a new position, and other devices are resorted to, the desired movements fail to be executed. In severe cases other delicate movements are also involved, and slight tremors, neuralgic pains, and much mental distress form accompanying symptoms. Analogous professional neuroses are piano-player's, violinist's, telegraphist's, auctioneer's cramp, &c. See Bernhardt, 'Die Erkrankung der peripherischen Nerven,' in *Nothnagel's Spec. Pathol. u. Therapie* (1897), 160 ff. (J.J.)

Writing: see HANDWRITING.

Wrong [AS. *wrang*]: Ger. *Unrecht*; Fr. *mal*; Ital. *torto*. The violation of that which constitutes right, or a right, constitutes wrong, or a wrong. See RIGHT (various topics). (J.M.B.)

Wrong (in law): Ger. *Verletzung, Unrecht*; Fr. *injustice, délit*; Ital. *ingiusto, ingiustizia*. An invasion of another's right, causing him damage or breaking the peace of the state.

The term is broader than TORT (q. v.). It covers violations of contract and public wrongs (those breaking the peace of the state), i.e. crimes (see Holland, *Jurisprudence*, chap. xiii. 281). It involves the notion of culpability. He is blameworthy who fails to fulfil his contract obligations; and he also who acts in such a way as naturally, though undesignedly, to damage another, when a person of ordinary intelligence ought to foresee the consequence (Holmes, *The Common Law*, 108). A narrower meaning has been assigned to 'injury' (Puffendorf, *De Officio Hominis et Civis*, Lib. I. chap. ii. 15). Courts are for the redress of wrongs, and only act in exceptional cases for their prevention, as by an injunction against a threatened wrong (Markby, *Elements of Law*, chap. xx. § 852).

(S.E.B.)

X

XENIA — XENOPHANES

Xenia [Gr. *ξένια*, gifts to a guest from his host]: Ger. *Xenien*; Fr. *xénies*; Ital. *xenia*. The influence of pollen of one species upon the maternal tissues of another species after hybrid fertilization. Cf. TELEGONY.

The term was introduced by W. O. Focke, 1881. Cf. Delage, *L'Hérédité*, 233. (C.S.M.)

Xenocrates. (396–314 B.C.) Born at Chalcedon; a pupil of Plato, whom he accompanied to Syracuse. After the master's death

he went with Aristotle to Asia Minor. Returned to Athens and succeeded Speusippus as head of the Academy.

Xenophanes of Colophon. Lived in the 6th century B.C. He is distinguished as the first Greek monotheist and founder of the Eleatic School, named after Elea, in Lower Italy, where the philosopher finally settled. See PRE-SOCRATIC PHILOSOPHY (Eleatics).

Y

YOGA PHILOSOPHY — YOUTH

Yoga Philosophy: see ORIENTAL PHILOSOPHY (India).

Youth: see ADOLESCENCE.

Z

ZEISING'S PRINCIPLE — ZENO

Zeising's Principle: see GOLDEN SECTION.

Zend-Avesta: Ger. *Zend-Avesta*; Fr. *Zend-Avesta*; Ital. *Zend-Avesta*. The ancient Bible of the Zoroastrians, composed of a fragment of the works accredited to Zoroaster and constituting, in connection with the Pahlavi books, the sacred literature of the Parsees.

The surviving fragment of the Avesta forms about one-third of the original ascribed to Zoroaster, which is said to have been burned at the time of the Alexandrian conquest. The surviving part is about one-tenth the size of the Christian Bible. See ZOROASTRIANISM.

Literature: GELDNER, Text of the Avesta (1884); DARMESTETER and MILLS, *Zend-Avesta* (Eng. trans., 1880–7); Oriental Religions Series, iv, xxiii, xxxi. (A.T.O.)

Zeno of Elea. (Early in the 5th century B.C.) Son of Teleutagoras, he became the pupil and friend of Parmenides. He is called by Aristotle the inventor of dialectic. See PRE-SOCRATIC PHILOSOPHY (Eleatics), and cf. SOPHISM.

Zeno is the author of the sophism called the 'Achilles argument,' to prove that motion is impossible; i.e. Achilles, the fastest possible runner, could never overtake the tortoise, the slowest possible goer, if the latter had ever so short a start; for the distance between them consists of an infinite series of parts, and when Achilles, by traversing one of these parts, comes to where the tortoise was, the latter will always have gone further. Cf. SPACE (passim).

Zeno the Stoic. (b. cir. 340 B.C.) A merchant until his thirtieth year, he was led, as a result of shipwreck, to visit Athens.

Read the works of Xenophon and Plato; admired Socrates; became a disciple of Crates the cynic, then of Stilpo of the school of Megara, and of Xenocrates and Polemon in the Academy. About 310 B.C. he founded a school in the *Στοὰ ποικίλη* (hence 'Stoic'), and after fifty-eight years of teaching committed suicide.

Zone [Gr. ζώνη, a girdle]: Ger. *Zone*; Fr. *zone*; Ital. *zona*. An area or region; e.g. the motor zone or area of the brain; the language zone or general area within which anatomical injury leads to disorders of speech. The retina may be divided into zones, and in disorders of vision sight may be defective in certain limited zones.

In hysteria there are characteristic hysterogenic zones, pressure upon which produces not only pain but a convulsive attack (see *Hysteria*). Zones as well as spots of anaesthesia and of hyperaesthesia are found in hysteria and other nervous disorders. (J.J.)

Zones of His: Ger. *Längszonen von His*; Fr. *zones de His*; Ital. *zone di His*. The four longitudinal thickenings of the central nervous system.

The two dorsal zones are especially associated with the entering sensory nerves. The two ventral zones contain all the nerve-cells whose axons form ventral or lateral nerve-roots.

W. His was the first to recognize the morphological significance of these zones, which dominate the structure of the nervous system. He termed the ventral zones *Grundplatten*, the dorsal zones *Flügelplatten*. The present term was introduced by Minot, *Human Embryol.* (1892). (C.S.M.)

Zoology: see *BIOLOGICAL SCIENCES*.

Zootheism [Gr. ζῷον, animal, + θεός, God]: Ger. *Zootheismus*; Fr. *zoothéisme*; Ital. *zoo-teismo*. The representation and worship of deity under the form of an animal, the animal being regarded not as the symbol of the deity, but as actually inhabited by him.

The later stages of zootheism are seen in the Egyptian reverence for animals, in which, however, the animal has become largely symbolic. The crude form of zootheism is supposed to represent the lowest and most primitive form of religious belief.

Literature: ANDREW LANG, art. *Religion*, in *Encyc. Brit.* (9th ed.). (A.T.O.)

Zoroaster. One of the great teachers of

the East, the prophet of Iran, whose teachings are contained in the Avesta. The dates of his life are unknown; the ancient authorities differ as widely as 5,000 years as to his birth. He probably taught in Eastern Iran, especially in Bactria. Probably he began teaching at thirty, and was slain in battle at seventy years of age. He is regarded as one of the Magi, and the author of a new creed. Zoroastrianism was the national religion of ancient Persia until Alexander the Great invaded the country, and again until the rise of Mohammedanism. See *ZOROASTRIANISM*, and *ORIENTAL PHILOSOPHY* (Persia).

Zoroastrianism [Pers. *Zorothustra*]: Ger. *Lehre von Zoroaster*; Fr. *Zoroastrisme*; Ital. *Zoroastrismo*. The religious system of the Persians, founded by Zoroaster and involving a dualistic struggle between the powers of light and darkness personified in the good and evil deities Ormuzd and Ahriman and their attendant devs or spirits. See *ORIENTAL PHILOSOPHY* (Persia).

Zoroastrianism is mistakenly called fire-worship, inasmuch as fire is used only as a symbol of the good spirit. The dualism, though personified in two opposing deities, is not absolute, for the evil deity, while coeval with Ormuzd, will be finally destroyed. Man was created with free will, and his struggle may end in final triumph over evil. The power of Zoroastrianism was broken by the Alexandrian invasion and was further shattered by the rise of Mohammedanism. It is now the religion of about 90,000 Parsees.

Literature: see references under *ZEND-AVESTA*; also A. HOVELACQUE, *Le Avesta, Zoroastre, &c.* (1880); W. GEIGER, *Ostiranische Kultur im Alterthum* (1882). (A.T.O.)

Zwingli, Ulrich or **Huldreich**. (1484-1531.) Studied at Wesen, Vienna, and Basel. Ordained priest, and elected pastor of Glarus, 1506; called in 1516 to St. Mary's at Einsiedeln; also in 1518 to the cathedral at Zürich, where he remained until his death; introduced the Reformation movement into Zürich, 1524; led the movement in other Swiss cantons; took part in the conference at Berne, 1528, where the mass was abolished. Killed in a battle between the Roman Catholic and Protestant cantons while stooping to minister to a wounded soldier. One of the most influential leaders of the *REFORMATION* (q.v.).

GENERAL INDEXES

I. INDEX OF GREEK TERMS

[This Index and that of Latin terms were prepared by Professor W. M. Urban.]

THE reference numbers are printed in four different kinds of type: those in black type (123) are terms which occur as main topics in the work; those in modern face type (123) are the formally recommended equivalents; those in italic (123) are terms of which some exposition or discussion is given; and those in old style (123) are those which have passing mention only, but which are mentioned in a way judged of sufficient importance to require citation.

Under each kind of type the citations from vol. ii follow those from vol. i, and are preceded by the Roman numeral ii (which is not repeated); all other citations are from vol. i.

With the page number the column of the page is given in a small figure; where the small figure is omitted the reference is to both columns.

ἄδης, 436¹, 465².
 ἀδιάφορα, 427¹, 533¹, ii. 475¹.
 ἀδιάφορον, ii. 430².

III. INDEX OF GERMAN TERMS

[Prepared by P. H. Fogel, M.A., and J. W. L. Jones, Ph.D.]

THE reference numbers are printed in four different kinds of type : those in black type (123) are terms which occur as main topics in the work ; those in modern face type (123) are the formally recommended equivalents ; those in italic (123) are terms of which some exposition or discussion is given ; and those in old style (123) are those which have passing mention only, but which are mentioned in a way judged of sufficient importance to require citation.

Under each kind of type the citations from vol. ii follow those from vol. i, and are preceded by the Roman numeral ii (which is not repeated) ; all other citations are from vol. i.

With the page number the column of the page is given in a small figure ; where the small figure is omitted the reference is to both columns.

IV. INDEX OF FRENCH TERMS

[Prepared by W. J. Shaw, M.A.]

THE reference numbers are printed in four different kinds of type: those in black type (123) are terms which occur as main topics in the work; those in modern face type (123) are the formally recommended equivalents; those in italic (*123*) are terms of which some exposition or discussion is given; and those in old style (*123*) are those which have passing mention only, but which are mentioned in a way judged of sufficient importance to require citation.

Under each kind of type the citations from vol. ii follow those from vol. i, and are preceded by the Roman numeral ii (which is not repeated); all other citations are from vol. i.

With the page number the column of the page is given in a small figure; where the small figure is omitted the reference is to both columns.

abaque, 1¹.
abattement, 263².
aberration chromatique, 1².
aberration mentale, 2¹.
aborigènes, 2².
aboulie, 2², ii. 816².
absence, 3¹.
absolu (1'), 3¹.
absolution, 4¹.
absolutisme, 4².
absolutisme esthétique, 4².
absorption, 4².
absorption en Dieu, ii. 692¹.
abstraction, 6¹.
abstrait, 5¹.
abstraite (idée), 5¹.
absurde, 6².
académie, 6².
acataphasie, 53², 158².
accélération (loi d') de déve-
loppement, 7¹.
accent, 7¹.
accentuation, 7².
accident(-el), 7², 157¹.
accommodation, 7², 8.
accord, 176².
accord (de trois sons), ii. 714².
accord (sentiment d'), 334².
accord parfait, ii. 714².
accoutumance, 436¹, ii. 681¹.
accumulées (valeurs), 154².
accusation, 532².
achromatique (sensation), 146².

 Zoroastrisme, ii. 829¹.

V. INDEX OF ITALIAN TERMS

[Prepared by Helen Green Baldwin.]

THE reference numbers are printed in four different kinds of type: those in black type (123) are terms which occur as main topics in the work; those in modern face type (123) are the formally recommended equivalents; those in italic (123) are terms of which some exposition or discussion is given; and those in old style (123) are those which have passing mention only, but which are mentioned in a way judged of sufficient importance to require citation.

Under each kind of type the citations from vol. ii follow those from vol. i, and are preceded by the Roman numeral ii (which is not repeated); all other citations are from vol. i.

With the page number the column of the page is given in a small figure; where the small figure is omitted the reference is to both columns.

abbozzo, ii. 481¹.
